B. cycla, Chard Beet, is inferior to the two last in the size of its roots, but is remarkable for the thickness of the ribs of its leaves, which are white, yellow, green, orange coloured, or deep crimson, in different varieties. It is cultivated like the Common Beet, but the leaves only are used in soups, or their ribs are cut out and stewed like sea-kail. They have however an earthy taste, which is not in the power of cookery wholly to remove, on which account they are little esteemed. The French call this species Poirée à Cardes. It is said to have been introduced to France from Portugal; but its native station is unknown.

B. maritima, Sea-Beet, unlike the three last, is a prostrate plant, with numerous entangled branches and a tough woody root. It is found abundantly on many parts of the southern coast of England, and is a common European shore-plant, preferring a chalky soil. Its leaves are small, ovate, deep green, crenelled, rather sharp-pointed, flat, succulent, and placed on long stalks. Its flowers are green and arranged in spikes, each being subtended by a small leafy bract. It is a perennial, and one of the most valuable plants known for spinach; its leaves when dressed are extremely delicate and well-flavoured, and easily reduced into that pulpy substance which constitutes the great merit of good spinach. It thrives in a garden without any sort of care, and is rather a handsome plant when growing among rubbish, for its leaves are a particularly rich green, and not liable to be scorched.

by the sun, or to be injured much by insects. It is increased by seeds, which it yields in abundance. [Beet, in Arts and Sc. Div.]

BETEL, the leaf of an intoxicating kind of pepper. [Piper.]

BETEL-NUT PALM. [Areca.]

BETHY'LUS, a genus formed by Cuvier, and placed by him under his second order of Birds (*Les Passereaux*), in the first tribe (*Dentirostres*), and in the first family (*Laniadæ*). He says that there is but one species known (*Lanius Leverianus* of Shaw, *Lanius picatus* of Latham), and that the Great Shrike (*Lanius corvinus* of Shaw) approaches it, thoug[illegible]. *corvinus* has the bill more compressed.

Vieillot has changed the generic name to *Cissopis*, and Illiger makes it a *Tangara*.

The genus is thus characterised by Vieillot:—Bill short, robust, swollen, a little compressed towards the end; upper mandible notched and curved at the point: gape ciliated; the third and fourth quills longest; outer toes united at their base.

Le Vaillant has figured this bird (plate 60) under the name of Pie Pie-Greiche. White and black are the only colours of its plumage, distributed like those of the magpie which it is said to resemble in miniature in Guyana and Brazil, where it is a native.

BETHY'LUS, a genus of Hymenopterous Insects of the family *Proctotrupidæ*. Its principal distinctive characters are—antennæ geniculated, 13-jointed in both sexes; the head is depressed and the prothorax very elongate and almost triangular. The wings have only one large marginal cell, not closed; abdomen conical; legs short, femora thick.

These little four-winged flies, which are remarkable for their large depressed heads, are not very unlike ants in their appearance, and are found in flowers and sometimes on the leaves of shrubs, to which they resort in search of small caterpillars, which they store up in cells to nourish their future progeny. The principal haunts of these insects are dry sandy situations.

BETONICA. [Betony.]

BETONY, the common name of the *Stachys Betonica* [Stachys], which was formerly described under the name of *Betonica officinalis*.

BE'TULA, a genus of trees or shrubs, belonging to the natural order *Betulaceæ*. It is characterised by its flowers growing in catkins, the scales of which are thin and three-lobed, and by the scales subtending three flat fruits, each furnished with two styles, and expanded into a thin wing on either side; these fruits are what are vulgarly called birch-seeds. The species are, with one exception, found beyond the tropic in the northern hemisphere; the species of the southern hemisphere is a little evergreen plant called *B. antarctica*, of which little is recorded except that it inhabits Tierra del Fuego.

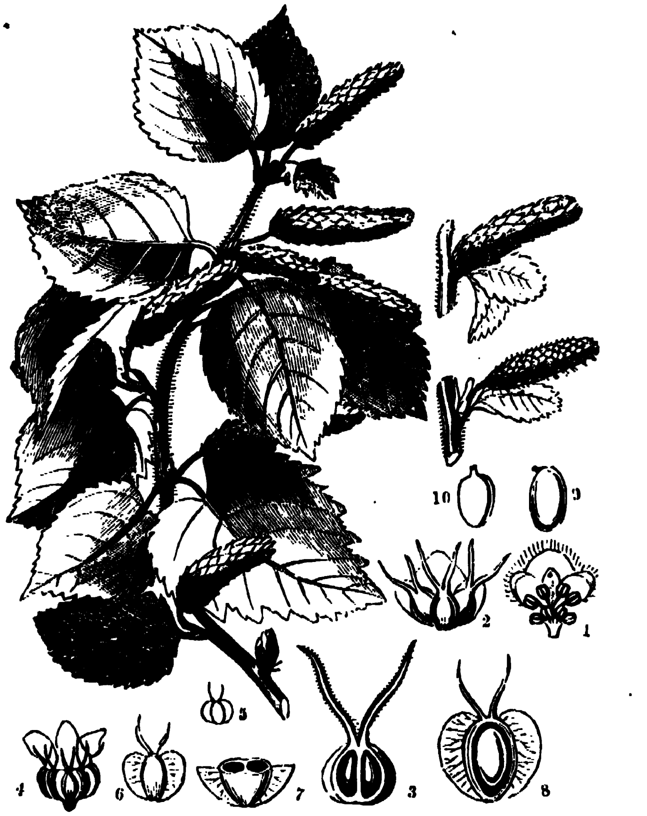
The more remarkable species of this genus may be conveniently disposed according to their prevailing geographical distribution.

European Birches.

B. alba, the Common Birch. Branches erect, when young covered with a short close down never smooth, and warted; leaves with a somewhat rhomboidal form, ovate, generally doubly serrated, with downy footstalks, acute, but not tapering to the point; catkins pendulous. A native of Europe from the most northern to the most southern countries, in the latter however not appearing except on mountains at a considerable elevation; on Ætna it does not occur below 4762 feet above the sea, according to Philippi. It is also found eastward in Asia, as far at least as the Altai Mountains. Although this species is not much valued for its timber, it is extremely useful for many other purposes. Russia skins are said to be tanned with the empyreumatic oil of its bark, from which the peculiar odour of such leather is derived. Cordage is obtained from it by the Laplanders, who also prepare a red dye from it; the young shoots serve to nourish their cattle, and vinegar is obtained from the fermented sap. The inhabitants of Finland use the leaves for tea, and both in Lapland and Greenland strips of the young and tender bark are used as food. From the timber are manufactured hoops, yokes for cattle, bowls, wooden spoons, and other articles in which lightness without much durability is sufficient; baskets and hurdles are often made of parts of its shoots; and from its rising sap, extracted by means of openings cut into its alburnum in the spring, and fermented, a kind of wine is obtained which is of an agreeable quality, but will not keep. During the siege of Hamburg by the Russians in 1814, almost all the birch-trees of the neighbourhood were destroyed by the Bashkirs and other barbarian soldiers in the Russian service, by being tapped for their juice.

The Birch naturally grows in poor sandy soil, on which it thrives fully as well as in that of a more fertile kind. It is said to attain sometimes the height of 70 feet, with a diameter of 2 feet; in England it does not acquire such considerable dimensions. As it approaches both its northern and southern limits it gradually decreases in size, conformably to the laws which regulate vegetable development. Its bark is said to be very durable.

B. pendula, the Weeping Birch. Branches drooping, when young perfectly smooth, and marked with little pearly specks; leaves with a somewhat rhomboidal form, ovate, either doubly or singly serrated, acute, but not tapering to the point, sometimes slightly hairy; catkins pendulous. Very common in different parts of Europe, along with the last, in the properties of which it appears to participate, and with which it is often improperly confounded. It differs from the Common Birch not only in its weeping habit, but also in its young shoots being quite smooth, bright chestnut brown when ripe, and then covered with little white warts. The *Betula pontica* of the nurseries is a slight variety, with a few straggling hairs on the leaves and leafstalks, and a less drooping habit.



Common Birch (*Betula alba*).

1, The inside of a barren scale, with the anthers attached; 2, inside of a fertile scale, with the ovaries attached; 3, an ovary cut through perpendicularly; 4, inside of a scale, with three ripe fruits; 5, a ripe fruit of the natural size; 6, the same magnified; 7, a transverse section, and 8, a perpendicular section of the same; 9, a ripe seed; 10, an embryo.

B. pubescens, the Downy Birch. Branches erect, covered all over with very close down; leaves heart-shaped, ovate, taper-pointed, doubly and sharply serrated, very downy. A smaller species than the first, found in the bogs of Germany: a variety of it is called *Betula urticifolia* in gardens.

B. nana, the Dwarf Birch. Leaves orbicular, crenated, with strongly marked veins on the under side; catkins upright. A small bush, found in Lapland and the mountainous parts of other northern countries; it even stretches across the whole continent of Asia as far as Unalaschka. To the people of the south this plant has no value, but to the Laplanders it affords a large part of their fuel; and its winged fruits are reported to be the favourite food of the ptarmigan. The place of this is occupied in America by a species called *Betula glandulosa*.

Asiatic Birches.

B. Bhojpattra, Indian Paper Birch. Leaves oblong, acute, with nearly simple serratures, somewhat heart-shaped at the base; their stalks, veins, and twigs hairy; ripe catkins, erect, cylindrical, oblong; bracts smooth, woody, two-parted, blunt, much longer than the fruit, which has narrow wings. A tree found on the Alps of Gurwal and Kumaon, where it was discovered by Dr. Wallich, who informs us that its thin delicate bark furnishes the masses of flexible laminated matter, of which great quantities are brought down into the plains of India for lining the tubes of hookahs. The Sanscrit name of the substance is Boorja. (Wall. 'Plant. As. Rar.,' vol. ii. p. 7.) The bark of this species is of a pale cinnamon colour. It is nearly allied to *B. papyracea*.

B. acuminata, the Tapering-Leaved Birch. Leaves ovate, lanceolate, somewhat simply serrated, taper-pointed, smooth, dotted beneath, leafstalks and twigs quite smooth; ripe catkins, very long, pendulous, cylindrical, crowded; their rachis and the bracts, which are auricled at the base, downy. Found on many of the mountains of Nepaul, and in the great valley of that country, following the course of rivers.

B. nitida, Shining Birch.

B. cylindrostachya, Cylindrical Spiked Birch. These two last species are found in Kumaon.

American Birches.

B. populifolia, the Poplar-Leaved or White American Birch. Catkins pendulous; branches perfectly hairless, drooping, very much covered with resinous warts; leaves triangular, taper-pointed, doubly-toothed, on long weak stalks. This species is more an object of ornament than of utility. It rarely grows more than 20 or. 25 feet high, except in very rich soils, when it is said to become somewhat taller. It is a native of the northern parts of North America, from the lower parts of New York, New Jersey, and Pennsylvania, to Canada. Michaux says that its bark cannot be divided into thin plates like that of the Paper-Birch or common European species. It is very like the European *B. pendula*, from which the characters we have assigned it are sufficient to distinguish it.

B. nigra (*B. rubra*, Michaux; *B. lanulosa*, A. Mich.), the Red Birch. Branches covered closely with a short thick down, which they do not lose till the second year; leaves angularly rhomboidal, very deeply doubly serrated, acute, with the axils and veins of the underside of the leaf downy; stipules narrow-ovate, membranous, smooth, soon dropping off. A native of the borders of rivers, where it grows associated with planes, maples, and willows, in the southern provinces of the United States, delighting as much in heat, according to Michaux, as many other species do in cold, and therefore the best adapted for planting in the southern parts of Europe. It is a handsome species, growing as much as 70 feet high, and from 2 to 3 feet thick, and is remarkable for its bark not being white and shining, but brown, dotted with white, and slightly wrinkled. The limbs of the tree are large, and the branches terminate in long flexible pendulous twigs. Cask hoops are manufactured from its shoots when about an inch in diameter; and all the brooms used in the streets of Philadelphia, which are far better than those of Europe, are prepared from its tough and elastic twigs. In this country it is generally called *B. angulata*.

B. excelsa (*B. lutea*, Mich.), the Yellow Birch. Catkins erect, short, thick, nearly sessile; branches exceedingly downy when young; leaves rhomboidal, acute without any tapering, finely and regularly serrated, or nearly entire; on very downy stalks; stipules large and membranous. Found chiefly in the coldest parts of North America along with the Paper-Birch; south of the Hudson River it becomes rare. Michaux states that it is principally in good alluvial soil that it thrives, in company with black and hemlock spruces and ashes; its greatest height is from 60 to 70 feet, with a diameter of something more than 2 feet. It is said to be a handsome tree, with a straight trunk, often clear of branches as far as 30 or 40 feet from the ground. It is remarkable for the bright golden yellow of its bark, which shines as if it had been varnished. It is most like *B. nigra*, from which its thicker and more hairy catkins and simply serrated leaves distinguish it, independently of other characters.

B. papyracea, the Paper or Canoe-Birch. Catkins thick, pendulous, on long stalks; branches generally more or less downy when young, sometimes hairy; leaves ovate, occasionally heart-shaped, regularly or irregularly serrated, smooth or downy. This, the most valuable of all the species of Birch, is a native of North America, where it grows in great quantities, not extending beyond 73° to the north nor 43° to the south, according to Michaux. The slopes of hills and valleys, where the soil is of good quality, are said to be its favourite stations: in such places it often acquires the height of 70 feet.

Its wood is sometimes used in North America for cabinet makers' work; but it is not of much value for exposure to the weather, as it soon decays if subjected alternately to damp and dryness. Its bark is the part which is the most esteemed; this part is said to be so durable that old fallen trees are stated to be frequently found with their form so well preserved that one would think them perfectly sound, but upon examining them it is found that the whole of the wood is rotted away, and nothing is left but the sound and solid case of bark. This part is used for a number of useful purposes; loghouses are sometimes thatched with it; little boxes, cases, &c., and even hats are manufactured from it; but its great value is for making canoes. For the purpose of obtaining pieces sufficiently large for such a purpose, we are informed by Michaux that the largest and smoothest-barked trees are selected. In the spring two circular incisions at the distance of several feet are made, and a longitudinal incision on each side; then by introducing a wedge of wood between the trunk and bark, the latter is easily detached. With threads prepared from the fibrous roots of the White Spruce-Fir (*Abies alba*), the pieces of bark are sown together, over a light frame-work of wood, and the seams are caulked with the resin of the Balm of Gilead Fir. Canoes of this sort are so light as to be easily transported on the shoulders of men. It is said that one capable of carrying four persons and their baggage only weighs from 40 to 50 pounds.

B. lenta (*B. carpinifolia*, A. Mich.), the Soft, Black, or Cherry-Birch. Catkins short, erect; branches quite smooth; leaves thin, cordate, oblong, tapering to a point, simply or doubly serrated, downy when young, smooth afterwards; stipules very large and membranous. None of the American birches produce timber so valuable as this; whence one of its American names is Mountain Mahogany. Its wood is hard, close-grained, and of a reddish brown; it is imported into this country in considerable quantity, under the name of American birch, for forming the slides of dining-tables, and for similar purposes. It is abundant in the midland states, as in New York, New Jersey, and Pennsylvania, but more to the south it only appears on the summits of the Alleghanies. Deep rich soil is what it prefers; and when it attains its greatest dimensions, which are as much as 70 feet of height, and 3 feet of diameter, it is a handsome tree, budding remarkably early in the spring, when its leaves are covered with a short thick coat of down; this disappears later in the season, and leaves them of a bright and lively green. It grows with unusual rapidity. It is rarely seen in this country, although it is perhaps one of the best suited to our climate. The thinness of its leaves, combined with their oblong figure, distinguishes this from all the other species.

BETULA'CEÆ, *Birchworts*, the Birch Tribe, a natural order of Apetalous Dicotyledonous plants. It was formerly comprehended, along with other groups, in what were called *Amentaceæ*, because it bears its flowers in amenta, or catkins; but it is distinguished from all those which agree with it in this particular, by its flat, one-seeded, two-celled, membranous fruit, and pendulous ovules. All the species are either trees or shrubs, with the fertile flowers in one catkin and the barren in another, and they have in general the main lateral veins of their leaves running straight from the midrib to the margin, without curving inwards. They are found in the colder parts of the world, or in mountainous regions in hot countries. The only genera belonging to this order are *Alnus* and *Betula*. [ALNUS; BETULA.] Lindley places the order between *Myricaceæ* and *Altingiaceæ*.

BEUDANTITE, a black mineral, with a resinous lustre and rhombohedral crystals. It contains oxides of lead and iron. It is found at Horhausen on the Rhine.

BEWICK'S SWAN, the *Cygnus Bewickii*. [SWANS.]

BIAPHO'LIUS (Leach), a genus of Bivalve Shells, indistinctly known, and which Rang considers to be identical with the genus *Hiatella* of Daudin. [PYLORIDIANS.]

BIB, a Fish. [MORRHUA.]

BI'DENS, a genus of plants belonging to the natural order *Compositæ*, the suborder *Corymbiferæ*, tribe *Senecionideæ*, subtribe *Heliantheæ*, division *Bidentideæ*. It has monogamous discoidal heads, sometimes radiant; the florets of the ray neuter ligulate, of the disk, hermaphrodite, tubular; the receptacle flat; the involucre of two rows, the outer row spreading; the branches of the style surmounted by short cones; the fruit compressed, angular, rough at the edges, the angles terminating in 2-5 stiff retrorsely hispid bristles. The genus has been named *Bidens* from the two bristles which most frequently surmount the teeth. A great number of species belonging to this genus have been described, but they are generally inconspicuous weeds. They have been found in Europe and North and South America. Two are natives of Great Britain in marshy and watery places, *B. bipartita* and *B. cernua*. The latter is the *Coreopsis Bidens* of Linnæus. (Babington, *Manual*; Lindley, *Natural System*.)

BIGBONE LICK, a place in Kentucky (United States), where great numbers of fossil mammalia occur in a dark-coloured marshy soil, covered by gravel and resting on blue clay. The bones of *Elephas primigenius* and *Mastodon maximus* are very numerous. With them lie bones of *Magalonyx Jeffersonii*, *Bos bombifrons*, *Bos Pallasii*, and *Cervus Americanus*. (Rogers, *On American Geology; British Association Reports for* 1834.)

BIGENERI'NA, D'Orbigny's name for a genus of *Foraminifera*, which he originally described as minute Cephalopods. There are two subgenera; the first consisting of the *Bigenerinæ* properly so called, with a central opening, and the other of the *Gemmulinæ* (D'Orbigny) with a marginal opening.

BIGNO'NIA, a genus of plants named by Tournefort after the Abbé Bignon, librarian to Louis XIV. It forms the type of the monopetalous order of Exogens, *Bignoniaceæ*. It has a campanulate 5-toothed rarely entire calyx; the corolla with a short tube, a campanulate throat, and a 5-lobed bilabiate limb; the stamens four, didynamous, with the rudiments of a fifth; lobes of the anther divaricate; stigma bilamellated; capsule siliqui-formed, 2-celled, with the dissepiment parallel with the valves; the seeds in two rows, imbricate, transverse, with membranous wings. Nearly 100 species of this genus of elegant plants have been described. They are usually climbing shrubs furnished with tendrils, having opposite, single, conjugate, ternate, pinnate, or digitate leaves. The flowers are mostly in terminal or axillary panicles. The corollas are trumpet-shaped, and are coloured variously, white, yellow, orange, purple, violet, or rose.

All the species of this genus are splendid plants while in blossom, and deserve a place in every collection. Most of them are climbers, and adapted for training up rafters and pillars, but they only grow freely in stoves. A mixture of loam and peat is best adapted for their growth, and cuttings will strike readily under a hand-glass in heat, either in mould or sand. The species known by the name of this genus which is most abundant in our gardens is the *Bignonia radicans*. This and some other species of *Bignonia* are now referred to the genera *Spathodea* [SPATHODEA] and *Tecoma* [TECOMA]. It is one of the few species capable of living in the open air against a wall in this country.

B. æquinoxialis has square glabrous branches, glabrous conjugate leaves, oblong lanceolate leaflets, simple axillary tendrils, 2-flowered peduncles, terminal ones racemose, follicles linear. It is a native of Guyana. It is applied by the negroes to swellings of the feet, with which they are troubled.

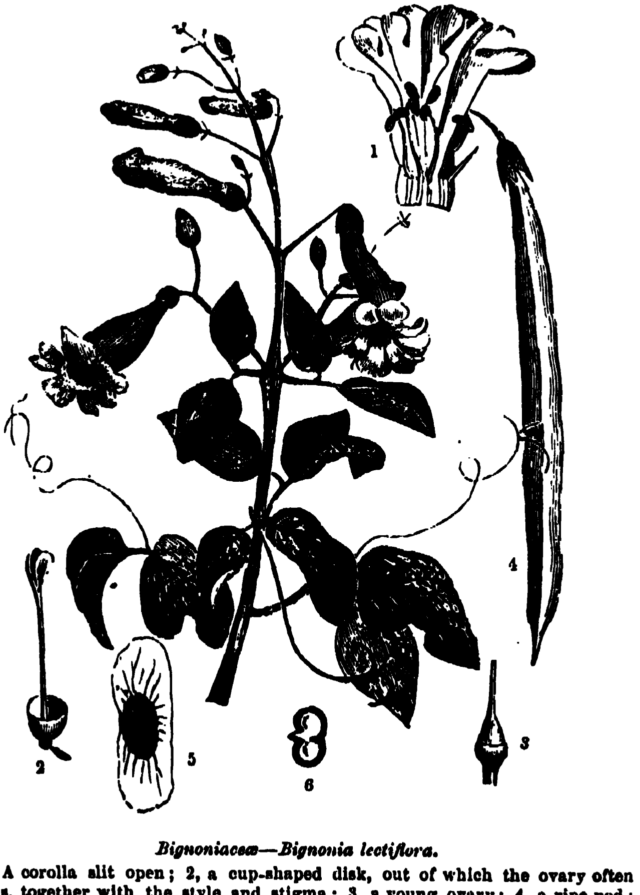
B. leucoxylon is a tree, and has quinate leaves; ovate-lanceolate, acuminate, glabrous leaflets; terminal, solitary, or twin flowers. This plant is a native of Jamaica, on the banks of rivers. It has white flowers, not unlike those of *Datura Stramonium*, which come out before the leaves. The wood is of a green or yellow colour, and is sometimes brought into the market under the name of ebony. It is said to be an antidote to the poison of Manchineel.

B. Chica is a climbing plant, and has abruptly-bipinnate leaves; conjugate elliptic-ovate, acuminate, deeply-cordate, glabrous leaflets; axillary pendulous panicles. It grows on the banks of the Orinoco. A red matter is extracted from its wood by the Indians, with which they paint their bodies. It is called Chica, and has been used in this country as a dye.

B. alliacea has tetragonal branches, conjugate leaves, coriaceous elliptic leaflets, simple tendrils, axillary 5-flowered peduncles, a 5-toothed calyx. It is a native of Guyana and the West Indies. It has large white flowers, and is distinguished from all the other species by its peculiar garlic odour; hence the French name Liane à l'Ail.

(Don, *Gardener's Dictionary;* De Candolle, *Prodromus;* Burnett's *Outlines; Cyclopædia of Plants.*)

BIGNONIA'CEÆ, *Bignoniads*, the Bignonia Tribe, are Monopetalous Dicotyledonous plants, with irregular flowers, a pod-like fruit, winged seeds without albumen, and usually a climbing habit. They are mostly shrubs, inhabiting the hotter parts of Asia, Africa, and America, and unknown in Europe except in a cultivated state; some of them are trees of considerable size. They generally are remarkable for the large size and rich or delicate colouring of their trumpet-shaped flowers. No sensible properties of much importance have been recognised among them. Several are valuable for their timber, which possesses extreme hardness. According to Lindley the number of genera in this order is 44, and the species 450. They are allied to *Gesneraceæ* and *Crescentiaceæ*. [BIGNONIA; ECCREMOCARPUS; CATALPA; TECOMA; JACARANDA.]



Bignoniaceæ—Bignonia lectiflora.

1, A corolla slit open; 2, a cup-shaped disk, out of which the ovary often grows, together with the style and stigma; 3, a young ovary; 4, a ripe pod; 5, a seed; 6, an embryo extracted from the integuments of the seed.

BIKH, or BISH, is the name given amongst the Hindoos to a most powerful and destructive vegetable poison. Dr. Wallich refers the plant to the *Aconitum ferox*. [ACONITUM.] It is also called Vish, Visha, or Atavisha.

BILBERRY, a berry-bearing shrub, found on the moors of most countries in Europe. [VACCINIUM.]

BILE, an animal fluid of a greenish colour, viscid consistence, and bitter taste.

The organ by which the bile is secreted is the liver. The liver is distinguished by two peculiarities: first, it is the largest gland in the body; and secondly, it is provided with two distinct sets of veins. The veins that receive the blood from the viscera of the abdomen, that is, from the organs more immediately concerned in the process of digestion, unite together into a large trunk named the vena portæ. This vein penetrates into the substance of the liver, and ramifies through it in the manner of an artery; at the same time the liver receives a large quantity of arterial blood by the hepatic artery. [LIVER.] The ultimate branches of the vena portæ terminate partly in a set of vessels termed the hepatic ducts, which contain the bile, and partly in a set of vessels termed the hepatic veins, by which a large portion of the blood of the vena portæ is transmitted by the ordinary course of the circulation into the vena cava, the great vein that returns the blood from all parts of the body to the right side of the heart. [CIRCULATION OF THE BLOOD.]

This arrangement is peculiar. There is no other gland in the body in which the disposition of the blood-vessels is at all analogous: there is no other instance in which a vein is sent to a gland and distributed to it in the manner of an artery. This peculiarity has naturally led physiologists to infer that the vein in this case performs the ordinary functions of an artery; that it carries on the process of secretion, and eliminates its product, the bile, out of venous blood.

But whatever doubts physiologists may entertain by which of the two great vessels of the liver the bile is secreted, the consent is universal that the liver is the gland by which this fluid is formed. When duly elaborated in this organ, the bile is received from the secreting vessels by exceedingly minute tubes, the union of which constitutes the excretory duct of the gland, which is termed the hepatic duct. The hepatic duct passing on towards the duodenum, which, physiologically considered, is a second stomach [DUODENUM], communicates with a small membranous cyst or bag, called the gall-bladder, a reservoir for the bile. The duct of the gall-bladder, called the cystic duct, unites with the hepatic duct, and both together form a single tube, termed the choledoch duct, which pierces the duodenum. Thus the hepatic duct, carrying the bile away from the liver, either conveys it into the gall-bladder by means of the cystic duct, or transmits it immediately into the duodenum by means of the choledoch duct. The bile which flows immediately into the duodenum is called the hepatic bile; that which is contained in the gall-bladder is called the cystic bile. There is a striking difference in the external characters of the two, cystic bile being of a much deeper colour, and much more viscid, pungent, and bitter than hepatic bile; but the difference in their chemical properties, if there be any, has not been ascertained: hepatic bile, on account of the difficulty of collecting it in sufficient quantity, has not been analysed, while some portion of bile is generally found in the gall-bladder after death.

From actual experiment it would appear that the secretion of bile is continually going on in the living system. In whatever circumstances an animal is placed—if the orifice of the choledoch duct be laid bare—the bile is always seen to be flowing drop by drop into the intestine. It is observed to flow much faster during the process of digestion than when the stomach is empty; and there is reason to believe that, during the digestive process, the hepatic bile is secreted in much larger quantity than when the stomach is empty, and that it is then conveyed directly into the duodenum. The gall-bladder fills when the stomach is empty, and when the stomach is full the gall-bladder becomes comparatively empty. The gall-bladder, however, is seldom if ever completely emptied. Vomiting contributes more perhaps than any other action of the system to the expulsion of its contents. Magendie states that he has often found it completely empty in animals that died from the effects of an emetic poison.

The physical characters of the bile are as follows:—In colour it is always a deep brown, but when seen in thin layers it has a brownish-yellow tint. It is very fluid, being viscid only in new-born infants. The specific gravity varies from 1.032 to 1.040. On examining with the microscope bile from the gall-bladder, with which of course a certain amount of mucus is mixed, there are observed:—1, Transparent or grayish round vesicles, about the 700th of a line in diameter; they disappear on the addition of alcohol or ether, and are removed by filtration. 2, Conical yellow bodies, about the 140th of a line in length, and about the 300th or 400th of a line in breadth, apparently devoid of nuclei; these are epithelial cells from the gall-bladder. 3, Here and there irregular dark granules, which disappear on the addition of a solution of potash, apparently pigment cells. 4, Occasionally minute crystals of cholesterin, occurring as colourless rhombic tablets.

Chemically the bile is composed of several elements which have a tendency to arrange themselves during chemical analysis in very various forms. Not only are the four organic elements, carbon, hydrogen, oxygen, and nitrogen present, but also sulphur, phosphorus, sodium, potassium, calcium, and iron. The union of the organic elements in different proportions will account for the various substances such as picromel, bilin, choleic acid, colic acid, taurine, &c., which chemists have described in their analyses of biles. According to Dr. Kemp the organic portion of ox-bile may be represented by the formula 48 carbon, 42 hydrogen, 13 oxygen, and 1 nitrogen. The following analyses of ox-bile and human bile, by Thenard and Berzelius, will serve to show the nature of bile as well as the progress of chemical inquiry on this subject when contrasted with more recent analyses. According to Thenard the composition of bile is as follows:—

Ox-Bile.

Water	700
Picromel and Resin	84·3
Yellow matter	4·5
Soda	4
Phosphate of Soda	2
Muriate of Soda	3·2
Sulphate of Soda	0·8
Phosphate of Lime	1·2
Oxide of Iron	a trace.
	800·0

Human Bile.

Water	1000
Yellow insoluble matter	2 to 10
Albumen	42
Resin	41
Soda	5·6
Salts the same as in Ox-Bile	4·5

According to Berzelius, the following is the composition of Human Bile:—

Water	908·4
Picromel	80
Albumen	3
Soda	4·1
Phosphate of Lime	0·1
Common Salt	3·4
Phosphate of Soda with some Lime	1·0
	1000·0

It will be seen from these analyses that the chief part of the organic elements was found in the form of picromel. It was in the year 1838 that Demarçay announced that bile consisted essentially of an organic acid combined with soda. He termed the acid choleic, and obtained it in the following manner: bile, from which the mucus had been precipitated by alcohol, was evaporated on the water-bath, and 10 parts of the dried residue were dissolved in 100 parts of water, to which 10 parts of hydro-chloric acid had been added. Allowing evaporation at a moderate temperature to proceed, it was observed that a dark green oil collected on the surface, while at the same time the fluid became turbid. On removing the oil and allowing the fluid to rest for some time, it gradually became clear, with the precipitation of a green deposit. This dark-green bitter precipitate is Demarçay's choleic acid, and is regarded by him as constituting nine-tenths of the solid constituents of the bile. It is still mixed with margaric acid, cholesterin, pigment, &c. After their removal it forms a yellow spongy matter, which rapidly absorbs oxygen from the atmosphere, is very bitter, slightly soluble in ether, soluble in water, and very soluble in alcohol. The choleate of soda, obtained by adding an alcoholic solution of soda to an alcoholic solution of choleic acid, and then passing a current of carbonic acid through it to remove the excess of soda, possesses all the characters of bile; it yields on evaporation a brown resinous mass, and is soluble in water and in alcohol.

When choleic acid is boiled with hydrochloric acid it yields ammonia, taurine, and choloidic acid; the latter being insoluble is deposited. The formulæ usually assigned to choleic acid, taurine, and choloidic acid differ only slightly from the formula given above for the organic portion of ox-bile.

But it has been recently shown by Redtenbacher that taurine contains as much as 25 per cent. of sulphur.

As an instance of modern chemical analysis we give the two following analyses. The bile in these cases was obtained from healthy men, killed by severe accidents:—

	1.	2.
Water	86·00	85·92
Solid constituents	14·00	14·08
Choleate of Soda	10·22	9·14
Cholesterin	0·16	0·26
Margarin and Olein	0·32	0·92
Mucus	2·66	2·98
Chloride of Sodium	0·25	0·20
Tribasic Phosphate of Soda	0·20	0·25
Basic Phosphate of Lime „ „ Magnesia	0·18	0.28
Sulphate of Iron	0·02	0·04
Peroxide of Iron	traces	traces

Platner succeeded in obtaining choleic acid and choleate of soda in a crystallised form. Sugar has also been recently demonstrated to exist in the bile. Gmelin and Strecker have also obtained from dried bile an acid which they call choleic, and other substances have been procured from the bile of lower animals.

One of the uses which the bile serves in the economy is to produce a specific change upon the aliment in a certain stage of the digestive process. The first change which the food undergoes after it has been swallowed is the reduction of it by the stomach into a fluid mass, the appearance of which varies considerably according to the nature of the food. This fluid mass is termed chyme, which when accumulated in a certain quantity is sent from the stomach into the duodenum. In the duodenum the food undergoes a further change, and is converted from chyme into the substance called chyle. These two fluids are distinguished from each other by specific characters. [DIGESTION.] That the bile is the main agent in producing the change by which chyme is converted into chyle is proved by a decisive experiment performed by Sir B. Brodie.

This physiologist applied a ligature around the choledoch duct of an animal so as completely to prevent the bile from entering the duodenum, and then noted the effects produced on the digestion of the food immediately before and immediately after the operation. The experiment was repeated several times, and the result was uniform. The production of the chyme in the stomach took place as usual, but the conversion of the chyme into chyle was immediately and completely interrupted. Not the smallest trace of chyle was perceptible either in the duodenum or in the vessels which take up the chyle when formed, namely, the lacteals.

It was at one time supposed that after the bile had performed this function that its compounds were thrown off from the system by the bowels. But that the bile is not merely an excrementitious fluid, intended to remove effete matter from the blood, but a secretion essential to the animal economy, was rendered almost certain by the experiments of Berzelius, Theyer, and Schlosser, which showed that the human fæces contained much too small a quantity of a substance resembling bile, to justify the idea that it was evacuated in this manner. A further proof that the bile is absorbed and not excreted is afforded by an examination, made by Enderlin, of the ash yielded by the contents of the different portions of the intestinal canal of a hare. He found that the ash from the contents of the duodenum alone effervesced on the addition of an acid, thus showing that the choleate of soda (which yields the carbonate on incineration) is absorbed before reaching the jejunum. Schwann also established this opinion beyond a doubt, by a series of well-devised experiments on dogs. He tied the ductus choledochus, and at the same time formed a fistulous opening in the gall-bladder, by which the bile escaped externally. His most important conclusions are—1st, that when the bile does not get into the bowel its absence is generally perceptible in dogs about the third day by a marked diminution in weight; and, 2nd, that unless the channel for the conveyance of bile to the duodenum is re-established, symptoms of deficient nutrition, wasting, debility, &c., ensue, and death is the ultimate consequence.

Upon this ground it was suggested by Liebig that probably all the carbonaceous substances of the food were converted into bile before being again taken up into the circulation and converted into carbonic acid for the supply of animal heat. It is however certain that a portion of the bile, in the form of colouring matter, passes off through the intestines, and also that in certain diseases it is thrown off in considerable quantities with the contents of the bowels. It can also be shown that the quantity of biliary matter formed in the liver does not contain more than one-sixth or one-eighth of the quantity of carbon that is thrown off from the lungs in the form of carbonic acid.

BILIMBI, the Malayan name of the acid fruit of a species of *Averrhoa*. [AVERRHOA.[

BILLARDIE'RA, a genus of plants named after Jean Jacques Julien Labillardière, a French botanist, who visited Syria, and afterwards Australia, in D'Entrecasteaux's Expedition, and wrote the 'Novæ Hollandiæ Plantarum Specimen,' in two vols., 4to. The genus belongs to the natural order *Pittosporaceæ*, and has a calyx of five acuminate sepals, five petals with approximate claws, which are convoluted at their edges, forming a campanulate flower; an ellipitical berry terminated by a style. The species are called Apple-Berries; and George Don enumerates eight. They are climbing shrubs, natives of Australia and Van Diemen's Land. The fruit which they bear is eatable.

B. longiflora has climbing branches, the younger ones scarcely pubescent; the leaves lanceolate, entire; the pedicles 1-flowered, glabrous, one half shorter than the flower; the berries almost globose, torose, glabrous. This plant is "a fast grower and abundant flowerer; and when in fruit its fine blue berries make a handsome appearance." (Loudon.)

The other species are desirable shrubs for the conservatory. They thrive well when planted in an equal mixture of loam and peat. Cuttings will readily root in sand under a bell-glass. They may be also raised from seed, which they produce in abundance.

(*Cyclopædia of Plants*; G. Don, *Gardener's Dictionary*.)

BILLBERGIA, a genus of plants belonging to the natural order *Bromeliaceæ*, named after Billberg, a Swedish botanist. Several species are cultivated in our stoves. They are all natives of South America. One of the species, *B. tinctoria*, yields a colouring matter, which is used for dyeing in Mexico.

BILLY-BITER, a local name for the Blue Tit. [PARUS.]

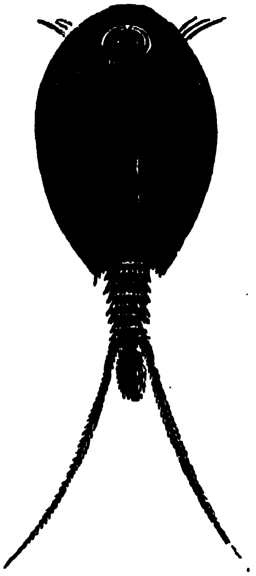
BILOCULI'NA (D'Orbigny), the name of a genus of *Foraminifera*, Les Milioles of Ferrussac.

BIMANA, the first order of the class *Mammalia*, which includes the single genus and species *Homo sapiens*—Man. [MAN.]

BIND-WEED. [CONVOLVULUS.]

BINNY. [BARBEL.]

BINO'CULUS, Geoff., Leach, a genus of Entomostracous *Crustacea; Apus*, Scop., Cuv., Latr.; *Limulus*, Müll., Lam.; *Monoculus*, Linn., Fabr. Of these names *Apus* is that now generally adopted. The species of this genus are gregarious, and occur often in innumerable quantities. Sometimes whole swarms are swept away by violent winds, and have been seen to fall like rain. The spring and the commencement of summer are the seasons when they are most commonly found; and they often appear suddenly in great numbers in accidental rain-water puddles where they never have been before seen, as well as in ponds. The generic name *Binoculus* appears to be unnecessary, and that given by Scopuli should be restored: the true *Limuli* form a marine genus, making a natural group of different form and habits. Linnæus's genus *Monoculus* comprehends *Apus*, *Limulus*, and other crustaceans. The species figured is *Apus productus*, Latreille (*Lepidurus productus*, Leach; *Monoculus Apus*, Linn.). Only one species occurs in England, *A. cancriformis* the Shield-Shrimp. It is about 2½ inches long, and 1½ inch in diameter; it is of a brownish-yellow colour, clouded with marks of a deeper hue. The segments of the abdomen are each studded over with numerous short stout hooked spines of a dark brown colour; while the long caudal appendages are furnished with numerous short hairs, or setæ. It is a rare creature, and only a few localities for it have been recorded. [ENTOMOSTRACA.] (Baird's *History of the British Entomostraca.*)



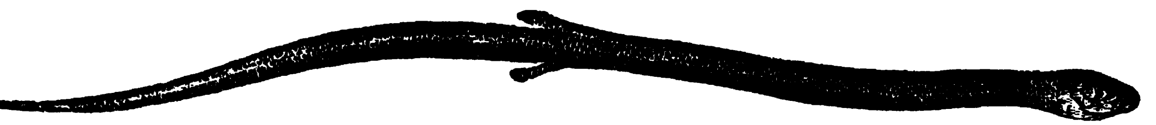
Apus productus.

BIPAPILLA'RIA, a genus of Marine Molluscs established by Lamarck upon a species figured and described in the manuscript notes of Péron.

BIPES, a genus of Reptiles belonging to the order *Saura*, or Lizards. Cuvier dissected one of the species *Bipes lepidopodus* of Lacépède), and found that, though its posterior and only apparent pair of feet had the external form of two oblong and scaly plates or processes, the integument covered a femur (thigh-bone), a tibia and fibula (leg-bones), and four metatarsal, or finger-bones, but no phalanges (terminal finger-bones). He also states that one of the lungs is less by one-half than the other.

This genus is an example of one of those gradations by which nature glides from one type of form into another, and is a link between the Saurians (lizards) and the Ophidians (serpents).

The *Bipes lepidopodus* of Lacépède is now referred to the genus *Pygopus*, of which the following characters are given: scales of the back keeled; preanal pores numerous; the hinder limbs elongated; the pupil circular.



Pygopus lepidopodus.

Lacépède describes the body and tail of *P. lepidopodus* as being nearly cylindrical, very slender, and a little like those serpents called by the French Orvets, of which our common Blind-Worm or Slow-Worm (*Anguis fragilis*, Linnæus) is an example; and which, though without limbs, have some of the rudiments of such members in the skeleton. The upper part of the head of *P. lepidopodus* is covered by seven large scale-plates disposed around an eighth, which is a little larger than the others. Each eye is surrounded by small scaly globules. The gape is sufficiently large, and the teeth are equal and small. The flat long tongue is without a notch. The auditory orifice is near the commissure of the lips. The scales which cover the upper part of the body are lozenge-like, striated, and small, especially those which cover the most elevated part of the back; but the scales of the under part of the belly and the tail are hexagonal and smooth, and those of the two middle longitudinal ranks are larger than those of the lateral ranks. At each extremity of the curve formed by these tubercles is to be seen a foot, in which no finger is to be distinguished externally, and which is surrounded by very small scales on its lower part, and by scales a degree less small on its upper surface. The colour is greenish, varied with some very small black blotches.

"This reptile," says Lacépède, "like the other species of *Bipes*, ranks between the oviparous quadrupeds and the serpents; it is related to the latter by its general form, as well as by the figure, proportion, and distribution of the scales, while it approaches the former by its auditory apertures, and by the hollow tubercles near the anus." It is a native of Australia.

Dr. Gray has described a second species of *Pygopus* as *P. squamiceps*.

Bipes as an English word is applied to the *Anguis bipes* of Linnæus, the *Scelotes bipes* of Gray. It belongs to the order of Lizards, and is a native of the Cape of Good Hope.

BIPHORES, a division of the shell-less Acephalous *Mollusca*, according to the arrangement adopted in the 'Règne Animal' of Cuvier. It includes the genera *Salpa* and *Thalia*. [TUNICATA.]

BIRCH-TREE. [BETULA.]

BIRD-CHERRY, one of our native wild fruits. [CERASUS.]

BIRD-LIME, a glutinous vegetable product, also called *Biscia*, and related to Caoutchouc. It is obtained principally from the inner bark of the holly, from the berries of the mistletoe, and also other plants. It is prepared from the holly bark by bruising, long boiling in water, and fermentation; the mass is again boiled in water, and evaporated to a proper consistence. In different countries various processes are employed.

Water does not dissolve bird-lime, but separates from it some mucilage and extractive matter, and a little acetic acid. The alkalies dissolve it, and so does sulphuric ether very perfectly. Dilute acids soften it, and dissolve a portion; concentrated sulphuric acid blackens and carbonises it, while nitric acid renders it yellow, converting a part of it into oxalic and malic acids, and separates resin and wax; chlorine bleaches and hardens it; alcohol dissolves some resin and acetic acid. When heated, bird-lime melts, swells, takes fire, and burns rapidly.

It is probable that this substance results from the decomposition of the cellulose of the cells of the plant from which it is obtained. It is well known that in nearly all decompositions of cellulose, carbon remains in excess, and this agrees with the composition of viscin, which contains, according to Macaire Prinsep, Carbon 75·6, Hydrogen 9·2, Oxygen 15·2. (Schleiden, *Principles of Botany.*)

BIRD-PEPPER. [CAPSICUM.]

BIRD'S-FOOT SEA-STAR. [PALMIPES.]

BIRD'S-FOOT TREFOIL. [ORNITHOPUS.]

BIRD'S-NEST. [NEOTTIA.]

BIRD'S-NEST, YELLOW. [MONOTROPA.]

BIRDS, in Latin *Aves*, in Greek Ὄρνιθες (whence *Ornithology*), a class of Verteberated, Oviparous, Feathered Bipeds, generally formed for flight. We say generally, because, though their mechanism is in its most perfect development designed for enabling them to support their bodies in the air and to make progress in that medium, it is also calculated for motion on the ground and for perching on trees. Some families indeed are framed entirely for moving on the ground, and others for that motion and for making their way both on the surface of the water and even for a short period below it, without the power in either case of raising themselves into the air.

Skeleton.

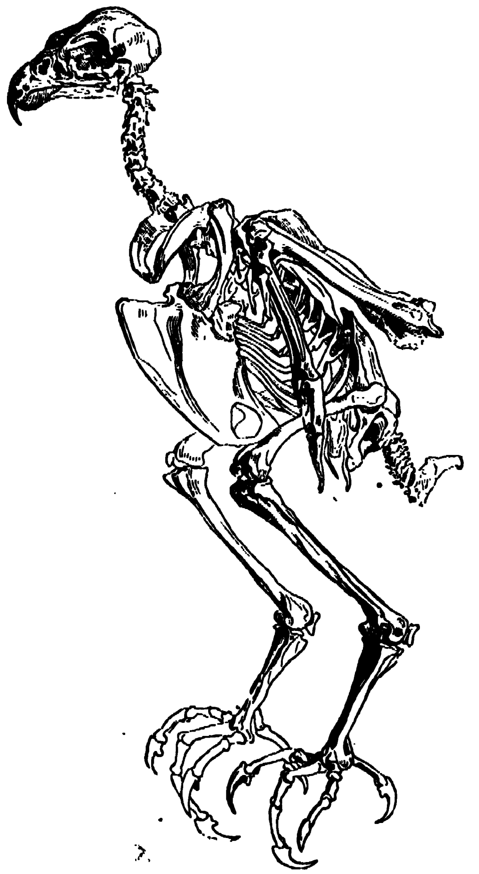
Skull (Cranium). The first peculiarity which strikes an observer, when comparing the skulls of birds with those of mammifers, is the absence of sutures in the former, the proper cranial bones being consolidated into one piece. The skull of birds is articulated to that part of the vertebral column called the neck by a single condyle or joint, which is situated at the front margin of the great occipital opening (foramen magnum), through which the brain, becoming elongated as it were into the spinal cord, descends into the vertebral column. It is this beautiful adaptation of structure to the wants of the animal that gives such a freedom of motion to the head, especially in a horizontal direction. Take for example the Wryneck (*Yunx torquila*), which, as those who have surprised the bird on the nest will readily admit, can writhe her head round so as to look the intruder in the face, hissing all the while like a snake; by this 'terrible show' many a birds-nesting novice is frightened away. Perfect repose in a bird seems hardly to be enjoyed without turning back the head and nestling the beak between the wings; this attitude the articulation above mentioned enables the bird to command with the least possible effort.

The orbits are very large in proportion to the skull, to which last the lower jaw is joined by a somewhat square bone (os quadratum) not far from the ear. A small bone rests on the square bone at one end, while the other end comes against the palate. When therefore the square bone is brought forward by depressing the lower jaw, and also by muscles adapted to the purpose, the small bone presses up against the palate, and this raises the upper jaw, which contrary to the rule in the structure of mammifers is in birds, with but few exceptions, thus gifted with motion.

Both jaws are completely destitute of true teeth, the want of which is, as we shall presently see, amply compensated. The upper jaw is either formed of one piece distinct from the skull and articulated with it, as in the parrots; or it is connected with it by means of yielding elastic bony plates, as in most other birds. These elastic plates admirably protect the bill (the upper part of which may be considered as an elongation of the intermaxillary bones) and the skull from the shocks of the former organ when used in pecking violently against hard substances.

In a few instances the upper jaw is entirely immovable. Blumenbach gives the Rhinoceros Bird and the Cock of the Wood (*Tetrao Urogallus*) as instances.

Bones of the Neck and Trunk.—The upper limbs, or, to speak more correctly, the anterior extremities of birds are calculated for flight, and entirely useless as prehensile organs, because the bird depends principally upon its bill to gather its food. To give a greater freedom of action to this organ, it was necessary, as the bones of the back have hardly any motion (the dorsal vertebræ being often anchylosed or immovably fixed by a continuation of bony secretion), that the neck should be long and flexible; and eminently flexible it is. In the mammifers the number of cervical vertebræ (neck-bones) is seven; the Cameleopard (Giraffe) has no more, and the Elephant and Whale have no less. Cuvier indeed gives the Sloth nine. Professor Thomas Bell however has satisfactorily made out that the additional two are bones of the back, not of the neck. But, in Birds, nature has made up for the deficiency of motion in the back (a deficiency absolutely necessary to the comfortable existence of the animal, inasmuch as the back is the point of support to the wings) by the free grant of cervical vertebræ, according to the wants which the peculiar habits of particular birds require. Thus the Raven has 12 neck-bones, the Domestic Cock 13, the Ostrich 18, the Stork 19, and the Swan 23, the largest number it is believed yet detected, while the smallest amounts to 10. The articulation is so contrived as to produce the greatest mobility, and that the contrivance is complete is proved by the ability of a bird to touch every point of its body with its bill.



The vertebræ of the back are from 7 to 11 in number. There are no true lumbar vertebræ, for they are consolidated into one piece with the pelvis (os innominatum) which is elongated, broad, and simple; and does not unite below, as in mammifers, to form what is called the symphysis pubis, but has the lateral portions distinct from each other. This is the general rule. The pelvis of the ostrich forms an exception for it is joined below like that of most quadrupeds. In most of th quadrupeds the rump-bone (os coccygis) is prolonged into a true jointed tail. In birds it never is, but is very short, although it supports the large tail-feathers (rectrices).

Ten pairs of ribs are said to form the maximum among birds; these, the true ribs, are joined to the breast-bone (sternum) by small intervening bones. The false ribs (those which do not reach the breastbone) have a forward direction. There is a peculiar flat proces

directed upwards and backwards attached to the middle pairs of the true ribs.

The breast-bone (sternum), a part of the greatest consequence, being the point of attachment for the most powerful of the muscles which set the wings in action, is composed of five pieces strongly joined together, and prolonged below into a crest (crista) for that purpose. The greater or less development of this crest or keel, and the greater or less ossification of the component parts of the breast-bone, depend upon the wants of the bird. Those birds whose flight is strongest and most continuous have the crest very large, and the breast-bone pieces very firmly cemented together, as any one may see who will examine the breast-bone of a hawk, or eagle, or that of a humming-bird; while in the ostrich and cassowary this crest is entirely absent, and the breast-bone presents a uniformly arched surface, somewhat like that of a Highlander's target.

In the crane and in the male wild-swan there is a cavity in the anterior part of the breast-bone for the reception of the involuted wind-pipe (trachea). The connection of the wings with the trunk is managed by means of the two clavicles, and of that peculiar fork-like elastic bone commonly called the merry-thought (furcula). This apparatus operates as an antagonist power to the action which would bring the wings together in flight, did not these bones, especially the merry-thought, keep the shoulders asunder. The greater or less development of this bone depends on the exigencies of each particular case. In birds whose flight is long and rapid it is strong, with the branches widely arched and carried forwards on the body; in birds which do not fly at all, in the ostrich, cassowary, and emu, for instance, the bone becomes a mere rudiment. "In the ostrich," as Macartney observes, "the two branches are very short, and never united, but anchylosed with the scapula (shoulder-blade) and clavicle (collar-bone). In the cassowary there are merely two little processes from the side of the clavicle which are the rudiments of the branches of the fork. In the emu there are two very small thin bones attached to the anterior edge of the dorsal ends of the clavicles by ligaments; they are directed upwards towards the neck, where they are fastened to each other by means of a ligament, and have no connection whatever with the sternum."

The wing-bones are the homologues or representatives of the arms or upper extremities of man and of the monkeys. The following are the bones composing the wing of a bird:—The arm (os humeri); the fore-arm, consisting of two bones (ulna and radius); the wrist (carpus), formed by two bones; the metacarpus, also made up of two bones; a thumb, or rather the rudiment of one, there being but a single bone; and two fingers, the finger next the thumb consisting of two portions, and the other only of one. To this hand are attached the primaries, or greater quill-feathers; the secondaries are affixed to the fore arms; and the arm supports feathers of inferior strength and development, called tertiaries and scapulars. The bone which represents the thumb gives rise to the bastard quills, and along the base of the quills are ranged the largest of those feathers which are denominated wing-coverts. Such is the structure of the 'sail-broad vans' which waft the condor over the Andes.

Bones of the Lower or Posterior Extremities.—These consist of a thigh-bone (femur); leg-bones (tibia and fibula), for there are two, though the fibula is very small, and becomes anchylosed to the tibia; one metatarsal bone (at the lower end of which there are as many processes as there are toes, each process furnished with a pulley for moving its corresponding toe); and the toes. Of these, three generally are directed forwards and one backwards. This back toe, or great toe, is wanting in some birds. In the swallows it is directed forwards; in the climbing birds the outer toe as well as the back toe are directed backwards. The number of joints is generally progressive; the back toe has 2, the next 3, the middle toe 4, and the outer toe 5 joints.

"The stork, and some others of the *Grallæ* (Waders)," says Macartney, "which sleep standing on one foot, possess a curious mechanism for preserving the leg in a state of extension, without any or at least with little muscular effort. There arises from the fore part of the head of the metatarsal bone a round eminence, which passes up between the projections of the pulley, on the anterior part of the end of the tibia. This eminence affords a sufficient degree of resistance to the flexion of the leg to counteract the effect of the oscillations of the body, and would prove an insurmountable obstruction to the motion of the joint if there were not a socket within the upper part of the pulley of the tibia to receive it when the leg is in the bent position. The lower edge of the socket is prominent and sharp, and presents a sort of barrier to the admission of the eminence that requires a voluntary muscular exertion of the bird to overcome, which being accomplished, it slips in with some force like the end of a dislocated bone."

Muscles of Motion and External Integuments.

"The muscles," writes Blumenbach, "in this class are distinguished by possessing a comparatively weak irritable power, which is soon lost after death; and by their tendons becoming ossified as the animal grows old, particularly in the extremities, but sometimes also in the trunk."

The pectoral muscles, as we might expect from the form of the sternum, exhibit, generally speaking, the greatest development. They are three in number, taking their rise chiefly from the ample breast-bone, and all being brought to bear on the head of the arm (humerus). Of these, the first or great pectoral is said, as a general proposition, to weigh more than all the other muscles put together. Rising from the keel or crest of the breast-bone, the merry-thought, and last ribs, it is inserted in that rough linear elevation which may be observed on the bone of the arm of most birds. This bone it strongly depresses, and so produces the rapid and powerful motions of the wing, which, acting on the surrounding air, carries the bird forward in its flight. As an antagonist to the great pectoral muscle, the middle pectoral, which lies under it, and whose office it is to elevate the wing, puts forth its tendon over the point where the merry-thought is joined to the clavicle and shoulder-blade. This point of junction acts as a pulley for the tendon which is inserted in the upper part of the bone of the arm; and by this contrivance the elevating power is situated on the lower surface of the body. The third or small pectoral, aids the great pectoral in depressing the wing. Thus some birds are enabled to dart away with the rapidity of an arrow, while others soar to a height invisible to the gaze of man.

We have already seen that the pelvis is prolonged backwards to a considerable extent. This formation furnishes room for the attachment of the muscles which set the posterior extremities in motion, and enables them to perform the functions of walking, hopping, swimming, climbing, and perching. To this end there are a set of muscles which go from the pelvis to the toes. One of the flexor or bending tendons given off from a muscle which comes from the bone of the pubis runs in front of the knee, and all the flexors go behind the heel, so that the mere weight of the bird will bend the toes. Any one may satisfy himself that this operation is purely mechanical, and not the result of muscular action, by making the experiment on a dead bird; when he will find that the flexion of the knee and heel will at once bend the toes. This admirable contrivance, useful as it generally is, shows itself in the most striking manner when brought to bear on the limbs of those birds which roost in trees. When all the voluntary powers are suspended, such a bird enjoys the most profound repose, and the most secure position on its perch, without an effort.

The integuments of birds are composed of the same parts as those of the mammifers, with the addition of feathers, the peculiar covering common to the whole class. The beak is covered with horn, and at its base, as in the birds of prey, there is a fleshy part called the cere. The lower extremities are protected above by a scaly skin, and the bottom of the foot and toes by a callous modification of the same integument. Some, the turkey for instance, are furnished with hair in certain situations. The feathers vary infinitely. When a bird has just left the egg its covering is a downy kind of hair, several little bundles taking their rise from one common bulb. This is the origin of the future feather. A dark cylinder soon makes its appearance, from the upper extremity of which the sprouting feather emerges, while the lower extremity receives the blood-vessels which supply the vascular nourishing pulp of the barrel. When this pulp has performed its office, and the stalk and other parts of the feather are fully developed, it shrivels up into the well-known substance which every one finds in a quill when he cuts it for the purpose of making a pen. The details of the development of the feathers are highly interesting, and have been described at length by F. Cuvier in the 'Mémoires du Museum,' tom. xiii., and also in the article 'Aves' in the 'Cyclopædia of Anatomy and Physiology.'

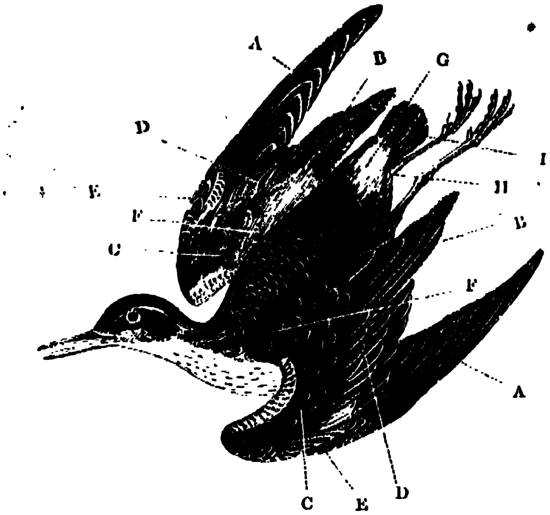
The care which nature takes for the development of that particular part of the plumage first which the wants of the particular bird demand is remarkable. A young partridge runs off as soon as it is hatched to pick up the pupæ of the ant, which the parent bird scratches up for it. Some time elapses before it is necessary that it should fly; we accordingly find that the body from the moment of its birth is protected with a close-set downy covering, while all the strength is thrown into the thighs, legs, bill, and neck. The wings are gradually developed afterwards. A young thrush or a young blackbird is hatched nearly naked, and while its body presents only a few scattered bunches of weak downy hair-like feathers, great progress may be observed in the formation of the quills and other wing-feathers; because from the habits of the bird it is necessary that it should be able to fly as soon as it leaves the nest.

As a general rule the plumage of the cock bird far exceeds in brilliancy that of the hen; and in all such cases the young at first put on the more sombre garb of the mother. When the cock and hen are without much difference in this respect, the young have a particular distinguishing plumage of their own.

Birds moult or shed their feathers. The summer dress in many species varies from that of the winter.

The mode in which the plumage changes is well described in the 'Transactions of the Zoological Society' by Yarrell; and the same able zoologist has shown in the 'Philosophical Transactions,' and in the 'Proceedings of the Zoological Society,' that the putting forth of the plumage of the male bird is not confined to the female past the age of reproduction (so many well-known instances of which are given by Dr. Butter, John Hunter, and others), but that the garb of the cock is assumed by those hen birds which from malformation or disease are rendered unable to assist in the continuation of the species.

The following three modes by which changes in the appearance of the plumage of birds are produced have been pointed out by Yarrell:—1, By the feather itself becoming altered in colour. 2, By the bird's obtaining a certain portion of new feathers without shedding any of the old ones. 3, By an entire or partial moult, in which the old feathers are thrown off and new ones produced in their places. The first two of these changes are observed generally in the spring, indicating the approach of the breeding season; the third is usually partial in the spring, and entire in the autumn. The subjoined cut is explanatory of the situation of the principal parts of the plumage, particularly those most conducive to flight.



A A, Primaries; B B, tertials; C C, lesser coverts; D D, greater coverts; E E, bastard wing; F F, scapulars; G, upper tail-coverts; H, under tail-coverts; I, tail-feathers.

That the skin and integuments of birds perform the office of emunctory organs appears not only by their moulting, but also by the quantity of mealy dust separated from the skin in many birds. The cockatoo, for instance, discharges a quantity of white mealy dust from its skin, particularly at pairing time, according to Blumenbach; and Bruce, in the appendix to his 'Travels,' gives an account of his shooting a large bearded eagle, which, on his taking it in his hands, covered him with a powder which was yellow on the breast, where the feathers were of that colour, and brown on the back, where the plumage was of the same hue. A heron too which he shot is described as having a great quantity of blue powder on the breast and back.

The glands which secrete the oil used by birds in preening and dressing their plumage are situated on the upper part of the tail. Water-birds necessarily require a larger portion of this protecting fluid, and accordingly we find the glands largest in that race. Réaumur observes, that in that variety of the common fowl which has no tail (*Gallus ecaudatus*) these glands are absent.

Digestive Organs.

The bill has a horny covering which in some degree answers the purpose of teeth, and indeed it is in many instances notched so as to represent them. The form of this important organ varies greatly, but with evidence of the most perfect design in each varied instance, according to the nature of the necessary food. Thus in birds of prey it well executes the office of a dissecting-knife; in seed-eating birds it forms a pair of seed-crackers for extricating the kernel from the husk which envelops it; in the swallows and goatsuckers it is a fly-trap; in the swans, geese, and ducks it is a flattened strainer, well furnished with nerves in the inside for the detection of the food remaining after the water is strained by that particular operation which every one must have observed a common duck perform with its bill in muddy water. In the storks and herons we find it a fish-spear; and in the snipes and their allies it becomes a sensitive probe, admirably adapted for penetrating boggy ground, and giving notice of the presence of the latent worm or animacule. The food is transmitted from the bill through the œsophagus into the stomach, which is composed of three parts, namely, the crop, which is a dilatation of the œsophagus, and lies just before the breast-bone; the membranous stomach (ventricule succenturié of the French); and the gizzard. The first of these is furnished with many mucous and salivary glands; in the next (and the structure of this may be best observed in the gallinaceous birds) there are a number of glandular bodies which pour out a copious secretion to mingle with the food as it is ground down by the powerful gizzard, which reaches its highest development in graminivorous birds. This mill is rendered still more effective by the swallowing of small hard stones by those birds with their food, a practice which is clearly instinctive, and carried sometimes to a great extent. In the museum of the College of Surgeons (London) is a large glass bottle entirely filled with pebbles, &c. taken from the stomach of an ostrich. The well-known experiments of conveying bullets beset with needles and even lancets into the stomachs of graminivorous birds, with the effect of the total destruction of those sharp instruments in a short period, need only be referred to here; but as Felix Plater's observations have not attained quite so much celebrity we shall shortly mention them. He found that an onyx swallowed by a hen was diminished one-fourth in four days, and that a louis-d'or lost in this way sixteen grains of its weight.

In such birds as nourish their young from the crop the glands swell very much at the hatching season, and secrete a greater quantity of fluid than usual. In the pigeon, which thus feeds its young, there is a spherical bag formed on each side of the œsophagus, a specimen of which may be seen in the museum of the College of Surgeons. It is not improbable that the banter about 'pigeon's milk' took its rise from this part of the economy of the bird.

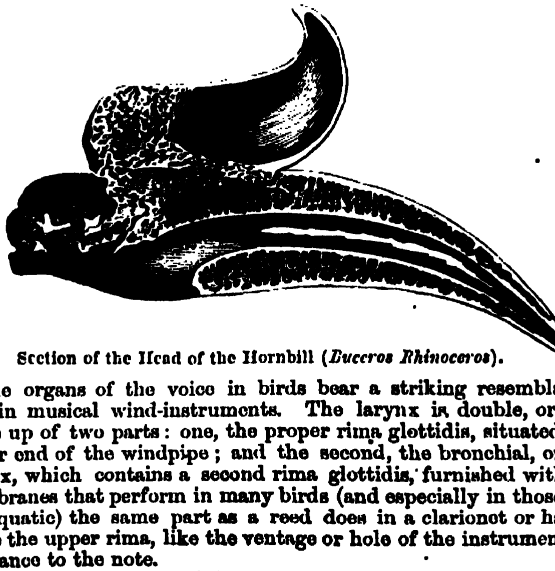
In those birds which feed on flesh, fish, or worms, and which consequently do not require so powerful an apparatus, the muscles of the gizzard are reduced to an extreme weakness, and that organ appears to make only a part of the same membranous bag with the ventricule succenturié.

The food being thus reduced into a sort of chyme passes through the remainder of the intestinal canal, where all the nutritious parts are taken into the system, and the remainder is at length expelled by the cloaca, where the urinary ducts terminate and the organs of generation are situated. It may be worth mentioning that the liver becomes much larger in domesticated birds than in wild ones (a propensity which can be increased by artificial means, as the gourmand who revels in his 'foies gras' well knows), and that the gall-bladder is entirely wanting in some birds, the parrot and pigeon for instance. Hence no doubt the saying, "He has no more gall than a pigeon." The pancreas (sweet-bread) is of considerable size in birds, but the spleen is small.

Organs of Circulation, Respiration, and Voice.

The heart in this class is of peculiar structure. Instead of the membranous valve which is present in both ventricles of the heart of mammifers, and in the left ventricle in birds, the right ventricle of the heart in the latter is furnished with a strong muscle which assists in driving the blood with greater impetuosity from the right side of the heart into the lungs; a structure rendered necessary from the want of expansion of the lungs in breathing consequent upon their connection with the numerous air-cells. The lungs are small and flattened, and adhere to the back of the chest in the intervals of the ribs, and a considerable part of the abdomen as well as of the chest is occupied by membranous air-cells with which the lungs communicate by considerable apertures. In addition to these, a great portion of the skeleton in most birds becomes a receptacle for air. Instead of marrow the larger cylindrical bones contain air, and form large tubes, interrupted only towards the ends by transverse bony fibres. The broad bones present internally a reticulated bony texture, pervaded by the same fluid, communicated from the lungs by small air-cells. The enormous bills of the toucan and of the hornbill are supplied with air from the same quarter.

The effect of this structure in lightening the body of the bird, and facilitating its motions whether in flying, swimming, or running, is obvious. Where the demand is greatest (as in birds of the highest and most rapid flight) the supply is largest. Thus, in the eagle, we find the bony cells of great size and very numerous. The section of a head of the Hornbill (*Buceros Rhinoceros*), here represented, will convey some idea of the structure of these air-cells.



Section of the Head of the Hornbill (*Buceros Rhinoceros*).

The organs of the voice in birds bear a striking resemblance to certain musical wind-instruments. The larynx is double, or rather made up of two parts: one, the proper rima glottidis, situated at the upper end of the windpipe; and the second, the bronchial, or lower larynx, which contains a second rima glottidis, furnished with tense membranes that perform in many birds (and especially in those which are aquatic) the same part as a reed does in a clarionet or hautboy, while the upper rima, like the ventage or hole of the instrument, gives utterance to the note.

The length of the windpipe and the structure of the lower larynx vary much in different species and even in the sexes, particularly among the water-birds. In the domestic or dumb swan the windpipe is straight; in the male wild swan the windpipe is convoluted in the hollow of the breast-bone, like the tube of a French horn.

The following are the conclusions of M. Jacquemin from his observations on the respiration of birds. After observing that the air enters not only into the lungs and about the parietes of the chest, but that it also penetrates by certain openings (foramina) into eight pneumatic bags or air-cells, occupying a considerable portion of the pectoro-abdominal cavity, and thence into the upper and lower extremities, he concludes:—1st, That the pneumatic bags are so situated as to be ready conductors of the air into the more solid parts of the body; and that the air, by surrounding the most weighty viscera, may support the bird in flight, and contribute to the facility of its motions when so employed. 2nd, That the quantity of air thus introduced penetrates the most internal recesses of their bodies, tending to dry the marrow in the bones and a portion of the fluids; a diminution of specific gravity is the result, the true cause of which has been, in his opinion, vainly sought in the quantity alone of permeating air. 3rd, That in birds the oxidation of the nourishing juices is not entirely effected in the lungs, but is much promoted also in the pneumatic bags above mentioned, for their contained air operates through the membranes upon the blood-vessels and lymphatics in contact with them; a more complete and speedy oxidation is the result. 4th, That not only the skeleton, but all the viscera are much more permeable by air in birds than in any of the other vertebrated animals. 5th, That the air-reservoirs are not always symmetrical, their shape and extent depending entirely upon the form and situation of the organs among which they occur; but the supply is so modified that the total quantity received into the pneumatic bags on the right side of the body is equal to that which enters into those on the left; and indeed without the maintenance of this condition the act of flying would be impossible, and that of walking difficult. 6th, That no portion of a bird's structure is impervious to air; it reaches even the last joints (phalanges) of the wings and feet, and the last caudal vertebræ, or rump-bones. The quill of the feathers is not excepted, as has been sometimes asserted. 7th, That the air within the head has a separate circulation, and does not directly communicate with the air-pipes of the rest of the body. 8th, That in no instance does the air come into direct contact with the viscera or nourishing juices, but invariably through the medium of a membrane, however fine and transparent. 9th, That the volume of air which birds can thus introduce into their bodies, and the force with which they can expel it, offer the only explanation how so small a creature as a singing-bird (the nightingale, for example) is able to utter notes so powerful, and without any apparent fatigue to warble so long and so musically.

The organs of respiration in birds, as well as their sexual organs, are, according to Purkinje and Valentin, supplied with cilia on their surface.

Brain, Nervous System, and Senses.

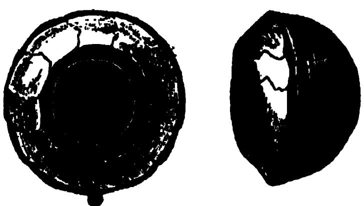
The brain of birds possesses the same characters which are to be found in other oviparous vertebrated animals, but its proportional volume is its distinguishing peculiarity; and this volume often surpasses the development of that organ in mammifers. Indeed, in some birds, and more particularly in some of the songsters, the brain has been said to exceed that of man when considered in reference to the size of the head and of the whole body. The following scale has been given as an example of the size of the brain in relation to that of the body:—Eagle, 1-260th of the body; sparrow, 1-25th; chaffinch, 1-27th; redbreast, 1-32nd; blackbird, 1-68th; canarybird, 1-14th; cock, 1-25th; duck, 1-257th; goose, 1-360th. In man the brain forms from 1-22nd to 1-33rd of the body; in some apes, 1-22nd; in the elephant, 1-500th; in the horse, 1-400th; in the dog, 1-161st; and in the cat, 1-94th.

The size of the brain in birds arises principally from tubercles analogous to the corpora striata of mammifers, and not from the hemispheres, which are small, smooth, and without convolutions. The cerebellum is large, almost without lateral lobes, and formed principally by the vermiform process. Several parts found in the brain of mammifers are absent in birds, and among these are the corpus callosum and pons Varolii.

Of the five senses, sight, smell, and hearing are most acute in birds.

Sight.—We have seen that the bony orbits are of great magnitude, and the organs of sight which are contained therein are proportionately large. In the birds of prey the orbits have the shape of a "chalice," says Blumenbach, "or cup used in the communion service. The cornea, which is very convex, forms the bottom of the cup, and the posterior segment of the sclerotica resembles its cover. This peculiar form arises from the curvature and length of the bony plates, which, as in all other birds, occupy the front of the sclerotica, lying close together and overlapping each other. These bony plates form in general a flat or slightly convex ring; being long and curved in the *Accipitres* (Hawks) they form a concave ring, which gives the whole eyeball the above-mentioned form." By means of this ring the eye becomes a kind of self-adjusting telescope, so as to take in both near and very distant objects.

A representation of the sclerotic plates, forming the bony ring in the eye of the Penguin (*Aptenodytes*), is here given. They remind us forcibly of the eye-plates in some of the reptiles, particularly of those belonging to the eyes of the Enaliosaurians, or fossil marine lizards. The penguin has to adjust its eye for vision both on land and under water. This contrivance must greatly assist the adjustment necessary for seeing clearly in such different media.



Sclerotic Plates of Penguin (*Aptenodytes*).

The crystalline humour is flat in birds; and the vitreous humour is very small. The colour of the iris varies in different species, and in many cases is very brilliant. The marsupium, which arises in the back of the eye, and the use of which is not very clearly ascertained, is a peculiarity in the eye of birds. They have three eye-lids, two of which, the upper and lower, are closed in most of the race by the elevation of the lower one, as may be frequently seen in our domestic poultry. The owl, the goat-sucker, and a few others, have the power of depressing the upper eye-lid. Of these birds the upper only is furnished with eye-lashes generally; the ostrich, secretary vulture, some parrots, and a few other birds, have them in both lids. But the third eye-lid, or nictitating membrane, forms the most curious apparatus. When at rest, this, which is a thin semi-transparent fold of the tunica conjunctiva, lies in the inner corner of the eye, with its loose edge nearly vertical. By the combined action of two muscles which are attached towards the back of the sclerotica, it is capable of being drawn out so as to cover the whole front of the eye-ball like a curtain, and its own elasticity restores it to the corner in which it rested. This, it is said, enables the eagle to look at the sun. The peculiar movements of this organ may be seen amongst the fine collection of eagles at the gardens of the Zoological Society in the Regent's Park.

Hearing.—This sense appears to be sufficiently acute in birds, though (with the exception of the night-birds, the owls in particular) they have no external cartilaginous ear; and the peculiar valve, partly muscular, partly membranous, placed at the auditory opening even in those birds, has none of the development which generally marks the concha of mammifers. The peculiar arrangement of the comparatively loosely barbed feathers, however, round the aperture (meatus auditorius) compensates for it; and this arrangement may be well seen in the rapacious birds. The membrane of the drum (membrana tympani) is convex externally, and the drums of both ears are connected by the air-cells of the skull. There is neither malleus nor stapes, and their place is supplied by a single auditory bone (ossiculum auditus) which connects the membranes of the drum with the fenestra ovalis. The Eustachian tubes terminate in a sort of common aperture on the concavity of the palate. The labyrinth is without a cochlea; instead of which there is a short, blunt, hollow bony process obliquely directed backwards from the vestibule, and divided into two portions, one of which ends at the fenestra rotunda.

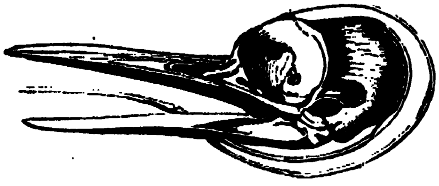
Smell.—This sense in the majority of birds seems to be highly developed. The olfactory nerve is given off from the foremost part of the front lobe of the brain, whence it passes along a canal to the nose, and is ramified on the pituitary membrane, which is spread over two or three pairs of bony or cartilaginous conchæ narium. The nostrils terminate in different parts of the upper mandible in different genera; and, according as these apertures are smaller or larger, or more or less covered by membranes, cartilages, feathers, or other integuments, the sense is probably more or less acute. But no bird is without nostrils, though Buffon asserts that several are unprovided with them: the puffin indeed and some others have them so small, and placed so closely on the margin of the mandible, that they are not easily detected.

This sense was supposed to have reached its highest point of perfection in the vultures and other carrion-birds. Poets and philosophers have dwelt on the 'delight' with which they—

> ". . . . . snuff'd the smell
> Of mortal change on earth . .
> Sagacious of the quarry from afar."

But, according to the experiments of Audubon (and they were made with a species which has obtained a reputation for great sagacity in this way), the nostrils do not seem to have been of the least assistance to the birds in directing them to their prey; while the eye, even when the birds were far above human sight, appears to have been infallible. This conclusion has been indeed disputed: but the facts stated by Audubon are very strong.

Taste.—Though all birds possess a tongue, it is probable that but few find enjoyment in the organ as ministering to their taste, and in those it is soft, thick, and covered with papillæ. Some of the birds of prey, some of the swimmers, and the parrots generally, have such a tongue, and there can be no doubt that these taste food of a soft or fluid nature, and select that which they like best. But in general the tongue is horny and stiff, and appears unsuited to convey such impressions, though as an organ for taking food it becomes of the highest importance. In the humming-birds and other honey-suckers it is a tubular pump, and in the woodpeckers it is an insect spear. In both cases it can be protruded and retracted at pleasure; and the simple but beautiful machinery by which this act of volition is performed is adapted with the most masterly fitness to the motion required. Upon examining the tongue of the common green woodpecker, we shall find that, instead of being very long, as it is erroneously supposed to be, it is really very short, sharp-pointed, and horny, with barbs at its sides. Behind this lies the singular tongue-bone (os hyoides), slender, and with two very long legs or appendages (crura). This is made up of five parts, consisting of a single portion and two pairs of cartilages. Let us suppose the tongue to be at rest, and then the single piece lies in a fleshy sheath, capable of great extension. To this piece the first pair of cartilages, which are situated at the sides of the neck, are joined, while the second pair, springing from these, run under the integuments completely over the skull, and, advancing forward, converge in a kind of groove, terminating generally in the right side of the upper jaw. This second pair, by their elasticity, become the springs which set the whole in motion. When the organ is to be protruded, the anterior pieces are drawn together, and enter the extended sheath of the single piece: the tongue is thus elongated as it were, and the bird can thrust it far forth.



Os Hyoides of Woodpecker.

Touch.—As applied to external objects this sense must be, generally speaking, very obtuse in birds. Feathers, horny beaks, and scaly skin, do not offer a satisfactory medium for conveying impressions by contact. But in those birds which search for their food in mud (ducks, for instance), where neither sight nor smell can be of much avail, the bill is covered with a skin abundantly supplied with sensation by nerves from all the three branches of the fifth pair, in order that they may successfully feel about for their hidden sustenance.

Reproduction and Migration.

The continuation of the species is carried on by eggs, which are laid in a nest more or less artificial according as the nestling is more or less capable of gathering its own food at the time of its exclusion from the egg. Of those birds whose young possess this capability in the highest degree, the male is for the most part polygamous, and does not pair; but among those whose young depend for some time on the parents for their sustenance, one male confines his attentions to one female, as long at least as the seasons of love, incubation, and parental anxiety endure. To the first and second of these seasons we, in great measure, owe that outpouring of melody which renders our groves and gardens so musical in spring.

"There is every reason," writes Montagu, "to believe it is necessary there should be native notes peculiar to each species, or the sexes might have some difficulty in discovering each other, the species be intermixed, and a variety of mules produced; for we cannot suppose birds discriminate colours by which they know their species, because some distinct species are so exactly alike that a mixture might take place. The males of song-birds, and many others, do not in general search for the female; but, on the contrary, their business in the spring is to perch on some conspicuous spot, breathing out their full and amorous notes, which by instinct the female knows, and repairs to the spot to choose her mate. This is particularly verified with respect to the summer birds of passage. The nightingale and most of its genus, although timid and shy to a great degree, mount aloft to pour forth their amorous strains incessantly, each seemingly vieing in their love-laboured song before the females arrive. No sooner do they make their appearance than dreadful battles ensue, and their notes are considerably changed; sometimes their song is hurried through without the usual grace and elegance, at other times modulated into a soothing melody. The first we conceive to be a provocation to battle on the sight of another male; the last an amorous cadence, a courting address. This variety of song lasts no longer than till the female is fixed in her choice, which is in general in a few days after her arrival; and if the season is favourable she soon begins the task allotted to her sex."

We entirely agree with the writer of this animated passage that "'Tis love creates their melody," and that the ear is a principal guide to the hen-bird in her choice of a mate; but we cannot entirely exclude the eye when we remember what pains have been taken in most instances to distinguish the sexes by the colour of their feathered garb, and even in many instances to prepare a nuptial dress ('plumage de nôces' of the French) for the male, which fades when the season of

We must not dwell here upon the wonders of birds'-nests, their admirable structure as places of comfort and concealment, and the exquisite workmanship of some of them—that of the goldfinch, for instance. In those snug receptacles the eggs are deposited and hatched. Then the old birds feel all the parent within them, and entirely forget their own safety and wants in protecting and providing for their helpless nestlings. This parental love changes the timid at once to the brave; for birds of prey, cats, dogs, and sometimes even man, when he approaches the sanctuary, are attacked and followed with angry cries. For some time after quitting the nest this care continues, till the nestling is able to provide for itself. Then the whole scene changes. The young bird still lingers about the old one, and approaches it when it finds a worm or insect, expectant of the morsel. At first the young bird is unheeded and treated coldly; but if it does not take this hint, and perseveres in its solicitations, the parent, which but a few days before would have braved a hawk or a cat in its defence, and would have been content to suffer hunger rather than have seen it without food, gives it a buffet, and thus compels it to rely on its own resources.

Few phenomena have attracted more attention than the migration of birds. That some of our delicate songsters, with no great power of wing, should cross the seas periodically, returning, as they undoubtedly do, to those spots which they have before haunted, and which are associated in their memories with the pleasing cares of former years, excites our admiration, if not our astonishment. As regularly as the seasons, of which many of them are the harbingers, do these little travellers visit us, and as regularly do they take their departure. The immediate cause of migration is no doubt to be found in temperature and food, particularly that which is adapted for the sustenance of the young; and the instinct of the bird accordingly leads it from one climate to another.

Systematic Arrangement and Natural History.

Birds appear to have been objects of interest from the earliest periods. In comparatively later times we find them mingling in the superstitions of Greece and Rome; and it is evident that their history and habits were familiar not only to the husbandman and the augur, but to the great mass of the people. Without such a familiarity on the part of the Athenians, Aristophanes would hardly have ventured on introducing his audience to Νεφελακοκκυγία (see his play entitled 'Ὄρνιθες,' 'The Birds'); nor would other poets, Grecian and Roman, so often have referred to these animals as well-known harbingers of certain times and seasons. But it remained for Aristotle, and after him Pliny, to take up the subject philosophically. The former, in his 'History of Animals,' has distinguished the species, and recorded the habits of birds with the accuracy and power which distinguished that great observer; the latter, in the tenth book of his 'Natural History' has displayed much learning but not a great deal of originality.

In modern literature the first writer of note on this subject is Pierre Belon, who in 1555 arranged these animals according to their habits and their haunts. In his system the rapacious birds form the first division, the waders the second, the swimmers the third, and the birds which nestle in trees or on the ground, the fourth. He was an able zoologist and accurate observer, and has pointed out the comparative anatomy of birds with reference to that of man especially.

The third part of Conrad Gesner's 'History of Animals,' published in 1555, consists of his treatise on birds, where he has with some labour collected their various national names, and referred to the writers who had noticed the subject.

In 1599 Aldrovandus of Bologna published his 'Ornithology.' Pursuing the plan of Belon, he arranged the birds according to their haunts and their food, adding many new descriptions.

These three works are all illustrated with woodcuts.

In 1657 Johnston published his 'Natural History,' a kind of 'Repertorium Zoologicum,' wherein all that had been done before his time was condensed, and where every monstrous zoological fable was perpetuated, even in the copper-plates, which ministered to the appetites of those who loved to see what mermen and mermaids were like, and delighted in the sight of "hydras and chimeras dire."

We now approach a period wherein the reign of System commenced; and we owe one of the first natural arrangements, if not the first, to Francis Willughby, an English gentleman, whose 'System of Ornithology' was edited by our celebrated countryman Ray in 1678, after the author's death. It is a work of very great merit. The general divisions are two, 'Land-Birds,' and 'Water-Birds.' The land-birds are further divided into those which have a crooked beak and crooked talons, and those which have those parts nearly straight.

The water-birds are arranged in three sections. The first consists of waders, and those which haunt watery places; the second of those that are of a "middle nature, between swimmers and waders, or rather that partake of both kinds, some whereof are cloven-footed and yet swim; others whole-footed, but yet very long-legged, like the waders;" the third is formed by the palmated birds, or swimmers.

The same friendly office that was performed for Willughby by Ray, Dr. Derham executed for the latter, whose 'Synopsis Methodica Avium,' a posthumous work, but entirely completed by the author before his death, was published by the Doctor in 1713. In this Synopsis Ray carried out and further improved Willughby's system. Upon the works of these English naturalists rested in great measure the zoological system of Linnæus.

The first sketch of the Swedish naturalist's 'Systema Naturæ' appeared in folio, at Leyden, in 1735. It consisted of twelve pages, and was, as Linnæus himself says, "Conspectus tantum operis et quasi mappa geographica." Eight subsequent editions, in various forms, with gradually increasing information, were published in various places, and in 1758 the ninth edition ("longè auctius factum a me ipso," says the author) was sent forth in 8vo. In this edition the birds are arranged under the same 'orders' as they are in the twelfth and last edition, which appeared in 1766. The thirteenth edition was not the author's, but Gmelin's.

The following are the orders of Linnæus's class *Aves*:—

1. *Accipitres.* Birds of Prey, properly so called.
2. *Picæ.* Woodpeckers, Crows, Humming-Birds, Kingfishers, &c. &c. &c.
3. *Anseres.* Swimmers.
4. *Grallæ.* Waders.
5. *Gallinæ.* Gallinaceous Birds (Partridge and Domestic Fowl, for instance).
6. *Passeres.* Sparrows, Finches, Thrushes, Doves, Swallows, &c. &c.

These orders, some of which are not very natural, include with their subdivisions 78 genera.

In 1760 appeared the system of Brisson, which divides birds into two great sections. The first, consisting of those whose toes are deprived of membranes; the second, of those whose toes are furnished with membranes through their whole length.

There are many subdivisions, under which are arranged 26 orders, including 115 genera. This able ornithologist owes much of his celebrity to the minute accuracy of his specific descriptions.

In 1770 Buffon published the first part of his work relating to birds. It is marked by the same eloquent animated style which adorns the rest of his 'Natural History;' but much cannot be said for its arrangement, nor for the justice of some of its conclusions.

Schæffer, in his 'Elementa Ornithologica,' which was given to the public in 1744, divides birds into two great families, *Nudipedes* and *Palmipedes.*

Scopoli (1777), in his 'Introduction to Natural History,' divides them also into two families; but he takes his distinction from the arrangement of the scaly skin on the legs; the first division or *Retipedes* consisting of those the skin of whose legs is marked by small polygonal scales; the second, *Scutipedes,* of those the front of whose legs is covered with segments or unequal rings with lateral longitudinal furrows.

In 1781 our countryman Latham published his general synopsis, and in 1787 and in 1801 his two supplements appeared. In 1790 his 'Index Ornithologicus,' in two volumes quarto, being an abridgment of his more extended work, was given to the public. Separating, like Willughby and Ray, the birds into two grand divisions, land-birds and water-birds, he arranges them under the following orders, which include 101 genera:—

Land-Birds.	Water-Birds.
1. *Accipitres.*	7. *Grallæ.*
2. *Picæ.*	8. *Pinnatipedes.*
3. *Passeres.*	9. *Palmipedes.*
4. *Columbæ.*	
5. *Gallinæ,*	
6. *Struthiones.*	

In 1799 M. de Lacépède published his method, arranging 130 genera under 39 orders.

In 1806 Duméril, in his 'Zoologie Analytique,' divided birds into six orders.

The following is Blumenbach's arrangement:—

Land-Birds.	Water-Birds.
1. *Accipitres.*	8. *Grallæ.*
2. *Levirostres.*	9. *Anseres.*
3. *Pici.*	
4. *Coraces.*	
5. *Passeres.*	
6. *Gallinæ.*	
7. *Struthiones.*	

In 1810 Meyer, in the 'Almanach des Oiseaux de l'Allemagne, par Messrs. Meyer et Wolff,' arranged them under 11 orders.

In 1811 Illiger divided them into seven orders, including 41 families.

Then came Cuvier, who in his 'Règne Animal' (1817) published the following method:—

1. *Accipitres.*
2. *Passeres.*
3. *Scansores* (Climbers).
4. *Gallinæ.*
5. *Grallæ.*
6. *Palmipedes.*

Vieillot, whose work is dated in 1816, though it did not appear till 1817, distributes birds into the following five orders:—

1. *Accipitres.*
2. *Sylvicolæ.*
3. *Gallinacei.*
4. *Grallatores.*
5. *Natatores.*

Temminck's arrangement (1815-20) consists of the following 16 orders:—

1. *Rapaces.*
2. *Omnivores.*
3. *Insectivores.*
4. *Granivores.*
5. *Zygodactyles.*
6. *Anisodactyles.*
7. *Alcyons.*
8. *Chelidons.*
9. *Pigeons.*
10. *Gallinacés.*
11. *Alectorides*
12. *Coureurs.*
13. *Gralles.*
14. *Pinnatipèdes.*
15. *Palmipèdes.*
16. *Inertes.*

In 1825 Nicholas Aylward Vigors (following out the principle adopted by William Sharp M'Leay, in his 'Horæ Entomologicæ,' a work of great learning and deep reasoning) proposed his arrangement of birds according to their natural affinities. "I discovered," says the author in his paper in the 14th volume of the 'Transactions of the Linnæan Society,' "as I advanced, that the larger or primary groups were connected by an uninterrupted chain of affinities; that this series or chain returned into itself; and that the groups of which it was composed preserved in their regular succession an analogy to the corresponding groups or orders of the contiguous classes of zoology. I equally detected the existence of the same principle in most of the subordinate subdivisions, even down to the minutest, to a degree at least sufficiently extensive to afford grounds for asserting its general prevalence."

Thus, if his five orders,

Insessores,
Raptores, AVES. *Rasores,*
Natatores, *Grallatores,*

be arranged round a common centre, the author conceives that they would be found to be mutually connected together, and that the plan which holds good in the general division will be found to be confirmed on examining the subdivisions.

The second order *Insessores,* for instance, he divides into five tribes:—

Conirostres,
Dentirostres, INSESSORES. *Scansores,*
Fissirostres, *Tenuirostres,*

in which he finds a similar connection, as he also does in the five families into which he further separates each tribe.

In the same year M. Latreille published his method as follows:—

Section 1, Les Terrestres.	Section 2, Les Aquatiques.
1. Rapaces.	6. Echassiers.
2. Passereaux.	7. Palmipèdes.
3. Grimpeurs.	
4. Passerigalles.	
5. Gallinacés.	

These orders include 252 genera.

The method proposed by M. de Blainville in 1815, 1821, and 1822, and developed by his pupil, M. Lherminier, in 1827, is founded entirely on anatomical details, and principally upon the comparative development of the sternum.

In 1828 M. Lesson published his 'Projet,' wherein he commences with the two great divisions 'Terrestrial' and 'Aquatic,' and distributes the birds into nine orders, founded on the form of the toes, wings, and beak. The ninth order consists of 'Paradoxaux,' to which he refers the Ornithorhynchus.

In 1831, Mr. Swainson, rejecting the quinarian theory above alluded to, which he had adopted in the year 1824, proposed (in the second part of the 'Fauna Boreali-Americana' containing the birds) a new arrangement, which he framed according to the dogma that "the primary divisions of every natural group, of whatever extent or value, are three, each of which forms its own circle."

No one can read over the preceding compendium, which only embraces the more prominent systems, without perceiving that the great aim of modern science has been to produce the best natural arrangement. No sooner has one method been advanced and considered, than doubts have arisen, and another and another still succeeds. Cuvier expressed his dissent from all the systems which he had seen; and it is no doubt as true now as when he expressed his conviction that the true arrangement is yet to be sought for.

To give a list of all the writers on the Natural History of Birds would be quite out of place in a work of this description; we must therefore conclude this article with the following enumeration of some of the most celebrated authors in this department.

The ornithology of America and the West Indies has been given by Hernandez, Marcgrave, De Azara, Sloane, Catesby, Vieillot, Wilson, Spix, C. L. Bonaparte (Prince of Canino), Audubon, Richardson, Swainson, and Nuttall.

That of Britain by Pennant, Lewin, White, Bewick, Montagu, Donovan, Selby, Mudie, Yarrell, Macgillivray, W. Thompson, Meyer, and others.

That of Europe by Temminck; that of Germany by Meyer and Wolff; and C. L. Bonaparte that of Italy. Gould's 'Birds of Europe' illustrate the ornithology of the Continent and British Islands. His other works on the Birds of Australia, the Humming-Birds, the Toucans, and various monographs, are amongst the most splendid contributions to the science of Natural History.

Le Vaillant has illustrated the birds of Africa and other countries.

The following names of some of those who have also distinguished themselves as general authors or particular illustrators will readily occur to the student who enters upon this branch of Natural History:—Albin, Audebert, Audubon, Barraband, Bechstein, Bennett, Blyth, Brisson, Brunnich, Buffon, Buhle, Cuvier, Daudin, Desmarest, Edwards, Fleming, Foster, Frisch, Gerardin, Gould, Gray, Gunther, Hardwicke, Herbert, Houttuyn, Hunter, Illiger, Jardine, Jenner, Leach, Lear, Lesson, Macartney, M'Leay, Markwick, Meyer, Naumann, Nilsson, Nozeman, Rennie, Rüppell, Sabine, Savigny, Selby, Sepp, Schæffer, Shaw, Sheppard, Slaney, Sonnini, Spix, Stephens, H. E. Strickland, Swainson, Sweet, Syme, Vieillot, Vigors, Wagler, Waterton, Whitear, N. Wood, Yarrell.

Fossil Birds.

Although the remains of birds in a fossilised condition are not numerous, yet recent discoveries have given an interest to them not less than to that of any other class of animals. Sir Charles Lyell, in his 'Principles of Geology,' says that "the imbedding of the remains of birds in new strata must be of very rare occurrence, for their powers of flight insure them against perishing by numerous casualties to which quadrupeds are exposed during floods; and if they chance to be drowned, or to die when swimming on the water, it will scarcely ever happen that they will be submerged so as to become preserved in sedimentary deposits. In consequence of the hollow tubular structure of their bones, and the quantity of their feathers, they are extremely light in proportion to their volume, so that when first killed they do not sink to the bottom like quadrupeds, but float on the surface until the carcass either rots away or is devoured by predaceous animals." Nevertheless remains of birds have been found.

The earliest indications of the existence of birds are certain foot-tracks discovered by Professor Hitchcock, of Amherst, in the Triassic or New Red Argillaceous Sandstones of the valley of the Connecticut River. These foot-prints occur in considerable numbers in the district mentioned, and have been described by geologists under the name of *Ornithicnites*. A slab on which these remarkable markings are to be seen is in the collection of the British Museum. They evidently belong to birds of a large size, but unfortunately none of the remains of the creatures to which they belong have yet been discovered. Sir Charles Lyell has recently examined the district in which these impressions occur, and agrees with Professor Hitchcock in regarding them as the production of the feet of birds.

Some remains found by Dr. Mantell in the Wealden Strata of Tilgate Forest, were supposed by Baron Cuvier and Professor Owen to belong to a species of wading bird, but subsequent investigations have shown that these specimens were portions of the skeleton of a species of Pterodactyl. A microscopic examination however by Mr. Bowerbank and Professor Quekett of specimens since discovered by Dr. Mantell, has led these gentlemen to conclude that they belong to birds, leading to the inference that these animals did exist at the period of the deposit of the Wealden Beds.

In the 'British Fossil Mammals and Birds' Professor Owen has described the remains of a gigantic bird obtained by the Earl of Enniskillen from the Chalk near Maidstone. The portion described is regarded by Professor Owen as the shaft of the humerus, and he concludes that it belonged to a bird closely allied to the Albatross of the present day. He has named it *Cimoliornis Diomedeus*.

As we approach nearer the historic period of the earth's surface, the remains of the bones of birds become more decisive and more numerous. In most of the ancient Tertiary Strata remains of several genera of birds occur. In the Sevalik hills of India they are associated with the remains of several species of proboscidiform animals. In the basin of Paris they have been found in conjunction with the bones of the *Palæotherium*, &c. In the Tertiary deposits of Auvergne they have also been found, and the ossiferous caverns of the continent of Europe and of Great Britain have presented the bones of numerous species of animals now living, with here and there an extinct species. These remains however have been sufficiently scarce to be greatly prized by the collectors of fossils.

In the year 1839 Professor Owen received from Mr. Rule a specimen of the femur of a gigantic bird, allied to the ostrich and other struthious birds now in existence. To the bird to which this bone belonged Professor Owen gave the name of *Dinornis*. [Dinornis.] This specimen was obtained from New Zealand, and was quickly followed by a large collection of the bones of other extinct birds, made by Mr. Walter Mantell of Wellington, son of the late Dr. Gideon Mantell. In this collection, not only were there the bones of *Dinornis*, confirming all the anticipations which had been formed by Professor Owen of this gigantic bird, but also the remains of several other species of *Dinornis*, and other genera. The character of some of these remains, and their having been found in fire-heaps in conjunction with human bones, and allusions in the traditions and songs of the natives, lead to the undoubted conclusion that within the historic period the *Dinornis*, under the name of 'Moa,' was known to the Maoris, the native inhabitants of New Zealand. Amongst the remains is that of a genus called *Notornis*; and during his excursions into the interior for the purpose of ascertaining if any of these birds still existed, Mr. W. Mantell had the good fortune to capture a living specimen. [Notornis.] This bird has been described and figured by Mr. Gould in his 'Birds of Australia,' and an engraving is also given by the late Dr. Mantell in his popular work descriptive of the organic remains of the British Museum, entitled 'Petrifactions and their Teachings.'

From these facts we are led to conclude that long before New Zealand was inhabited by man it was densely peopled by colossal struthious birds, of which the *Apteryx* [Apteryx], *Brachypteryx* [Brachypteryx], and *Notornis* are but the degenerate representatives. It is probable also that New Zealand, together with Chatham Island, Norfolk Island, and others, are but the mountain-tops of a continent, which was probably covered with these creatures, presenting a remarkable feature in the history of the earth's surface, and affording interesting matter for speculation with regard to the progression of organised life upon the globe.

The history of the New Zealand birds is also one of special interest in connection with a group of birds, some of which also, as the *Dodo* and *Solitaire* [Dodo], have existed within the historic period, but are now no longer to be found, and which had their principal seat of existence in the Mauritius.

(Ansted, *Geology*; Owen, *British Fossil Mammals and Birds*; Owen, *Transactions of the Zoological Society*, 1839, 1844, 1846, 1848, 1850; Colenso, *Annals of Natural History*; Mantell, *Petrifactions and their Teachings*; Strickland and Melville, *The Dodo and its Kindred*.)

BIRDS' NESTS, EDIBLE. [Algæ.]

BIRDS OF PARADISE. With no family of birds has fiction been more busy than with the Birds of Paradise. From one fabulist to another came the tradition (losing nothing, as is usual with traditions, in its descent), that these "gay creatures of the element" passed their whole existence in sailing in the air, where all the functions of life were carried on, even to the production of their eggs and young. The dew and the vapours were said to be their only food, nor were they ever supposed to touch the earth till the moment of their death, never taking rest except by suspending themselves from the branches of trees by the shafts of the two elongated feathers which form a characteristic of this beautiful race. The appellations of Lufft-Vogel, Paradyss-Vogel, Passaros de Sol, Birds of Paradise, and God's Birds (to say nothing of Phœnix, a name which was applied to one of them), kept up the delusion that originated in the craft of the inhabitants of the eastern countries where they are found; for the natives scarcely ever produced a skin in former times from which they had not carefully extirpated the feet. Nor was it only the extreme elegance and richness of their feathers that caused these birds to be sought as the plume for the turbans of oriental chiefs; for he who wore that plume, relying implicitly on the romantic accounts of the life and habits of the bird, and impressed with its sacred names, believed that he bore a charmed life, and that he should be invulnerable even where the fight raged most furiously.

In vain did honest Pigafetta, who is supposed to have been the first who introduced these birds to the notice of Europeans, represent them as being furnished with legs; in vain was the same truth attested by Marcgrave, John de Laet, Clusius, Wormius, and Bontius (the last of whom observes on their crooked claws, and even asserts that they devour little birds, such as greenfinches), and referred to by Hernandez. A fairy tale was not to be so put down. Aldrovandus himself was deceived by the birds brought over in the mutilated state above described, and joined in the cry against poor Pigafetta, charging him with falsehood. Johnston, in 1657, writes thus oracularly of the Birds of Paradise:—" It is peculiar to them all to be without feet (although Aristotle asserts that no bird is without feet, and Pigafetta assigns to them feet a hand breadth in length);" and this he declares after Clusius had refuted the absurdity, and had stated that they had been brought to Holland (where Johnston's book was printed) with their feet on; and after the publication of Tradescant's Catalogue, wherein are mentioned among the 'whole birds' of his museum "Birds of Paradise, or Manucodiata, whereof are divers sorts, some with, some without leggs." And yet this same Johnston has no mercy on that part of the fable which asserts that they live on dew, are perpetually flying, and that their eggs are hatched in a natural cavity on the back of the male. "Of a verity," says the sage, "they must necessarily require rest, and are with ease suspended to the branches of trees by those threads in their tails."

Willughby and Ray treat these nonsensical stories as they deserve, and as was to be expected from their reputation as observers.

The high value set upon these birds awakened the cupidity and the fraud of the Chinese, who made up from parrots, parakeets, and others, artificial Birds of Paradise, so clumsily however that it is difficult to suppose that Seba, who figures three of them in the 60th plate of his first volume, could have been taken in by the manifest imposition. But there is nothing in the text to show that his suspicion was even excited; and this is the more extraordinary, as he figures two of the real species (plate 38 and plate 63) with sufficient accuracy.

Linnæus, who has commemorated the fable of the want of feet in these birds by bestowing upon the species most extensively known the name of 'apoda,' because, as he observes, "the older naturalists called it footless," says that the food of this species consists of the largest butterflies.

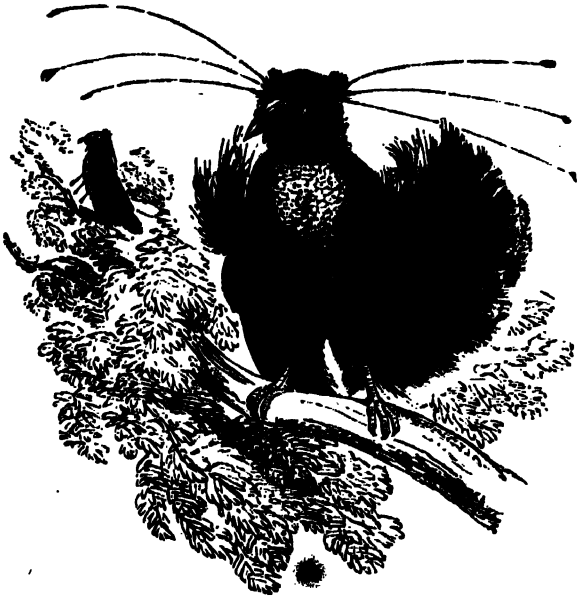
In the last edition of the 'Systema Naturæ' Linnæus gives but two species of the Birds of Paradise, to which he applies the generic name, *Paradisea*. These two species are *Paradisea apoda* and *Paradisea regia*. In Gmelin's edition the number of species is increased to eight, but one of them is the Paradise-Grakle.

Ornithologists seem to agree in placing these birds either among the Crows (*Corvidæ*) or in their immediate neighbourhood; and this, from the form of their beak and legs, and from their habits, to which we shall presently allude, appears to be their proper place.

Vieillot has divided the Linnæan genus *Paradisea* into the following genera:—

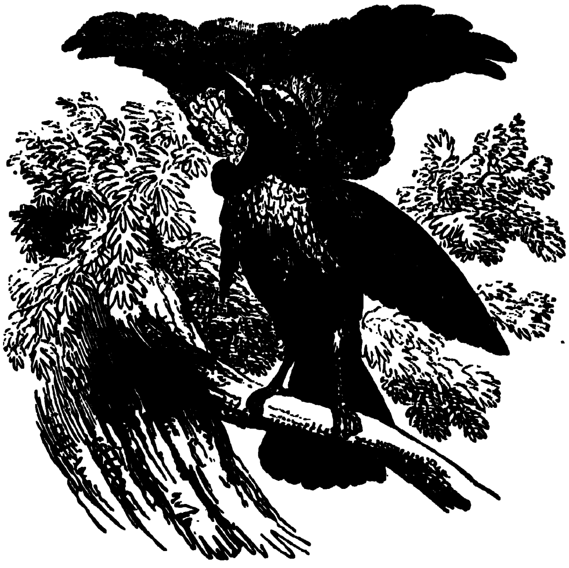
Parotia.—Beak furnished with short feathers to just beyond the middle, slender, compressed laterally, notched and curved at the tip; hypochondrial plumes long, broad, and loose.

Of this genus, *Parotia sexsetacea* (*Paradisea aurea* of Gmelin, *Paradisea sexsetacea* of Latham, the Sifilet of Buffon) is an example. The figure represents a male.



The Sifilet (*Parotia sexsetacea*).

Lophorina.—Beak furnished with elongated feathers to just beyond the middle, narrow above, slender, straight, notched, and bent at the tip; feathers of the neck long and disposed in a wing-form. Of this genus, *Lophorina superba* (*Paradisea superba* of Latham, Le Superbe of Buffon) is an example.



The Superb (*Lophorina superba*).

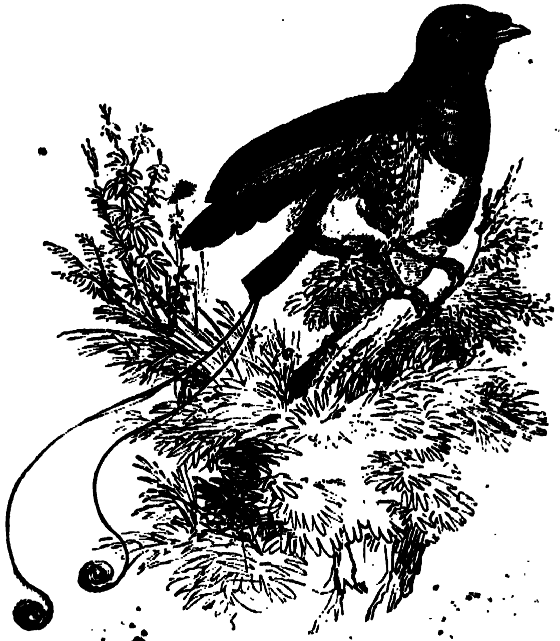
Cincinnurus.—Beak furnished at the base with small feathers directed forwards, slender, convex above, a little compressed at the sides, finely jagged and bent towards the tip; hypochondrial feathers broad, elongated, and truncated.

Of this genus, *Cincinnurus regius* (*Paradisea regia* of Linnæus, King-Bird of Paradise of Petiver, who has this note—" Brought from the Molucca Islands, and rarely to be seen here but in the cabinets of the most curious, as with Dr. Sloan, and in the repository of the Royal Society"—and Le Manucode of Buffon) is given as an example. The figure represents a male.

Samalia.—Beak robust, convex above, furnished at the base with velvet feathers, straight, compressed laterally, jagged towards the tip; hypochondrial feathers very long, flexible, decomposed, or cervical plumes moderate and stiff. Of this there are two sections, the type being *Paradisea magnifica* of Latham (Le Magnifique of Buffon).

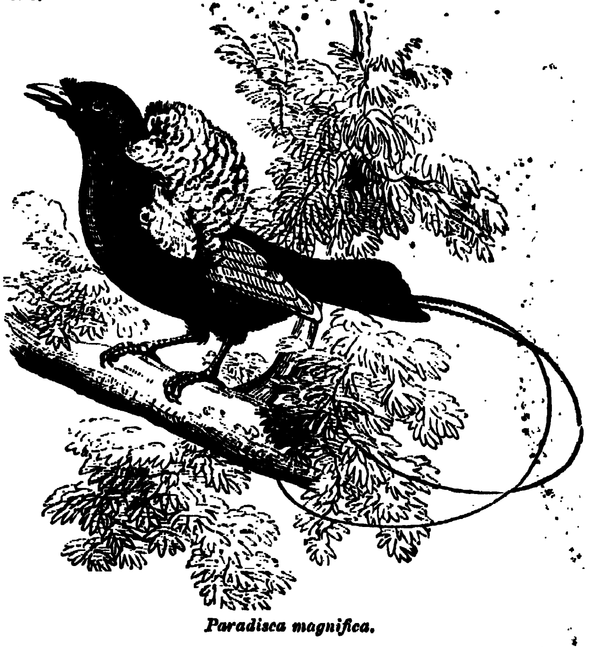
But perhaps the most elegant of all these birds is that which is best known and most often seen, the Great Emerald, Le grand Émeraude of the French (*Paradisea apoda* of Linnæus).

The cuts, which are taken from Levaillant, may convey some very faint idea of the forms of these birds, whose beauty beggars all description. Even the magnificent works of Levaillant and Vieillot, splendid as they are, cannot represent the vivid and changing tints of the originals, though the former had the advantage of the pencil of Barraband, whose drawings have all the life and truth of portraits. To these works, and such as these, and to our museums, those who wish to have a distinct notion of what nature can produce in form and brilliancy of plumage must repair. They are all inhabitants of New Guinea.



King-Bird of Paradise (*Cincinnurus regius*).

One of the best accounts we have of the living habits of these birds is given by M. Lesson, who, though he deeply laments his short stay at New Guinea (only 13 days), appears to have made the best use of his time.



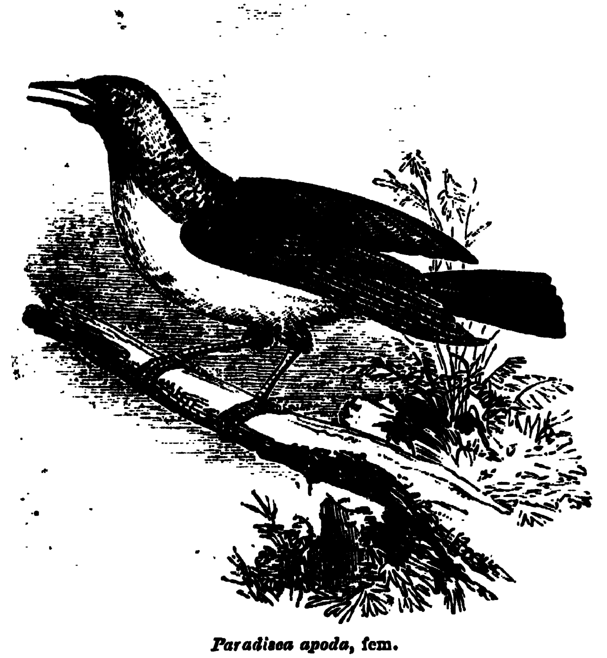
Paradisca magnifica.

" The Birds of Paradise," says M. Lesson, " or at least the Emerald (*Paradisea apoda*, Linn.), the only species concerning which we possess authentic intelligence, live in troops in the vast forests of the country of the Papuans, a group of islands situated under the equator, and which is composed of the islands Arou, Wagiou, and the great island called New Guinea. They are birds of passage, changing their quarters according to the monsoons. The females congregate in troops, assemble upon the tops of the highest trees in the forests, and all cry together to call the males. These last are always alone in the midst of some fifteen females, which compose their seraglio, after the manner of the gallinaceous birds."

M. Lesson then gives the following extract from his journal, written on the spot. After observing that the Birds of Paradise, with the exception of two species, were brought to the corvette, La-Coquille, by the Papuans, and that the quantity afforded reason for supposing that these birds, so esteemed in Europe, were singularly multiplied in those countries, he thus continues:—

"The Manucode * presented itself twice in our shooting excursions, and we killed the male and female. This species would seem to be monogamous, or perhaps it is only separated into pairs at the period of laying. In the woods this bird has no brilliancy; its fine-coloured plumage is not discovered, and the tints of the female are dull. It loves to take its station on the teak-trees (Arbres de Teck), whose ample foliage shelters it, and whose small fruit forms its nourishment.

The Great Emerald (*Paradisea apoda*), mas.



Paradisea apoda, fem.

Its irides are brown, and the feet are of a delicate azure. The Papuans call it Saya.

"Soon after our arrival on this land of promise (New Guinea) for the naturalist, I was on a shooting excursion. Scarcely had I walked some hundred paces in those ancient forests, the daughters of time, whose sombre depth was perhaps the most magnificent and stately sight that I had ever seen, when a Bird of Paradise struck my view: it flew gracefully and in undulations; the feathers of its sides formed an elegant and aërial plume, which without exaggeration bore no remote resemblance to a brilliant meteor. Surprised, astounded, enjoying an inexpressible gratification, I devoured this splendid bird with my eyes; but my emotion was so great that I forgot to shoot at it, and did not recollect that I had a gun in my hand till it was far away.

"One can scarcely have a just idea of the Paradise-Birds from the skins which the Papuans sell to the Malays, and which come to us in Europe. These people formerly hunted the birds to decorate the turbans of their chiefs. They call them Mambéfore in their tongue, and kill them during the night by climbing the trees where they perch, and shooting them with arrows made for the purpose, and very short, which they make with the stem (rachis) of the leaves of a palm (latanier). The campongs or villages of Mappia and of Emberbakène are celebrated for the quantity of birds which they prepare, and all the art of their inhabitants is directed to taking off the feet, skinning, thrusting a little stick through the body, and drying it in the smoke. Some more adroit, at the solicitation of the Chinese merchants, dry them with their feet on. The price of a Bird of Paradise among the Papuans of the coast is a piastre at least. We killed, during our stay at New Guinea, a score of these birds, which I prepared for the most part. . . . . .

"The Emerald when alive is of the size of a common jay, its beak and its feet are bluish; the irides are of a brilliant yellow; its motions are lively and agile; and in general it never perches except upon the summit of the most lofty trees. When it descends, it is for the purpose of eating the fruits of the lesser trees, or when the sun in full power compels it to seek the shade. It has a fancy for certain trees, and makes the neighbourhood re-echo with its piercing voice. The cry became fatal, because it indicated to us the movements of the bird. We were on the watch for it, and it was thus that we came to kill these birds; for when a male Bird of Paradise has perched, and hears a rustling in the silence of the forest, he is silent, and does not move. His call is 'voiko, voiko, voiko, voiko,' strongly articulated. The cry of the female is the same, but she raises it much more feebly. The latter, deprived of the brilliant plumage of the male, is clad in sombre attire. We met with them, assembled in scores, on every tree, while the males, always solitary, appeared but rarely.

"It is at the rising and setting of the sun that the Bird of Paradise goes to seek its food. In the middle of the day it remains hidden under the ample foliage of the teak-tree, and comes not forth. He seems to dread the scorching rays of the sun, and to be unwilling to expose himself to the attacks of a rival. . . . .

"In order to shoot Birds of Paradise, travellers who visit New Guinea should remember that it is necessary to leave the ship early in the morning, to arrive at the foot of a teak-tree or fig-tree, which these birds frequent for the sake of their fruit—(our stay was from the 26th of July to the 9th of August)—before half-past four, and to remain motionless till some of the males, urged by hunger, light upon the branches within range. It is indispensably requisite to have a gun which will carry very far with effect, and that the grains of shot should be large; for it is very difficult to kill an Emerald outright, and if he be only wounded it is very seldom that he is not lost in thickets so dense that there is no finding the way without a compass.

"The little Emerald Paradise-Bird feeds, without doubt, on many substances, in a state of liberty. I can affirm that it lives on the seeds of the teak-tree, and on a fruit called Amihou, of a rosy white, insipid and mucilaginous, of the size of a small European fig, and which belongs to a tree of the genus *Ficus*."

M. Lesson then goes on to state that he saw two Birds of Paradise which had been kept in a cage for more than six months by the principal Chinese merchant at Amboyna. They were always in motion, and were fed with boiled rice, but they had a special fondness for Cockroaches (*Blattæ*).

Bennett, in his 'Wanderings,' gives the following account of a Bird of Paradise (*Paradisea apoda*) which he found in Mr. Beale's aviary at Macao, where it had been confined nine years, exhibiting no appearance of age:—

"This elegant creature has a light, playful, and graceful manner, with an arch and impudent look; dances about when a visitor approaches the cage, and seems delighted at being made an object of admiration; its notes are very peculiar, resembling the cawing of the raven, but its tones are by far more varied. During four months of the year, from May to August, it moults. It washes itself regularly twice daily, and after having performed its ablutions throws its delicate feathers up nearly over the head, the quills of which feathers have a peculiar structure, so as to enable the bird to effect this object. Its food during confinement is boiled rice, mixed up with soft egg, together with plantains, and living insects of the grasshopper tribe;

---

* *Cincinnurus regius*, Vieillot. *Manucodiata* or *Manucodewata* is an appellation common to all the Birds of Paradise, and is said to signify at the Moluccas 'The Bird of God.'

these insects when thrown to him the bird contrives to catch in its beak with great celerity. It will eat insects in a living state, but will not touch them when dead.

"I observed the bird previous to eating a grasshopper, given him in an entire or mutilated state, place the insect upon the perch, keep it firmly fixed with the claws, and divesting it of the legs, wings, &c., devour it, with the head always placed first. The servant who attends upon him to clean the cage, give him food, &c., strips off the legs, wings, &c. of the insects when alive, giving them to the bird as fast as he can devour them. It rarely alights upon the ground, and so proud is the creature of its elegant dress that it never permits a soil to remain upon it, and it may frequently be seen spreading out its wings and feathers, and regarding its splendid self in every direction, to observe whether the whole of its plumage is in an unsullied condition. It does not suffer from the cold weather during the winter season at Macao, though exposing the elegant bird to the bleak northerly wind is always very particularly avoided. Mr. Beale is very desirous of procuring a living female, to endeavour if possible to breed them in his aviary.

"The sounds uttered by this bird are very peculiar; that which appears to be a note of congratulation resembles somewhat the cawing of a raven, but changes to a varied scale of musical gradations, as 'he, hi, ho, haw,' repeated rapidly and frequently, as lively and playfully he hops round and along his perch, descending to the second perch to be admired, and to congratulate the stranger who has made a visit to inspect him; he frequently raises his voice, sending forth notes of such power as to be heard at a long distance, and as it could scarcely be supposed so delicate a bird could utter; those notes are 'whock, whock, whock, whock,' uttered in a barking tone, the last being given in a low tone as a conclusion.

"A drawing of the bird of the natural size was made by a Chinese artist. The bird advanced steadfastly towards the picture, uttering at the same time its cawing congratulatory notes; it did not appear excited by rage, but pecked gently at the representation, jumping about the perch, knocking its mandibles together with a clattering noise, and cleaning them against the perch, as if welcoming the arrival of a companion. After the trial of the picture a looking-glass was brought, to see what effect it would produce upon the bird, and the result was nearly the same; he regarded the reflection of himself most steadfastly in the mirror, never quitting it during the time it remained before him. When the glass was removed to the lower from the upper perch he instantly followed, but would not descend upon the floor of the cage when it was placed so low. . . . . .

"One of the best opportunities of seeing this splendid bird in all its beauty of action, as well as display of plumage, is early in the morning, when he makes his toilet; the beautiful sub-alar plumage is then thrown out, and cleaned from any spot that may sully its purity by being passed gently through the bill; the short chocolate-coloured wings are extended to the utmost, and he keeps them in a steady flapping motion, as if in imitation of their use in flight, at the same time raising up the delicate long feathers over the back, which are spread in a chaste and elegant manner, floating like films in the ambient air.

"I never yet beheld a soil on its feathers. After expanding the wings it would bring them together so as to conceal the head, then bending it gracefully it would inspect the state of its plumage underneath. This action it repeats in quick succession, uttering at the time its croaking notes; it then pecks and cleans its plumage in every part within reach, and throwing out the elegant and delicate tuft of feathers underneath the wings, seemingly with much care, and with not a little pride, they are cleaned in succession, if required, by throwing them abroad, elevating them, and passing them in succession through the bill. Then turning its back to the spectator, the actions above mentioned are repeated, but not in so careful a manner; elevating its tail and long shaft-feathers, it raises the delicate plumage of a similar character to the sub-alar, forming a beautiful dorsal crest, and, throwing its feathers up with much grace, appears as proud as a lady dressed in her full ball-dress. Having completed the toilet, he utters the usual cawing notes, at the same time looking archly at the spectators, as if ready to receive all the admiration that it considers its elegant form and display of plumage demands; it then takes exercise by hopping, in a rapid but graceful manner, from one end of the upper perch to the other, and descends suddenly upon the second perch, close to the bars of the cage, looking out for the grasshoppers which it is accustomed to receive at this time. . . . . .

"His prehensile power in the feet is very strong, and, still retaining his hold, the bird will turn himself round upon the perch. He delights to be sheltered from the glare of the sun, as that luminary is a great source of annoyance to him, if permitted to dart its fervent rays directly upon the cage. The iris frequently expanding and contracting adds to the arch look of this animated bird, as he throws the head on one side to glance at visitors, uttering the cawing notes or barking aloud. . . . . Having concluded, he jumps down to the lower perch in search of donations of living grasshoppers.

"The bird is not at all ravenous in its habits of feeding, but it eats rice leisurely, almost grain by grain. Should any of the insects thrown into his cage fall upon the floor, he will not descend to them, appearing to be fearful that in so doing he should soil his delicate plumage; he therefore seldom or ever descends, except to perform his ablutions in the pan of water placed at the bottom of the cage expressly for his use."

BIRGUS, a genus of Long-Tailed *Crustacea*, approaching the Hermit-Crabs (*Pagurus*) established by Leach. The following are the leading characters:—Middle antennæ having their second articulation crested or tufted; feet of the first pair of legs unequal, terminated by pincers or knob-claws; feet of the second and third pair terminated simply, in other words, by a single nail; fourth pair smaller and didactylous, or terminated by two fingers, one moveable; fifth pair rudimentary, very small, but didactylous; carapace somewhat in the form of a reversed heart, with the apex pointing forwards; post-abdomen or tail orbicular, crustaceous above, the plates being sub-annular, or rudiments of rings.

There are two species recorded, and of these *Birgus Latro*, Leach, *Pagurus Latro*, Fabr. and Lam., *Cancer Latro*, Linn., *Cancer crumenatus*, Börs-Krabbe (Purse-Crab) of Rumphius, is the largest. Its rostrum is terminated by a single point. The pincers are red, the left being much larger than the right, and both deeply toothed. The feet of the next three pairs are toothed on the edges, and marked with undulated streaks. It is a native of Amboyna and other neighbouring islands, where it is said to inhabit the fissures of rocks by day, and to come forth at night to seek its food on the beach. Mr. Cuming found it sufficiently abundant in Lord Hood's Island in the Pacific, but there the Purse-Crabs dwelt at the roots of trees, and not in holes in the rocks. When he met them in his road, they set themselves up in a threatening attitude and then retreated backwards, making both at first and afterwards a great snapping with their pincers. There appears to be a tradition among the natives that it climbs Cocoa-Nut Trees (*Cocos nucifera*) in the night to get the cocoa-nuts. Linnæus, Herbst, and Cuvier repeat this story, which, as Owen observes, is confirmed in a degree by Quoy and Gaimard, who relate that individuals of this species were fed by them for many months on cocoa-nuts alone; and still more amply by the observations communicated to him by Mr. Cuming, who states that these Purse-Crabs climb the *Pandanus odoratissimus*, a kind of palm, for the purpose of feeding on the small nut that grows thereon, and that he saw them in the tree.

Linnæus gives the Antilles as the locality of this Purse-Crab, as well as Amboyna, upon the authority of Rochefort, but this has arisen from a misunderstanding of the text of Rochefort.

In the following passage Rochefort refers to some of the Land-Crabs of the Antilles, and not to the genus *Birgus*:—

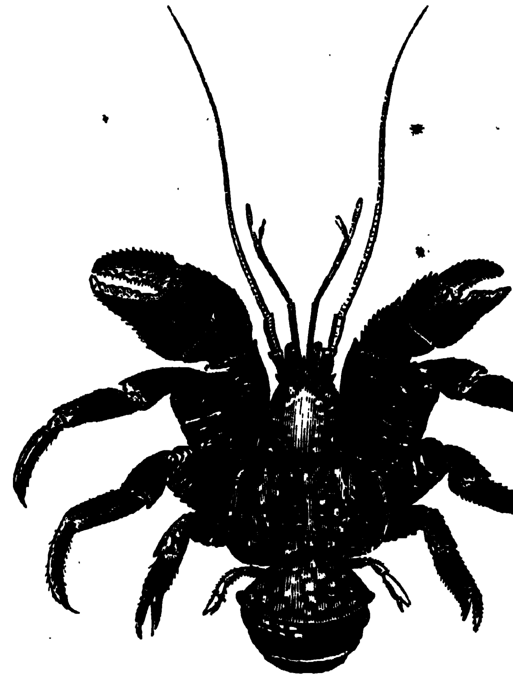
"What is the more worthy of note relating to these crabs is, that once a year, namely, after they are returned from their journey to the sea, they hide themselves entirely in the earth for some six weeks, so that not one appears. During this time they change their skin, or crust, and renew themselves altogether. They place the earth at this season so dexterously at the entrance of their holes, that one cannot perceive the opening. This they do that they may not be exposed to the air. For when they thus throw aside their old garb, the whole of their body is as it were naked, being only covered by a thin and delicate skin, which thickens and hardens by degrees into a crust as solid as that which they have left. Monsieur du Montel reports that he caused people to dig on purpose in those places where there was any appearance of their lying hid, and having met with some of them, that he found that they were enveloped as it were in the leaves of trees, which without doubt served them for nourishment and for a nest during this retreat; but they were so languid and so incapable of supporting the fresh air, that they seemed half dead, though in other respects they were fat and very delicate food. The inhabitants of the Isles call them at this period Purse-Crabs, and esteem them much. He saw quite close to them their old covering, that is to say, their shell, which appeared as entire as if the animal had been still within. What is wonderful is, that though he employed very good eyes, he could scarcely observe the opening or slit whence the body of the animal had come forth and had disengaged itself from this prison. Nevertheless, after having taken great care he remarked in the empty shells a small separation near the tail, by which the crabs had extricated themselves."

Then follows the most approved way of dressing these Land-Crabs for the table, a mode which is still in practice with little variation in the West Indies at the present day.

In a manuscript entitled 'Mémoires en Forme de Dictionnaire contenant l'Histoire Naturelle notamment de Cacao, l'Indigo, le Sucre, et le Tabac, Par M. ———, Inspecteur pour la Compagnie de Chandernagor,' there is a very full account of the Land-Crabs (Tourlouroux) of the Antilles, and the writer of the manuscript, speaking of their condition after they have thrown off their old crusts, says, "If they take the crabs then, they find them covered only with a slight red skin, tender and delicate as moistened parchment; the crabs are then much more delicious than they are at any other season; they call them at that period Purse-Crabs" (tom. ii. p. 526). The manuscript is without date, but was written after the publication of Labat's works, which the writer quotes.

Birgus Latro, which grows to a large size, is said to be excellent food when properly prepared. It was a favourite diet with the natives of Lord Hood's Island, but Mr. Cuming did not taste it.

There are specimens in the British Museum. There is only one species of this genus.



Purse-Crab (*Birgus Latro.*)

BIROSTRITES, a genus of Fossil *Mollusca* named by Lamarck. He has placed it under his family *Rudistes*, a family which, as Mr. G. Sowerby observes, might be struck out; for there can be hardly any doubt that Lamarck has misconceived or misplaced the genera of which it is composed. G. Sowerby, from an examination of the cast of the inside of the shell, expresses his conviction that *Birostrites* ought to be placed next to *Diceras*, or at least in the same family with *Chama* and *Diceras*, inasmuch as it accords very nearly with those shells in its internal characters. Rang has placed the genera *Batolites*, *Raphanistes*, and *Amplexus*, near to this genus.

The following is Lamarck's description of this singular fossil:—Shell composed of two pieces or valves, which do not unite by the edges of their base, one enveloping the other, and the dorsal disc of each being elevated into a nearly straight cone slightly arched within. These horn-shaped valves are unequal, and diverge obliquely under the form of a very open V. It seems as if one valve came out of the base of the other, and it is always the shortest that is enveloped. *Birostrites inæquilobus* is the only species which Lamarck records.

BIRTHWORTS. [ARISTOLOCHIACEÆ.]

BISH. [BIKH.]

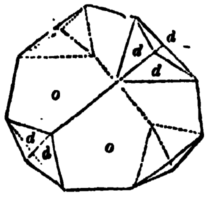
BISMORE, a name given in the Orkneys to the 15-spined Stickleback. [GASTEROSTEUS.]

BISMUTH, a metal that was unknown to the ancients. It was referred to by Agricola in his work on mining in 1529, and was subsequently described by Stahl and Dufay.

The minerals in which this metal constitutes the principal ingredient are comparatively few in number; and of these only two species are of any importance in a commercial point of view, namely, the native bismuth, and its sulphurets. The general characters of these minerals are the following. Before the blow-pipe they are readily fused and reduced to a metallic state, the regulus itself gradually subliming if the flame be continued, leaving on the charcoal an orange-yellow areola, which however may readily be made to disappear in the deoxidising flame. When the metallic regulus is fused in an open glass tube, a yellowish-white sublimate is obtained, and the regulus itself becomes covered by the fused oxide, which while hot is of a dark brown colour but assumes a yellow tint on cooling. These minerals are all of them soluble in strong nitric acid, the solution yielding a white precipitate on being dropped into water. They are known and described by mineralogists under the following names:—*Native* or *Octahedral Bismuth*, *Bismuth-Ochre*, *Prismatic Bismuth-Glance*, *Needle-Ore* or *Acicular Bismuth-Glance*, called by Phillips *Plumbo-Cupriferous Sulphuret of Bismuth*, *Tellurbismuth*, formerly known by the name of *Molybdan Silver*.

Native or *Octahedral Bismuth* is sometimes found crystallised: the observed forms are the octahedron, the tetrahedron, and combinations of the latter with the dodecahedron, which produce the shape seen in the accompanying figure.

The faces marked *o* belong to the tetrahedron and those marked with *d* to the rhombic dodecahedron. The edge between the faces *o* is therefore 70° 32′, between the faces *d* 120°, and in the edges of combination between *o* and *d* 144° 44′. These crystals are generally very imperfect, and the faces rough and uneven; they possess a perfect cleavage parallel to the faces of the octahedron. The hardness varies from 2 to 2·5, the specific gravity from 9·6 to 9·8. The crystals are opaque, possess the metallic lustre, and the fresh fracture presents a reddish silver white; but the surface is usually tarnished, owing to partial oxidation, and presents a variegated appearance of gray, red, and blue colours. They may be considered as presenting us with the metal Bismuth in a pure state, the only foreign matter being traces of arsenic. The occurrence of crystals is somewhat rare, this mineral being usually found in feathery and arborescent forms, and also in dentiform concretions in veins, traversing gneiss, mica, and clay-slates, where it is usually accompanied by ores of silver, cobalt, nickel, and iron. It is found at St. Columb and Botallack mines in Cornwall, and at Castle-Carrock in Cumberland, but in much greater abundance in the mines of Saxony and Bohemia, at Johann-Georgenstadt, Annaberg, Altenberg, Schneeberg, and at Joachimsthal, from whence the greater portion of the Bismuth of commerce is obtained. It is also found at Beiber in Hainau, at Löling in Carinthia, and in the Sophia mine at Wittichen in Fürstenberg.



The *Bismuth-Ochre* is a rare mineral, which occurs massive and disseminated. It is of a straw-yellow, passing sometimes into a light yellowish gray. Its specific gravity is 4·36, and its chemical constitution—

Bismuth	89·87
Oxygen	10·13

It usually contains small quantities of arsenic and oxide of iron as impurities. Its known localities are St. Agnes, Cornwall; Schneeberg and Johann-Georgenstadt, in Saxony; and Joachimsthal, in Bohemia.

Bismuth-Glance, *Bismutite*, a Carbonate of Bismuth, occurs in four-sided prisms of unknown dimensions, but it is stated by Phillips to have angles about 91° and 89°. It is further characterised by its metallic lustre, and lead-gray approaching steel-gray colour, and from its possessing a perfect cleavage in the direction of the short diagonal, and one less perfect in the direction of the base. According to Mohs the hardness is between 2 and 2·5, and the specific gravity 6·549. It also occurs massive of a granular composition, or columnar, the individuals being long and straight, and aggregated in various directions. According to the analysis of H. Rose of a specimen from Reddarhyttan, it is thus composed:—

Sulphur	18·49	18·72
Bismuth	81·51	80·98

Before the blow-pipe sulphur is first driven off, which is followed by a sublimate having the odour of tellurium, and afterwards the characters are the same as those of the other minerals of Bismuth.

Bismuth-Blende is a Silicate of Bismuth.

Other minerals in which Bismuth occurs are *Needle-Ore* and *Tellurbismuth*. *Needle-Ore* is also called *Acicular Bismuth*. It is a sulphuret of bismuth, lead, and copper, containing a trace of gold. It comes from Siberia. *Tellurbismuth*, or *Tetradymite*, is composed of tellurium and bismuth. It has a foliated structure, and a pale steel-gray colour. It comes from Schemnitz, and also from Brazil.

(Dana, *Mineralogy*.)

BISON, the name of a genus of Ruminant Animals belonging to the family *Bovidæ*. The genus *Bison* comprehends two living species, one of them European, now become very scarce and verging towards extinction; the other American, and, notwithstanding the advances of man, still multitudinous.

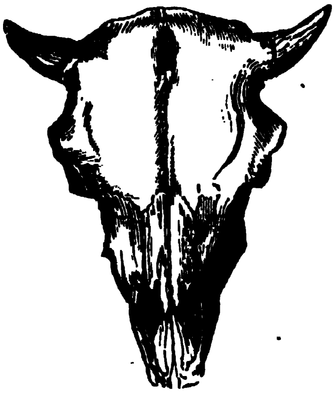
European Bison.

As much difference of opinion has prevailed with regard to the historical records and true characters of the first or European species of Bison, we shall quote a few of the synonyms of this animal as given in the Catalogue of the Specimens of Mammalia, in the British Museum, by Dr. J. E. Gray.

The Bison Aurochs, or European Bison, is the *Bos Bison* of Linnæus; *Bison Bonassus*, Dr. J. E. Gray; *Bos Urus*, Boddaert; *Bos Bison Aurochs*, Lesson; *Bos Taurus Urus*, Gmelin; *Bos Bonassus*, Brisson; *Bison Europæus*, Owen; *Bos Bison seu Bonassus*, Wagner; *Bison jubatus*, Pliny; *Bison*, Gesner, Aldrovandus, and Gilibert; *Urus*, Cæsar; *Aurochs*, Cuvier, Buffon, and Desmoulins; *Bonasus*, Pliny, Gesner, Klein, Buffon, and Ray. It is also the Urochs, Auer-Ochse or Auer-Ochs, Wald-Ochse, Wilder Ochs, Berg-Ochs, Buckel-Ochs, Afrikanischer Wilder Ochs, Preussische und Lithanische Auer-Ochs, Zurb, and Manistier, of various German writers. To these various synonyms we may now add that of *Bison priscus* of Owen, as there is no doubt that the bones of the Great Fossil Aurochs belong to the same species as those now living in the forests of Lithuania.

The difficulty of identifying this animal has arisen from the fact, that besides the Bison there existed at one time in Europe and in Great Britain a wild ox (*Bos primigenius*), whose remains are numerous, but which has undoubtedly become quite extinct. Pennant, in his 'British Zoology,' after stating his belief that the ancient wild cattle of our island were the *Bisontes jubati* of Pliny, thus continues:—"The Urus of the Hercynian forest, described by Cæsar, book vi., was of this kind, the same which is called by the modern Germans Aurochs, that is, *Bos sylvestris*." Now let us look at Cæsar's description. "These Uri are little inferior to elephants in size, but are bulls in their nature, colour, and figure. Great is their strength and great their swiftness, nor do they spare man or beast when they have caught sight of them. These, when trapped in pitfalls, the hunters diligently kill. The youths exercising themselves by this sort of hunting are hardened by the toil; and those among them who have killed most, bringing with them the horns as testimonials, acquire great praise. But these Uri cannot be habituated to man or made tractable, not even when young. The great size of the horns, as well as the form and quality of them, differs much from the horns of our oxen. These, when carefully selected, they ring round the edge with silver and use them for drinking-cups at their ample feasts." Though there are parts of this description applicable to the European Bison, there is one striking character which forbids us to conclude that Cæsar's *Urus* was identical with it. A glance at the European Bison will convince us that it never could have afforded the horns whose amplitude Cæsar celebrates. In the 'Archæologia,' vol. iii. p. 15, it is stated that the Borstal horn is supposed to have belonged to the Bison or Buffalo. That it might have belonged to a Buffalo is not impossible, but that it did not belong to a Bison is sufficiently clear from the following description: "It is 2 feet 4 inches long on the convex bend, and 23 inches on the concave. The inside at the large end is 3 inches diameter, being perforated there so as to leave the thickness only of half an inch for about 3 inches deep; but farther in it is thicker, being not so much or so neatly perforated." This horn was no doubt supplied by the Great Fossil Ox, the *Bos primigenius*. Horns were anciently used amongst us in the conveyance of inheritances; of which we have examples in the Borstal horn, and the Pusey horn. These probably belonged to the Great Fossil Ox. That the common Ox could not be descended from the Bison as has been conjectured by some, is proved by the fact that the Aurochs or European Bison has 14 pairs of ribs, while the Ox has but 13, and that the legs of the Aurochs are more slender and longer than those of the Ox and true Buffalo. The European Bison, moreover, has but five lumbar vertebræ, while the other oxen, with the exception of the American Bison, which has only four according to Cuvier, possess six. [BOVIDÆ.]

"The front of the common Ox," says Cuvier, "is flattened, and even in a small degree concave; that of the Aurochs is rounded into convexity (bombé), though rather less than that of the Buffalo. It is square in the Ox, its height being nearly equal to its breadth, taking for its base an imaginary line between the orbits. In the Aurochs, with the same mode of measurement, it is much broader than it is high, in the proportion of three to one. The horns are attached in the Ox to the extremities of the most elevated salient line of the head, that, namely, which separates the occiput from the front; in the Aurochs this line is two inches farther back than the root of the horns. The plane of the occiput makes a sharp angle with the front in the Ox; this angle is obtuse in the Aurochs; and lastly, this quadrangular plane of the occiput, as it is in the Ox, represents a half circle in the Aurochs."

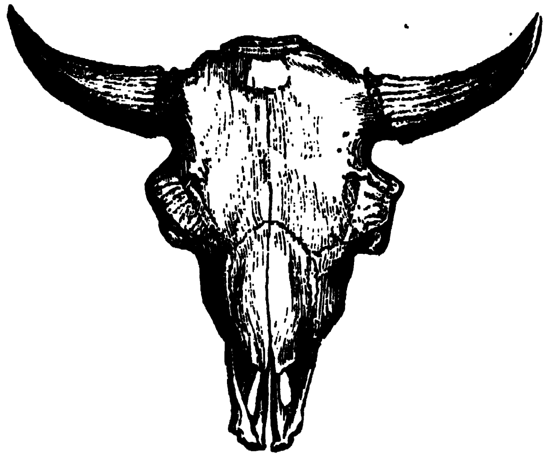


Skull of European Bison, front view.

Profile of the same.

The figures here given were taken from the skull of the European Bison or Aurochs in the museum at Paris. This must have been a young animal, as will be seen from comparing the representation of its skull with that of the following specimen.

There is now no doubt that the *Bison jubatus* of Pliny (book viii. c. 15, and xxviii. c. 10), which he seems to distinguish from the *Urus*, was the European Bison or Aurochs; and though in the 15th chapter of the 8th book he mentions the tradition of a wild beast in Pæonia called a *Bonasus*, after he has dismissed his *Bisontes jubati*, and with every appearance of a conclusion on his part that the *Bonasus* and *Bison* were not identical his own description, when compared with that of Aristotle, will leave little doubt that the *Bison jubatus* and *Bonasus* of Pliny and others, the **Βόνασσος** or **Βόνασος** of Aristotle (for the word is written both ways), and the **Βίσων** of Oppian, were no other than the European Bison.

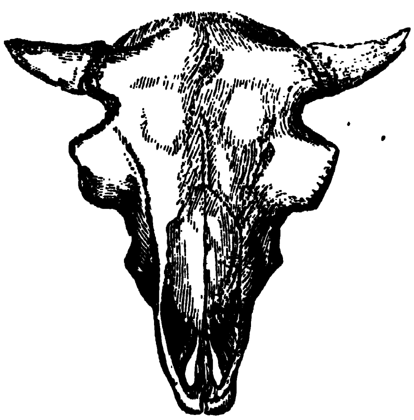


Skull of old European Bison, front view.

Profile of the same.

European Bison (*Bison Europæus*).

Cuvier, in his 'Ossemens Fossiles,' states it to be his opinion that this animal, the largest or at least the most massive of all existing quadrupeds after the rhinoceros, is a distinct species which man has never subdued. Following out this subject with his usual industry and ability, that great naturalist goes on to state that if Europe possessed a *Urus*, a Thur of the Poles, different from the Bison or the Aurochs of the Germans, it is only in its remains that this species can be traced. Such remains are found in the skulls of a species of Ox different from the Aurochs, in the superficial beds of certain districts. This Cuvier was of opinion must have been the true *Urus* of the ancients, the original of our domestic Ox, the stock perhaps whence our wild cattle descended. Professor Owen, in his 'British Fossil Mammals,' has fully established the distinction between the Aurochs and the Great Fossil Ox, the *Urus* of the ancients, but he has shown that it is impossible that any of our forms of oxen or wild cattle should have been descended from this species which is now extinct. [BOVIDÆ.] The head given below is figured by Cuvier as of doubtful character, but if compared with the skull of the Aurochs there can be little doubt of its identity.



Skull of supposed Fossil Aurochs, front view.

Profile of the same.

The remains of the Aurochs have been found abundantly on the continent of Europe, and been described by Faujas, Cuvier, and H. von Meyer. Some of these carry the antiquity of this animal as far back as the period of the extinct pachyderms of the newer Pliocene deposits. On comparing these with recent specimens of the Aurochs from the Lithuanian forests, they are found to be generally of larger size, to have longer and somewhat less bent horns, but they present no satisfactory specific distinction.

That the Aurochs existed formerly in Great Britain is attested from the discovery of remains of the cranium and horn-cores from various newer Tertiary Fresh-Water deposits, especially in the counties of Kent and Essex along the borders of the Thames. In the hall of the Geological Society of London is a cranium with horn-cores, obtained by Mr. Warburton from the Fresh-Water Tertiary deposits of Walton in Essex. A broken skull was also discovered by Mr. H. E. Strickland, in the Fresh-Water Drift at Cropthorne, Worcestershire. Professor Phillips, in his 'Geology of Yorkshire,' records the discovery of the skull with the cores of the horns and the teeth at Boilbecks, in Yorkshire. It was accompanied with the remains of fresh-water *Mollusca* and of the Mammoth, Rhinoceros, a species of *Felis*, a large Horse, a large Deer, Wolf, &c. It is to be regretted that the entire skeleton of the same individual has not hitherto been discovered, in order that a comparison of the number of ribs between this elder Bison, and the European and American Bisons of the present day might be made.

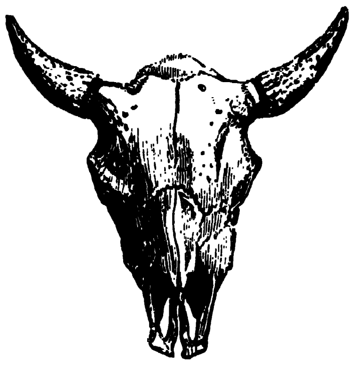
The European Bison, as found at the present day, has a very broad head and arched forehead. The eyes are large and dark; the hair on the forehead is long and wavy, and under the chin and breast it forms a kind of beard. In the winter the whole of the neck, hump, and shoulders are covered with a long dusky-brown hair, intermingled with a soft fur. The long hair is cast in the summer and renewed in the winter. The tail is of moderate length, covered with hair, and is terminated in a large tuft. The females are not so large as the males, and have not so much hair on their bodies.

The districts in which this animal is now found living are comparatively limited, as it appears to be confined to the forests of Lithuania, Moldavia, Wallachia, and some parts of the Caucasus. These animals have never been domesticated, but herds of them are protected in certain localities in the forest of Bialowieza in Lithuania, under the direction of the Emperor of Russia. There are twelve herds thus kept, each herd being under the superintendence of one herdsman. The estimated number of all the herds is 800. They feed on grass and brushwood, and the bark of young trees, especially the willow, poplar, ash, and birch. They do not attain their full stature till their sixth year. They are very shy, and can only be approached from the leeward, as their smell is exceedingly acute. When accidentally fallen in with they become furious, and passionately assail the intruder. When taken young they become accustomed to their keeper, but the approach of other persons excites their anger. Two young specimens were presented to the Zoological Society of London by the Emperor of Russia. Although it had been stated that the Aurochs had natural enmity to domestic cattle, and that the young obstinately refused to be suckled by the domestic cow, the calves sent by the Emperor were suckled by a cow in the Regent's Park Gardens, and became very speedily attached to their foster-mother. These creatures unfortunately died a few months after they had been brought to this country. A very fine specimen was presented to the British Museum by the Emperor of Russia, which is now to be seen stuffed in the collection. The dimensions of this animal are as follows:—

	Ft.	In.
Length from the nose to the insertion of the tail	9	10
Height at the withers	5	6
Height at the rump	4	11
Length of head	1	8
Length of tail	3	0

American Bison.

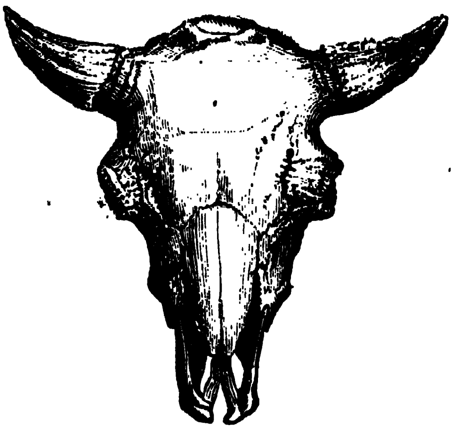
We have seen that the European Bison has fourteen pairs of ribs, while the common Ox has but thirteen. The specific difference of the American Bison is marked by its having fifteen ribs on each side. Thus, in the Bisons, the supplementary ribs spring from the anterior lumbar vertebræ, or rather from vertebræ which are lumbar as far as regards their situation, but dorsal when considered in relation to their functions. The contour of the skull has much in common with that of the European species, but its development, and indeed that of the whole frame, is much inferior in the female. Beneath is represented the skull of a young female American Bison,—



Skull of young female American Bison, front view.

Profile of the same.

and we shall at once see how tame and weak its chiselling is when compared with that of the old male.



Skull of old male American Bison, front view.

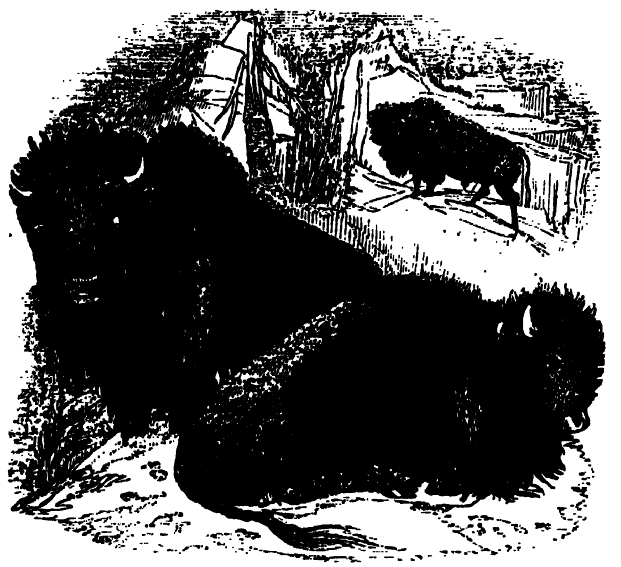
Profile of the same.

The American Bison has many points of similarity with the Aurochs. In both we have the huge head and the lengthened spinal processes of the dorsal vertebræ for the attachment of the brawny muscles that support and wield it. In both we have the conical hump between the shoulders in consequence, and the shaggy mane in all seasons; and each presents a model of brute force, formed to push and throw down.

This is the *Taurus Mexicanus* of Hernandez, who gives a woodcut of the beast, but not a good one; the Taureau Sauvage of Hennepin, who also gives a figure of it, not better than that of Hernandez, and probably a copy from it; the Buffalo of Lawson, Catesby, &c., of the Hudson's Bay traders, and of the Anglo-Americans generally; the Bison of Ray and Pennant; *Bos Americanus* of Gmelin; American Wild Ox or Bison of Warden; Peecheek of the Algonquin Indians; Moostoosh of the Crees; and Adgiddah of the Chippewayans, according to Sir John Richardson.

Pennant says, "In America these animals are found in the countries

600 miles west of Hudson's Bay; this is their most northern residence. From thence they are met with in great droves as low as Cibole (on the authority of Purchas) in lat. 33°, a little north of California, and also in the province of Mivera in New Mexico. The species instantly ceases south of those countries. They inhabit Canada to the west of the lakes; and in greater abundance in the rich savannahs which border the river Mississippi and the great rivers which fall into it from the west, in Upper Louisiana. There they are seen in herds innumerable, promiscuously with multitudes of stags and deer during morning and evening, retiring in the sultry heats into the shade of tall reeds which border the rivers of America."



American Bison (*Bison Americanus*), Females. A Bull in the distance.

American Bison (*Bison Americanus*), a Bull.

Joseph Sabine, in the Appendix to 'Franklin's Narrative,' says that they are abundant in all parts of North America, wherever the progress of cultivation has not interfered with their range, and that they are extremely numerous on the plains of the Saskatchewan River. They are also found, he observes, though less plentifully, in the woods as far north as Great Slave Lake, The most northern situation in which they were observed by Sir John Franklin's party was Slave Point, on the north side of the lake. In the same work it is stated that the natives say that the Wood Buffaloes, as they are called, are larger than those of the plains, but the difference is not material.

Sir John Richardson, in his 'Fauna Boreali-Americana,' gives the following compendious history of the geographical range of the American Bison:—"At the period when Europeans began to form settlements in North America, this animal was occasionally met with on the Atlantic coast; but even then it appears to have been rare to the eastward of the Appalachian Mountains, for Lawson has thought it to be a fact worth recording, that two were killed in one season on Cape Fear River. As early as the first discovery of Canada, it was unknown in that country, and no mention of it whatever occurs in the 'Voyages du Sieur de Champlain Xaintongeois,' nor in the 'Nova Françia' of De Monts, who obtained the first monopoly of the fur-trade. Theodat, whose 'History of Canada' was published in 1636, merely says that he was informed that bulls existed in the remote western countries. Warden mentions that at no very distant date herds of them existed in the western parts of Pennsylvania, and that as late as the year 1766 they were pretty numerous in Kentucky; but they have gradually retired before the white population, and are now, he says, rarely seen to the south of the Ohio, on the east side of the Mississippi. They still exist, however, in vast numbers in Louisiana, roaming in countless herds over the prairies that are watered by the Arkansas, Platte, Missouri, and upper branches of the Saskatchewan and Peace rivers. Great Slave Lake, in lat. 60°, was at one time the northern boundary of their range; but of late years, according to the testimony of the natives, they have taken possession of the flat limestone district of Slave Point, on the north side of that lake, and have wandered to the vicinity of Great Marten Lake, in lat. 63° or 64°. As far as I have been able to ascertain, the limestone and sandstone formations lying between the great Rocky Mountain ridge and the lower eastern chain of primitive rocks, are the only districts in the fur countries that are frequented by the bison. In these comparatively level tracts there is much prairie land, on which they find good grass in the summer, and also many marshes overgrown with bulrushes and carices,* which supply them with winter food. Salt-springs and lakes also abound on the confines of the limestone, and there are several well-known salt-licks where bisons are sure to be found at all seasons of the year. They do not frequent any of the districts formed of primitive rocks, and the limits of their range to the eastward, within the Hudson's Bay Company's territories, may be nearly correctly marked on the map by a line commencing in long. 97° on the Red River, which flows into the south end of Lake Winnipeg, crossing the Saskatchewan to the westward of Basquiau Hill, and running from thence by the Ath[illegible]scow to the east end of Great Slave Lake. Their migrations to the westward were formerly limited by the Rocky Mountain range, and they are still unknown in New Caledonia and on the shores of the Pacific to the north of the Columbia River, but of late years they have found out a passage across the mountains, near the sources of the Saskatchewan, and their numbers to the westward are said to be annually increasing. In 1806, when Lewis and Clarke crossed the mountains at the head of the Missouri, bison-skins were an important article of traffic between the inhabitants on the east side and the natives to the westward. Farther to the southward, in New Mexico and California, the bison appears to be numerous on both sides of the Rocky Mountain chain."

The districts of America which these animals inhabit are described very graphically in Washington Irving's 'Tour on the Prairies.'

The American male Bison, when at its full size, is said to weigh 2000 lbs., though 12 or 14 cwt. is considered a good weight in the fur countries. Sir John Richardson gives 8½ feet as its length, exclusive of the tail, which is 20 inches, and upwards of 6 feet as its height at the fore quarters. The head is very large, and carried low; the eyes are small, black, and piercing; the horns are short, small, sharp, set far apart, for the forehead is very broad, and directed outwards and backwards, so as to be nearly erect, with a slight curve towards the outward-pointing tips. The hump is not a mere lump of fatty secretion, like that of the zebu, but consists, exclusive of a deposit of fat which varies much in quantity, of the strong muscles attached to the highly-developed spinous processes of the last cervical and first dorsal vertebræ, forming fit machinery for the support and movement of the enormous head. The chest is broad, and the legs are strong; the hind parts are narrow, and have a comparatively weak appearance. The tail is clothed with short fur-like hair, with a long, straight, coarse, blackish-brown tuft at the end. In winter the whole body is covered with long shagged hair, which in summer falls off, leaving the blackish wrinkled skin exposed, except on the forehead, hump, fore quarters, under-jaw, and throat, where the hair is very long and shaggy, and mixed with much wool. Catesby observes that on the forehead of a bull the hair is a foot long, thick, and frizzled, and of a dusky black colour; that the length of this hair hanging over their eyes impedes their flight, and is frequently the cause of their destruction; but that this obstruction of sight is in some measure supplied by their good noses, which are no small safeguard to them. A bull, says he, in summer, with his body bare and his head muffled with long hair, makes a very formidable appearance. In summer the general colour of the hair is between dark-umber and liver-brown, and lustrous. The tips of the hair as it lengthens in winter are paler, and before it is shed in summer much of it becomes of a pale dull yellowish-brown. In the female the head is smaller, and the hair on the fore parts is not so long as it is in the male.

Congregating in vast herds, these animals are said to cover the wide-extended savannahs of the more southern districts of the north for miles in extent. "Such was the multitude," say Lewis and Clarke, speaking of an assemblage of Bisons as they crossed the water, "that although the river, including an island over which they passed, was a mile in length, the herd stretched as thick as they could swim completely from one side to the other." The same travellers, speaking of another of these grand spectacles, say—"If it be not impossible to calculate the moving multitude which darkened the whole plains, we are convinced that 20,000 would be no exaggerated number." Catesby, after stating that they range in droves, feeding on the open savannahs morning and evening, says that in the sultry time of the day they retire to shady rivulets and streams of clear water gliding through thickets of tall canes. Dr. James had an opportunity of observing them on such occasions, and he thus describes their march:—"In the middle of the day countless thousands of them were seen coming in from every quarter to the stagnant pools;" and in another place he says that their paths are as frequent and almost as conspicuous as the roads in the most populous parts of the United States.

---

* *Carex* is the name of a genus of *Cyperaceæ*, a family of plants nearly allied to the Grasses.

The Bisons, in truth, are a wandering race, the motives of their restlessness being either disturbance by hunters or change of pasture. After the fire has cleared the prairie of all the old herbage, the delicately tender grass which springs up in the room of the old wiry bents that fed the flame offers the most grateful food to the migratory Bisons: such spots are well known to the hunter as points of attraction to these animals. In the winter, when the snow lies deep over the vegetation, they scrape it away with their feet to get at the grass.

Fierce and terrible are the fights among the bulls in the rutting season, and perilous is the condition of the man who then approaches them. For the greatest part of the year the bulls and cows live in separate herds, but at all seasons, according to Sir John Richardson, one or two old bulls generally accompany a large herd of cows.

These powerful beasts are in general shy, and fly from the face of man till they are wounded; they then become furious, and pursue their enemy with the most vindictive spirit, as we shall presently see; but we must first say a word or two on some of the different modes of hunting them. Du Pratz and Charlevoix give several particulars of the chase of these animals by the Indians. If the rifle be used the hunter is careful to go against the wind, for the sense of smelling is so exquisite in the Bison that it will otherwise get scent of him, and precipitately retire. If he gets within rifle-distance he is careful so to take his aim that the beast may drop at once, and not be irritated by an ineffectual wound.

But the great hunting is, or rather was, somewhat after the manner of the Scottish 'tinchel.' A great number of men divide and form a vast square. Each band sets fire to the dry grass of the savannah where the herds are feeding. When the affrighted beasts perceive the fire approaching on all sides they retire in confusion to the centre of the square, where the bands close upon them and kill them, as they are huddled together in heaps, without hazard: 1500 or 2000 beeves have been given as the produce of such an expedition.

Sir John Franklin, in his account of his first voyage, gives us the following information. After stating that the Stone Indians are so expert with the bow and arrow that they can strike a very small object at a considerable distance, and shoot with sufficient force to pierce through the body of a buffalo when near, he thus describes a buffalo or bison pound:—

"The buffalo-pound was a fenced circular space of about 100 yards in diameter; the entrance was banked up with snow to a sufficient height to prevent the retreat of the animals that once have entered. For about a mile on each side of the road leading to the pound, stakes were driven into the ground at nearly equal distances of about 20 yards; these were intended to represent men, and to deter the animals from attempting to break out on either side. Within 50 or 60 yards from the pound branches of trees were placed between these stakes to screen the Indians, who lie down behind them to await the approach of the buffalo. The principal dexterity in this species of chase is shown by the horsemen, who have to manœuvre round the herd in the plains so as to urge them to enter the roadway, which is about a quarter of a mile broad. When this has been accomplished they raise loud shouts, and, pressing close upon the animals, so terrify them that they rush heedlessly forward towards the snare. When they have advanced as far as the men who are lying in ambush, they also rise, and increase the consternation by violent shouting and firing guns. The affrighted beasts having no alternative run directly to the pound, where they are quickly dispatched either with an arrow or gun. There was a tree in the centre of the pound on which the Indians had hung strips of buffalo flesh and pieces of cloth, as tributary or grateful offerings to the Great Master of life; and we were told that they occasionally place a man in the tree to sing to the presiding spirit as the buffaloes are advancing, who must keep his station until the whole that have entered are killed."

The same author further proceeds as follows:—"Other modes of killing the buffalo are practised by the Indians with success; of these, the hunting them on horseback requires most dexterity. An expert hunter, when well mounted, dashes at the herd, and chooses an individual which he endeavours to separate from the rest. If he succeeds he contrives to keep him apart by the proper management of his horse, though going at full speed. Whenever he can get sufficiently near for a ball to penetrate the beast's hide he fires, and seldom fails of bringing the animal down; though of course he cannot rest the piece against the shoulder nor take a deliberate aim. On this service the hunter is often exposed to considerable danger from the fall of his horse in the numerous holes which the badgers make in these plains, and also from the rage of the buffalo, which, when closely pressed, often turns suddenly, and, rushing furiously on the horse, frequently succeeds in wounding it or dismounting the rider. Whenever the animal shows this disposition, which the experienced hunter will readily perceive, he immediately pulls up his horse, and goes off in another direction." The reader will find some animated descriptions of such encounters in 'The Tour on the Prairies,' before alluded to. A great deal of interesting matter on the habits of these animals will also be found in Catlin's 'Letters and Notes on the North American Indians.'

"When the buffaloes are on their guard," as Sir John Franklin observes, "horses cannot be used in approaching them; but the hunter dismounts at some distance, and crawls in the snow towards the herd, pushing his gun before him. If the buffaloes happen to look towards him, he stops, and keeps quite motionless, until their eyes are turned in another direction; by this cautious proceeding a skilful person will get so near as to be able to kill two or three out of the herd. It will easily be imagined this service cannot be very agreeable when the thermometer stands 30° or 40° below zero, as sometimes happens in this country."

This chase of the bison is not unattended with danger, "for," says Catesby, "when wounded they are very furious, which cautions the Indians how they attack them in open savannahs, where no trees are to screen them from their fury. Their hoofs, more than their horns, are their offensive weapons, and whatever opposes them is in no small danger of being trampled into the earth."

Sir John Richardson, in his 'Fauna Boreali-Americani,' observes that "the bisons are less wary when they are assembled together in numbers, and that they will then often blindly follow their leaders, regardless of, or trampling down, the hunters posted in their way." He further states that, though the gait of these animals may appear heavy and awkward, they will have no great difficulty in overtaking the fleetest runner, and gives the following account of the determined violence with which a wounded Bison assails its enemy:—"While I resided at Carlton-House," writes Sir John Richardson, "an accident of this kind occurred. Mr. Finnan M'Donald, one of the Hudson's Bay Company's clerks, was descending the Saskatchewan in a boat, and one evening, having pitched his tent for the night, he went out in the dusk to look for game. It had become nearly dark when he fired at a bison bull, which was galloping over a small eminence, and as he was hastening forward to see if his shot had taken effect, the wounded beast made a rush at him. He had the presence of mind to seize the animal by the long hair on its forehead as it struck him on the side with its horn, and, being a remarkably tall and powerful man, a struggle ensued, which continued until his wrist was severely sprained, and his arm was rendered powerless; he then fell, and after receiving two or three blows became senseless. Shortly afterwards he was found by his companions lying bathed in blood, being gored in several places, and the bison was couched beside him, apparently waiting to renew the attack had he shown any signs of life. Mr. M'Donald recovered from the immediate effects of the injuries he received, but died a few months afterwards. Many other instances might be mentioned of the tenaciousness with which this animal pursues its revenge; and I have been told of a hunter having been detained for many hours in a tree by an old bull which had taken its post below to watch him. When it contends with a dog, it strikes violently with its fore feet, and in that way proves more than a match for an English bull-dog."

The same writer says that the favourite Indian method of killing the Bison is by riding up to the fattest of the herd on horseback, and shooting it with an arrow; and he speaks of the imposing spectacle which is afforded when a large party of hunters are engaged in this way on an extensive plain, and of the skill and agility displayed by the young men on such occasions. The horses, it appears, seem to enjoy the sport as much as their riders, and are very active in eluding the shock of the animal should it turn on its pursuer. It should be remembered, on such occasions, that when the Bison runs it leans very much first to one side for a short time, and then to the other, and so on alternately. This account is confirmed by Catlin in the work above quoted.

Sir John Richardson also confirms Sir John Franklin in the assertion that the most generally practised plan of shooting the Bisons is by crawling towards them from the leeward, and that in favourable places great numbers are taken in pounds.

Though the risk of the chase be considerable the reward is great; for there are few animals that minister more largely to the wants and even to the comforts of man than the American Bison. The horns are converted into powder-flasks; the hide, which, according to Catesby, is too heavy for the strongest man to lift from the ground, is very valuable, and is used for a variety of purposes. Purchas relates that in old times the Indians made the best of targets of it; and Catesby says that they make their winter moccassins of it also, but that, being too heavy for clothing, it is not often put to that use. Sir John Richardson informs us that the wool has been manufactured in England into a remarkably fine and beautiful cloth; and that in the colony of Osnaboyna, on the Red River, a warm and durable coarse cloth is formed of it. Catlin says that "there are by a fair calculation more than 300,000 Indians who are now subsisting on the flesh of the buffaloes, and by these animals supplied with all the luxuries of life which they desire, as they know of none others."

"The flesh of a bison in good condition," says the author last quoted, "is very juicy and well-flavoured, much resembling that of well-fed beef." Others describe it as bearing the same relation to common beef that venison bears to mutton. The tongue, when well cured, is said to surpass that of the common ox as a relish. All concur in the praises of the delicious hump, rich, savoury, and tender. This is the fleshy part that covers the long spinous processes of the anterior dorsal vertebræ, and is called 'bos' by the Canadian voyagers, and 'wig' by the Orkney men in the service of the Hudson's Bay Company, according to Sir John Richardson, who says that much of the pemmican used by the voyagers attached to the fur companies is made of bison meat, procured at their posts on the Red River and Saskatchewan: he adds, that one bison cow in good condition furnishes dried meat and fat enough to make a bag of pemmican weighing 90 lbs.

The fat bulls yield a great quantity of tallow; and Du Pratz records that 150 lbs. have been procured from a single beast. Pennant says that these over-fed animals usually become the prey of wolves, for, by reason of their great unwieldiness, they cannot keep up with the herd; and, on the authority of Du Pratz, gives the following account of their sagacity in defending themselves against the atacks of their fierce persecutors:—"When they scent the approach of a drove of those ravenous creatures, the herd flings itself into the form of a circle: the weakest keep in the middle, the strongest are ranged on the outside, presenting to the enemy an impenetrable front of horns: should they be taken by surprise, and have recourse to flight, numbers of the fattest or the weakest are sure to perish." Sir John Richardson however, speaking of the numerous wolves on the sandy plains which, lying to the eastward of the Rocky Mountains, extend from the sources of the Peace and Saskatchewan rivers towards the Missouri, says that there bands of them hang on the skirts of the buffalo herds, and prey upon the sick and straggling calves, but that they do not, under ordinary circumstances, venture to attack the full-grown animal. As a proof of this, he adds, that the hunters informed him that they often saw wolves walking through a herd of bulls without exciting the least alarm, and that the marksmen, when they crawl towards a bison for the purpose of shooting it, occasionally wear a cap with two ears in imitation of the head of a wolf, knowing from experience that they will be suffered to approach nearer in that guise.

The Grisly Bear is one of the most formidable enemies of the American Bison; and the strongest bull goes down before him. [Bear.]

The Indian is too wild in his habits to submit to the fetters which an attempt to domesticate animals would impose upon his liberty; a child of the wilderness, he depends on his bow or his rifle for his subsistence, and wanders free. It is not therefore surprising that no attempt should have been made by the aboriginal inhabitants to reduce the Bison to obedience. Catesby however says that these animals have been known to breed with tame cattle that were become wild, but that the calves being so too were neglected, "and though," he continues, "it is the general opinion that if reclaiming these animals were not impracticable (of which no trial has been made), to mix the breed with tame cattle would much improve the breed, yet nobody has had the curiosity nor have given themselves any trouble about it." Pennant states that the experiment has been made, and that it has failed, for he thus writes in his 'Arctic Zoology:'—"Attempts have been made to tame and domesticate the wild bison, by catching the calves and bringing them up with the common kind, in hopes of improving the breed. It has not yet been found to answer: notwithstanding they had the appearance for a time of having lost their savage nature, yet they always grew impatient of restraint, and, by reason of their great strength, would break down the strongest inclosure, and entice the tame cattle into the corn-fields. They have been known to engender together and to breed; but I cannot learn whether the species was meliorated by the intercourse."

A very fine American Bison bull was shown some years ago in this country as the 'Bonassus,' and under that name found its way into the epilogue of the Westminster Play as one of the wonders of the day. It was afterwards purchased by the Zoological Society of London; but it had been enfeebled by confinement and disease, and died soon after the Society became possessed of it. The Hudson's Bay Company supplied its place by presenting a young cow in 1829, which is still alive in the Gardens, Regent's Park (July, 1853.)

(Owen, *British Fossil Mammals and Birds*; Vasey, *Delineati[illegible] of the Ox-Tribe*; Cuvier, *Ossemens Fossiles*; A. White, *Popular History of Mammalia*; *Proceedings of Zoological Society*.)

BI'STON, a genus of Moths, belonging to the family *Geometridæ*. The principal distinguishing characters of this genus are as follows:—Palpi short and three-jointed; antennæ rather long, and distinctly pectinated in the males, each joint being furnished with a ciliated branch, and these branche[illegible]gest on the central joints (in the females these branches are wanti[illegible] nearly so); body thick; wings present in both sexes, not very thickly covered with scales, and hence slightly transparent, especially in the females. The larva has ten legs, and is elongate, cylindrical, and tuberculated, and has the head more or less notched in front; it assumes the pupa state underground at the roots of trees.

There appears to be an analogical resemblance between these moths and the *Notodontidæ*, their larvæ showing that they are not otherwise allied. The imago state of the species however may be distinguished by the different texture of the wings, and structure of the antennæ.

Three species of this genus have been discovered in this country:—*Biston prodromaria*, the Oak-Beauty; *B. betularius*, the Pepper-Moth; and *B. hirtarius*, the Brindled Beauty. The first of these has the antennæ bipectinated to the apex, and the last two have the antennæ simple at the apex in the males.

B. prodromaria has the wings of an ash-colour, or approaching to white, finely sprinkled with black: each of the upper wings has two transverse bent fasciæ of a brown colour, more or less margined with black, and the under wings have one fascia of the same description. When the wings are expanded it measures from an inch and a half to two inches in width.

The caterpillar feeds upon the oak, poplar, &c. The moth is rare, but is found in the month of March in the trunks of oak trees in the neighbourhood of London, and elsewhere.

B. betularius has received the name of Pepper-Moth from its being of a white colour, and, as it were, peppered with black almost uniformly over the wings.

This moth is about the same size as the last, and is not uncommon in the month of June in woods near London, and in other parts. Its caterpillar feeds upon the oak, willow, poplar, elm, &c.

B. hirtarius is of a brown colour, dotted with gray, with three or four transverse black bent lines on each wing, and a whitish fascia near the hinder margin. It is common among poplar and lime-trees, and is about an inch and three-quarters in expanse. In the females the wings have a greenish hue.

BISTORT. [Polygonum.]

BITTER-BLAIN. [Vandellia.]

BITTER-CRESS. [Cardamine.]

BITTER-SPAR, a name given to Magnesian Limestone. [Dolomite.]

BITTER-SWEET. [Solanum.]

BITTER-WOOD. [Xylopia.]

BITTERN, *Botaurus* (Brisson), a genus of Birds belonging to the family of Herons, or *Ardeidæ*. The following are the characters which principally distinguish the Bitterns from the rest of the family:—Bill strong, about as long as the head, compressed, and higher than it is broad; mandibles equal in length, the upper being rather the deepest, and slightly curved from the base to the point; edges of both mandibles somewhat incurved, very sharp, and finely serrated toward the point. Legs, as compared with those of others of the family, rather short. Neck also comparatively short, covered on its sides and front with long loose feathers which can be erected at pleasure, and on the back (of the neck) with down, the long loose feathers of the side meeting behind, and covering the downy part in certain attitudes, as, for example, when the bird passes through the reeds and rushes.

The Bitterns comprehended under the Prince of Canino's subgenus *Botaurus* are widely diffused, but being solitary birds, haunting wooded swamps or reedy marshes, where they generally lie hid all day, and coming forth to feed at night, they are seldom seen. There are several species of this subgenus, and of these the Night Heron or Qua-Bird (*Ardea Nycticorax*, Linnæus, *Nycticorax Europæus*, Stephens) is found both in the Old and New World. [Nycticorax.]

As an example of the subgenus, the Common Bittern or Bittour (*Botaurus Stellaris*, Steph., *Ardea Stellaris*, Linn., Uccello Lepre and Trombutto of the Italians, Rohrtrommel of the Germans, and Butor of the French) may be taken. The provincial English names of Mire-Drum, Bull of the Bog, &c., will occur to many of our readers as being indicative, in common with some of the foreign ones, of the bellowing or drumming noise for which the bird is so famous. This deep note of the 'hollow-sounding bittern' is exerted on the ground at the breeding season, about February or March. As the day declines he leaves his haunt, and rising spirally soars to a great height in the twilight. Willughby says that it performs this last-mentioned feat in the autumn, "making a singular kind of noise nothing like to lowing." Bewick says that it soars as above described when it changes its haunts. Ordinarily it flies heavily, like the heron, uttering from time to time a resounding cry, not bellowing; and then Willughby, who well describes the bellowing noise of the breeding-season, supposes it to be the night-raven, at whose 'deadly voice' the superstitious wayfarer of the night turned pale and trembled. "This, without doubt," writes Willughby, "is that bird our common people call the night-raven, and have such a dread of, imagining its cry portends no less than their death or the death of some of their near relations; for it flies in the night, answers their description of being like a flagging collar, and hath such a kind of hooping cry as they talk of." Others, with much reason, consider the Qua-Bird above mentioned (which utters a loud and most disagreeable noise while on the wing, conveying the idea of the agonies of a person attempting to vomit), to be the true night-raven.

The food of the Bittern consists for the most part, as might be suspected from its haunts, of aquatic animals. Pennant says that frogs are its principal food, adding, "not that it rejects fish, for small trouts have been taken out of its stomach."

The rude nest of the Bittern is generally formed of reeds, sticks, &c., on some 'tump,' to use Montagu's expression, in a reedy marsh or well-clothed rushy moor, and contains four or five pale green eggs. The time of incubation is about twenty-six days.

In the palmy days of falconry the Bittern afforded the best of sport. We find it mentioned in the 'flights to the field, called great flights.' "There is yet," says Tubervile, "another kinde of flight to the fielde, which is called the great flight, as to the cranes, wild geese, bustard, birde of Paradise, bittors, shovelars, hearons, and many other such like." Accordingly we find it protected by the severe penalties of the stat. 25 Hen. VIII. c. 11, confirmed by stat. 3 and 4 Edw. VI. c. 7. One year's imprisonment, and a forfeiture of eightpence for each egg, was the punishment awarded to those who destroyed or took away the eggs of the 'bittour.' When the hawk had 'bound with' the bittern and brought it down, it was the duty of the falconer to make in apace to rescue her, by plunging the bill of the bittern into the ground, to prevent injury to the hawk; for when wounded the bittern is not daunted, but lies watching his opportunity to dart his spear-like bill at his enemy as soon as he comes within his reach, and as he generally aims at the eye, he should be approached with the greatest caution. The modern sportsman should beat for these birds with pointers or very close-hunting spaniels; for they are moved with as much difficulty as a jack-snipe, and, like that bird, will often lie till they are almost trodden on, rather than take wing.

The Bittern was well known to the ancients, and there can be little doubt that it is the 'Αστερίας ('Ερωδιός), of Aristotle. ('Hist. Anim.' book ix. c. xviii.) In the same chapter its sluggishness and the fable of its origin from slaves metamorphosed into birds are mentioned. Aristotle observes further that the Φώυξ especially strikes at the eyes; and in the edition of Belon (1557), 'enrichy de quatrains,' we find the following verse below the figure of the 'butor:'—

> "En un Butor Phoix, pour sa paresse
> Fut par les dieux changé divinement.
> Un paresseux aussi communement
> Est dit Butor, pour son peu d'alegresse."

The flesh of the Bittern was formerly in high esteem (in the reign of Henry VIII. it was valued at a shilling), nor is it despised in the present day; when well fed, its flavour somewhat resembles that of the hare, nor is it rank and fishy, like that of some of its congeners. The long claw of the hind toe is much prized as a tooth-pick, and in the olden time it was thought to have the property of preserving the teeth.

Common Bittern (*Botaurus stellaris*).

A paragraph in the last edition of Pennant, signed J. L., written probably by Latham, states that this bird "is said to inhabit the greater part of Africa; and is certainly found on the coast of Barbary, at the Cape of Good Hope, and also in India and China." Selby observes that its geographical distribution "seems confined to Europe, extending nearly to the confines of Asia;" but it was in the collection formed in the neighbourhood of Trebizond by Keith E. Abbott, Esq., and presented to the Zoological Society by that gentleman. Colonel Sykes notes it as rare in Dukkun (Deccan), and Mr. Gould as inhabiting the three continents of the Old World. In England inclosure and drainage have made the Bittern a very scarce bird, and its capture is no longer an ordinary event.

In size the Common Bittern is less than the Common Heron, being about 2¼ feet in length. The bill is about 4 inches long, brown above, greenish below; irides yellow; feathers on the crown black, shot with green, those of the hinder part of the head, neck, and breast long and loose; general colour of the plumage dull pale yellow, variegated with spots and bars of black; tail short; legs moderate, pale-green; toes and claws long and slender, middle claw serrated on the inner edge, most probably to aid it in securing its slippery prey.

B. minutus, the Little Bittern, is also a summer inhabitant of Great Britain, and is the smallest British example of the family to which it belongs. It is a native of the southern parts of Europe, the south-western parts of Asia, and probably of Africa generally. It has been killed as far north as Sweden. It is found occasionally in Germany, and is not uncommon in Holland, and occurs in France, Provence, and Italy.

B. lentiginosus, the American Bittern, is not quite so large as the Common Bittern. It is a common bird in America from Hudson's Bay to Carolina. It has different names in the various states, such as Indian Billet, Indian Hen, and Dunkadoo. In its habits and voice it is very like the Common Bittern. It has been shot several times in Great Britain; first at Piddleton, in Dorsetshire, in 1804, and since then in several other parts of the country.

(Yarrell, *British Birds*; Thompson, *Birds of Ireland*.)

BITU'MEN, a Latin word used by Tacitus, Pliny, and other Roman writers. A considerable number of combustible mineral substances are sometimes arranged under the head of Bitumens; but their properties vary greatly in some respects, as, for example, with regard to solidity, fluidity, and colour. The term Bitumen is however usually applied to two varieties, namely, *Asphaltum* [ASPHALTUM], and a softer kind called *Elastic Bitumen*, which we shall now describe.

Elastic Bitumen, sometimes called Fossil Caoutchouc, is a rare mineral product, which has hitherto been found in three places only: 1st, in the Odin mine, near Castleton in Derbyshire, in a Secondary Limestone, accompanied by asphaltum, calcareous spar, fluor, blende, galena, and pyrites; 2nd, in a coal-mine of Montrelais, a few leagues from Angers in France, it occurs among quartz and calcareous crystals, in the veins of grit of the Coal Formation; 3rd, in a coal-mine near South Bury in Massachussets, United States.

Elastic Bitumen possesses the following characters:—It is brown, or blackish brown, and translucent in small portions; it is soft and elastic like caoutchouc, but sometimes it is as hard as leather: it has the property, like caoutchouc, of effacing pencil-marks. Its density varies from 0·9053 to 1·233. It fuses readily, and at a higher temperature it takes fire and burns with a sooty flame: it sometimes leaves one-fifth of its weight of ashes, composed chiefly of silica and peroxide of iron. If the Derbyshire Elastic Bitumen be subjected to distillation, it yields acidulous water and volatile oil, resembling that of naphtha in smell: the oil is neither acid nor alkaline, slightly soluble in alcohol, but readily so in ether; after the distillation of the water and oil, a brown viscid mass remains in the retort, which is insoluble in water or alcohol, but is dissolved by ether and by potash. If the distillation be longer continued, an empyreumatic oil resembling that of amber is obtained, and a black shining coal remains.

When the Elastic Bitumen of Montrelais is similarly treated, there is obtained a yellow bitter fetid oil, which is lighter than water and insoluble in alcohol, but it dissolves in the alkalies.

Elastic Bitumen swells when put into oil of turpentine or of petroleum; ether and oil of turpentine when boiling extract a kind of soft resin from the English and French bitumen, and this remains after the evaporation of the solvent: this resin is of a brownish-yellow colour, is bitter and inelastic; its weight is nearly half that of the bitumen employed.

It is but slightly soluble in alcohol, but readily in potash; it is inflammable, and burns with a smell of petroleum; that portion of the bitumen which is insoluble in the ether and oil of turpentine, is a grayish dry mass, resembling paper; it burns with difficulty, and carbonises; potash dissolves only a part of it. If after separating these two principles they are mixed together, the bitumen does not regain its elasticity.

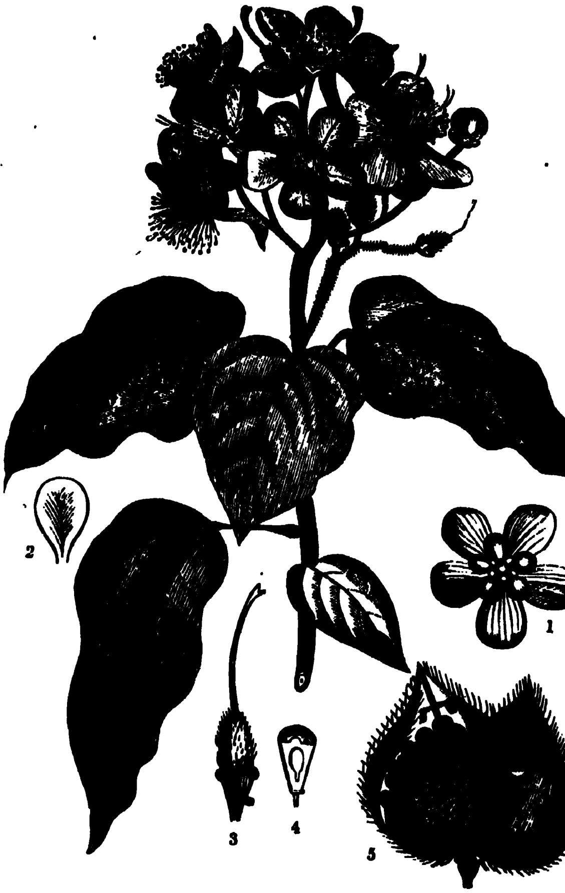
Concentrated sulphuric acid does not act upon Elastic Bitumen; but when long boiled with nitric acid it yields resin, tannin, and a little nitroperic acid. According to the analysis of M. Henry, jun., the Elastic Bitumen consists of

	English.	French.
Carbon	52·250	58·260
Hydrogen	7·496	4·890
Nitrogen	0·154	0·104
Oxygen	40·100	36·746
	1[illegible]00	100·000

Berzelius remarks that the difference [illegible] quantity of hydrogen in these specimens is so considerable, that it is surprising their properties are not more dissimilar. [NAPHTHA; PETROLEUM.]

BIVALVE, a name applied to those forms of Shell-Fish which have two shells or valves in contradistinction to those which have one shell, and which are called *Univalve*. [MOLLUSCA.] Before the structure of the Invertebrate Animals was as well known as it is at the present day, the Barnacles and Sea Acorns, which have several external valves or shells, were referred to the *Mollusca*, under the name of *Multivalves*.

BIXA, a West Indian genus of plants belonging to the natural order *Flacourtiaceæ*. It produces the substance called Arnotto. The only species of any general interest in the genus is the *Bixa Orellana*, a native of the Malayan Archipelago, but now extremely common in the West Indies, where it is cultivated in rich moist soil by the sides of rivers.



Bixa Orellana.

1, A flower seen from beneath; 2, a petal; 3, an ovary with style and stigma; 4, a seed cut vertically, showing the embryo; 5, a ripe fruit.

This plant forms a small tree with deep-green shining heart-shaped leaves, and clusters of purplish flowers, which are succeeded by capsules of a heart-shaped form, covered with stiffish bristles, and opening into two valves which contain, attached to their middle, a number of seeds covered with a soft, sticky, vermilion-coloured rind. It is the latter which furnishes the arnotto of commerce. According to Fée, this substance is obtained by heaping up the seeds in water for several weeks or months, and afterwards pressing them, when the colouring matter separates and is afterwards precipitated in the water. Or the pulp is separated by washing and maceration, and the colouring matter precipitated by the aid of an acid, and caught upon fine sieves. Independently of the use of arnotto for staining cheese and butter, the Indians paint their persons with it, and thus, it is said, destroy the subcutaneous vermin with which they are infested. It acts as a purgative taken internally; but its reputed powers as an antidote to the poison of the cassava are imaginary.

BIXINEÆ, a natural order of plants named after the genus *Bixa*. The genus *Bixa* and its allies are now placed in the natural order *Flaicourtiaceæ*. [FLACOURTIACEÆ.]

BLACKBERRY. [RUBUS.]

BLACKBIRD, the English name for the well-known native songster, *Merula vulgaris* of Ray, *Turdus Merula* of Linnæus, the Schwarz-Drossel and Schwarze-Amsel of the Germans, Merle of the French, Merla and Merlo of the Italians, and *Κόττυφος* or *Κόσσυφος* of the ancient Greeks.

The Blackbird is too well known to require a description, but a word or two on the subject of its habits may not be misplaced. There are not wanting those who praise the song-thrush at the expense of the blackbird, alleging that, though the former commits depredation in our fruit-gardens in summer, it makes amends by its destruction of the shell-snails (*Helix aspersa* and *H. nemoralis*); whereas the blackbird is a most notorious fruit-eater, without any such redeeming quality. That the thrush does this service is most true, but it is not less true that the blackbird is particularly fond of the shell-snails, which it devours in the same way as the thrush. In truth, small slugs and shell-snails, to use the expression of a garden labourer, form "the chief of its living," while the thrush is equally fond of fruit in the season; but the plumage of the thrush is in its favour, and it is often pecking away at the fruit without being seen. When disturbed it glides away without noise; but the blackbird's sharp cry of alarm as it escapes generally strikes the ear, if its black coat and yellow bill have not arrested the eye. Thus much in justice to the blackbirds, for we know of instances where a war of extermination has been waged against them while the thrushes have been held sacred.

Early in the spring the Blackbird begins to build its nest. A thick-set hedge-row, an insulated close bush, a low ivied tree, are all favourite places. Moss, small sticks, root-fibres, are the materials, with an internal coat of mud-plaster, over which is a lining of fine dry grass. Four or five eggs of a bluish-green, variegated with darker markings, are here deposited. Aristotle (book v. c. 13) observes that it lays twice, and Buffon says that the first deposit ranges from five to six eggs, but the second only from four to five. The early season at which it begins to lay is often so cold as to destroy the first brood; moreover, the leafless state of the hedge or bush at that period makes the nest an easy prey to the school-boy.

The Blackbird is in general shy, but there are exceptions to the remark, as is proved by the following statement. In the spring of 1834 a pair of blackbirds built their nest in a faggot-pile close to the door of a kitchen-garden in the parish of Sunbury, Middlesex, where the garden-labourers were passing all day long wheeling manure into the garden, &c. The nest was built among some dead thorns, there piled up, so low that the passer-by could look into it, and was very much exposed; but the parents, notwithstanding the curiosity of spectators, brought up their nestlings. This was a late brood; and as many early nests had been taken in the neighbouring hedge-rows, it is not impossible that the birds, disappointed of their first brood, might have been driven to choose a spot nearer the house for security.

Albinos sometimes occur among these birds. Several instances are recorded: the following is from 'Loudon's Magazine' (No. 43, p. 596):—"In 1829 a blackbird's nest, containing four or five young ones, was found at Rougham, near Bury St. Edmunds, Suffolk. One of the young ones differed in colour materially from the rest. Its eyes were red, its bill was yellow (which is not usual in very young blackbirds). The nest was not taken till the young were fully fledged. On attempting to capture them, two or three made their escape; the white one was safely caught. The red-eyed bird afterwards became nearly or wholly white, and it still retains this colour." In the British Museum there is a female of a dusky white or cream-colour with Yorkshire for its locality. Other instances are recorded.

Bechstein, in his work on Cage-Birds, says, "The white variety is very well known; there is besides the streaked, the black with a white head, and the pearl-gray." The same author gives the following account of the musical properties of the Blackbird in confinement:—"Its voice is so strong and clear that in a city it may be heard from one end of a long street to the other. Its memory is so good that it retains without mixing them several airs at once, and it will even repeat little sentences. It is a great favourite with the lovers of a plaintive, clear, and musical song, and may in these respects be preferred to the bullfinch, whose voice is softer, more flute-like, but also more melancholy. The price of these two birds, if well taught, is about the same."

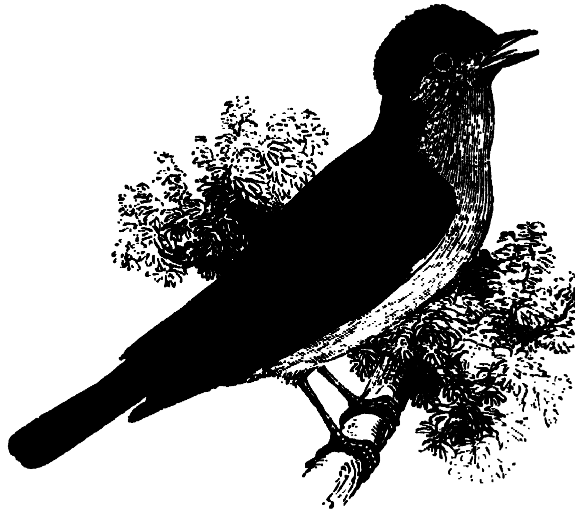
Turdus torquatus is called the Ring-Blackbird. [TURDUS.]

BLACK-BONNET, one of the names of the Reed Bunting. [EMBERIZA.]

BLACK-CAP, the common English name for the Black-Cap Warbler, Der Mönch of the Germans, Fauvette à Tête Noire of the French, Caponera Gentile of the Italians, *Atricapilla* of Aldrovandus, *Curruca atricapilla* of Brisson, *Motacilla atricapilla* and *Motacilla moschita* of Gmelin (the latter being the female), *Sylvia atricapilla* of Latham and of Bechstein, and *Curruca atricapilla* of Gould ('Birds of Europe').

"Of all the birds," says Sweet, "that reside in or visit the British Islands there is none that can come up to the present for song except the nightingale, and by some persons it is more admired than even that bird. Its arrival in this country is generally about the first week in April, and the earliest that I ever saw was on the 25th of March. They leave us again about the end of September, sometimes a straggling one may be seen at the beginning of October; the latest I ever saw in a wild state was on the 15th of that month. When it first arrives in this country its chief food is the early ripened berries of the ivy, and where those are there the black-caps are first to be heard singing their melodious and varied song. By the time the ivy-berries are over the little green larvæ of the small moths will be getting plentiful, rolled up in the young shoots and leaves; this then is their chief food until the strawberries and cherries become ripe; after that there is no want of fruit or berries till their return, and there is no sort of fruit or berry that is eatable or wholesome that they will refuse. After they have cleared the elder-berries in autumn they immediately leave us."

Nor is Sweet singular in his eulogy. All agree in praising its melody. In Norfolk and in other places in Great Britain it is called the Mock Nightingale, and indeed, like the nightingale, it continues its song far into the night. Bechstein, who has paid so much attention to the song of birds, says that it rivals the nightingale, and that many persons even give it the preference. "If," adds that author, "it has less volume, strength, and expression, it is more pure, easy, and flute-like in its tones, and its song is perhaps more varied, smooth, and delicate."



Black-Cap (*Curruca atricapilla*), male.

This fruit-eating warbler is one of the *Ficedulæ* so much prized under the name of Beccafico, though, as Bechstein well observes, every taste but that of the palate must be destroyed if this charming bird is caught for the table. [BECCAFICO.] Its fondness for ivy-berries seems to have been noticed in Italy, where it is permanent, and thence probably is derived one of its Italian names, Caponera d'Edera. The difference of plumage in the males and females, and in the young birds, which resemble the females, may possibly throw some light on the opinion which Willughby thus mentions :—"The ancients report," writes Willughby, "that the black-caps (*Atricapillæ*) in the beginning of autumn are changed into Ficedulæ and Beccaficos by the mutation of their voice and colour; from whom, till I be assured by experience, I must crave leave to dissent."

There can be little doubt that Willughby had in his mind that passage in the 49th chapter of the 9th book of Aristotle where the latter, speaking of the changes of birds, states that the Beccaficos (Συκαλίδες) and the Black-Caps (Μελαγκόρυφοι) are changed into each other. Indeed Willughby thus heads his chapter on the Black-Cap :—"The Black-Cap: *Atricapilla seu Ficedul*[illegible] Aldrov.; called by the Greeks Συκαλìs et Μελαγκόρυφος; by the Italians Capo Negro." The passage in Aristotle may be thus freely translated :—

"And in like manner beccaficos and black-caps, for these too are changed into each other. The bird is a beccafico at the commencement of autumn and a black-cap at the decline of that season, and the only difference is in their plumage and their voice. That they are the same birds may be seen by observing them before the change is complete, and when they are neither one nor the other."

Pliny too appears to have had this passage in his view, though he does not acknowledge it, when he wrote (lib. x. cap. 29) :—"Alia ratio ficedulis. Nam formam simul coloremque mutant. Hoc nomen non nisi autumno habent, postea melancoryphi vocantur."

Belon (ed. 1555, folio) makes the Bulfinch the Συκαλìs and Μελαγκόρυφος of the Greeks, and Beccafighi of the Italians, naming it also *Atricapilla;* but in a subsequent edition, 'enrichy de Quatrains' (small 4to. 1557), the Greek, Latin, and Italian names, identifying it as a *Ficedula*, as well as the name *Atricapilla*, are omitted; and the bird appears with the provincial synonyms of the Bulfinch. In other instances, in that of the very next bird for example, the Greek and Latin names given in the folio edition are retained.

Upon the whole, there is reason for coming to the conclusion that our Black-Cap is the bird alluded to by Aristotle. Ray seems to have been of this opinion, for he thus records it in his 'Synopsis' :—"*Atricapilla sive Ficedula*, Aldrov.; Συκαλìs et Μελαγκόρυφος, Græcis; the Black-Cap."

It occurs frequently in the greater portion of Europe, through the northern and eastern parts of which it is widely diffused. Temminck says that it is rare beyond the Apennines and Pyrenees. C. Bonaparte notes it as permanent and common near Rome. It visits the southern coasts of England, from Sussex to the Land's End. It visits Wales, and has been taken in the north of Ireland. It visits also Suffolk and Norfolk, and the northern counties of England. It is a summer visitor in Denmark, Norway, Sweden, and Lapland.

The male Black-Cap is nearly 6 inches in length, and about 4½ drachms in weight. Upper part of the head black; back of the neck ashy brown; upper parts of the body gray, with a greenish tinge; quills and tail dusky, edged with dull green; breast and belly light ash-colour; legs and feet bluish-gray, or lead-colour; bill brown; irides dark hazel.

The female is of larger size; the crown of the head is of an umber-brown or rust-colour; and the plumage generally is darker, and more inclining to greenish than it is in the male.

The plumage of the young when they leave the nest resembles that of the female.

Gardens, orchards, and thick hedges are the favourite haunts of the Black-Cap; and there, among brambles and nettles, or in some low bush, its nest is built. Dry stalks of goose-grass and a little wool, lined with fibrous roots, and frequently with a few long hairs, with now and then a little moss on the outside, form the structure. Four or five, sometimes six eggs of a reddish-brown, weighing about 35 grains, mottled with a darker colour, and sometimes dotted with a few ashy specks, are then deposited. Pennant speaks of a nest which he discovered in a spruce fir. Temminck mentions the hawthorn-bush as the most frequent place.

The Black-Cap in a state of nature is with difficulty seen when singing, at which time it seems to take pains to secrete itself. White however, who saw it in this act, says that while warbling the throat is wonderfully distended.

In captivity it seems to be a great favourite not only from its song but from its attractive qualities. Even in a state of nature it is a mocking bird, and when caged it soon learns the notes of the nightingale and canary. The female is also, but in a limited degree, a songster.

Bechstein speaks of the striking affection which it shows for its mistress :—"It utters a particular sound, a more tender note to welcome her; at her approach he darts against the wires of his cage, and by a continued fluttering, accompanied with little cries, he seems to express his eagerness and gratitude. A young male, which I had put in the hot-house for the winter, was accustomed to receive from my hand every time I entered a meal-worm; this took place so regularly, that immediately on my arrival he placed himself near the little jar where I kept the meal-worms. If I pretended not to notice this signal, he would take flight, and, passing close under my nose, immediately resume his post; and this he repeated, sometimes even striking me with his wing, till I satisfied his wishes and impatience."

BLACK-COCK, one of the English names for the Heath-Cock, the male of the Black Game or Black Grouse; the Birk-Hahn of the Germans; Coq de Bruyère à Queue Fourchue, Coq de Bois, and Faisan Bruyant (Belon), of the French; Gallo di Monte, Gallo Cedrone, Gallo Selvatico, Gallo Alpestre, Fasan Negro, and Fasiano Alpestre of the Italians; Orrfugl of the Norwegians; *Tetrao seu Urogallus minor* of Willughby and Ray; *Tetrao tetrix* of Linnæus; and *Lyrurus tetrix* of Swainson. The female is called a Gray Hen, and the young are named Poults,* a term which is applied to the Black Game generally on the borders of Hampshire and Dorsetshire.

This noble bird, whose plumage when in full beauty has defied all pencils save that of Edwin Landseer, the only painter who has given a true idea of it, is now the largest of its race in the British Islands, of whose fauna it is one of the principal ornaments. It is, says Temminck, more widely diffused over the central parts of Europe than the Capercailzie (*Tetrao Urogallus*, Pennant); or the Rakkelhan (*Tetrao medius*, Meyer). In Germany, France, and Holland it is tolerably plentiful: in the northern countries, such as Denmark, Sweden, Norway, and Russia it abounds.

Of the southern counties of England, Hampshire, Dorsetshire, Somersetshire, and Devonshire possess it, and now and then it is seen in the heathy parts of Sussex and Surrey. In the New Forest, and the wild heaths on the borders of Hampshire and Dorsetshire, in the neighbourhood of Wimborne, it is perhaps more common than it is anywhere else in the south. The Quantocks, and some other uncultivated tracts in Somersetshire, and Dartmoor and Sedgemoor in Devonshire are its head-quarters in those counties; but it is comparatively rare.

Staffordshire has it sparingly, and Northumberland plentifully.

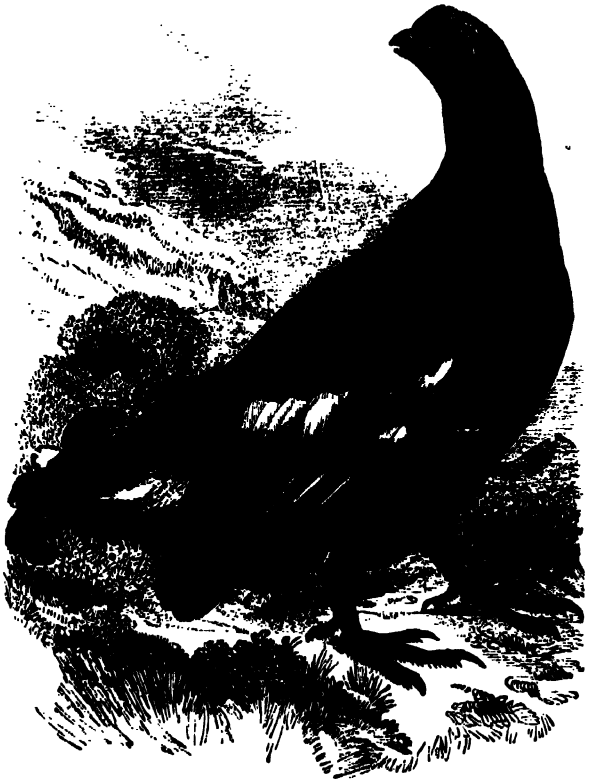
In the Highlands of Scotland the Black-Cock is abundant, and it is found in some of the Hebrides. In North Wales it occurs sparingly, where it is strictly preserved.

The following account of the haunts and habits of the Black-Cock is from the pen of Mr. Selby :—

"The bases of the hills in heathy and mountainous districts, which are covered with a natural growth of birch, alder, and willow, and intersected by morasses clothed with long and coarse herbage, as well as the deep and wooded glens so frequently occurring in extensive wastes, are the situations best suited to the habits of these birds, and most favourable to their increase. During the months of autumn and winter the males associate, and live in flocks, but separate in March or April; and, being polygamous, each individual chooses some particular station, from whence he drives all intruders, and for the possession of which, when they are numerous, desperate contests often take place. At this station he continues every morning during the pairing season (beginning at day-break) to repeat his call of invitation to the other sex, displaying a variety of attitudes, not unlike those of a turkey-cock, accompanied by a crowing note, and one similar to the noise made by the whetting of a scythe. At this season his plumage exhibits the richest glosses, and the red skin of his eyebrows assumes a superior intensity of colour. With the cause that urged their temporary separation their animosity ceases, and the male birds again associate and live harmoniously together. The female deposits her eggs in May; they are from six to ten in number, of a yellowish-gray colour, blotched with reddish-brown. The nest is of most artless construction, being composed of a few dried stems of grass placed on the ground, under the shelter of a tall tuft or low bush, and generally in marshy spots where long and coarse grasses abound. The young of both sexes at first resemble each other, and their plumage is that of the hen, with whom they continue till the autumnal moult takes place; at this time the males acquire the garb of the adult bird, and quitting their female parent join the societies of their own sex. The food of the black grouse, during the summer, chiefly consists of the seeds of some species of *Juncus*, the tender shoots of heath and insects. In autumn the Crowberry or Crawcrook (*Empetrum nigrum*), the Cranberry (*Vaccinium oxycoccos*), the Whortleberry (*Vaccinium Vitis Idæa*), and the Trailing Arbutus (*Arctoctaphylos Uva Ursi*), afford it a plentiful subsistence. In winter, and during severe and snowy weather, it eats the tops and buds of the birch and alder, as well as the embryo shoots of the fir tribe, which it is well enabled to obtain, as it is capable of perching upon trees without difficulty. At this season of the year, in situations where arable land is interspersed with the wild tracts it inhabits, descending into the stubble grounds, it feeds on grain."

---

* This is an old name for the Black Game. Thus Turbevile (1611) writes, "If your goshawke be once a good partridger, beware that you let her not flee the pout or the feasant."

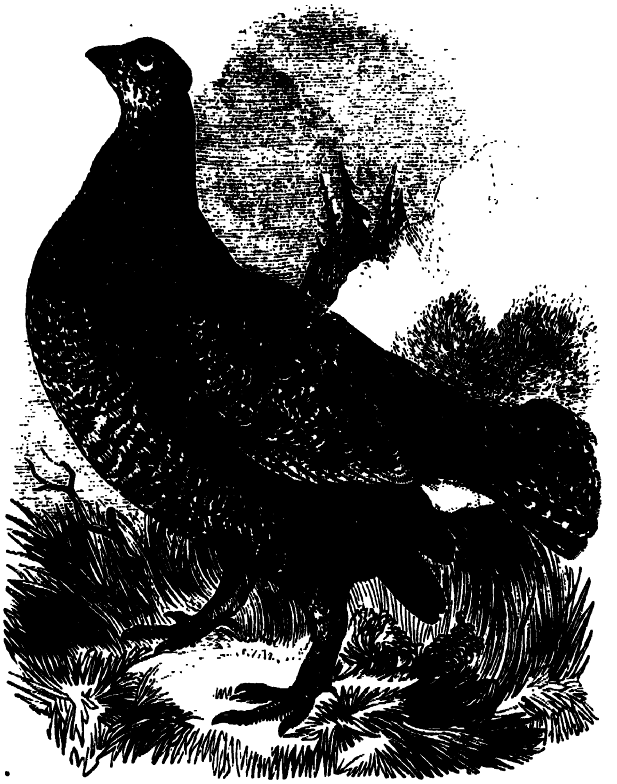


Black-Cock (*Tetrao tetrix*).

Linnæus says that the young are brought up upon gnats.

That the Black-Cock was known to the ancients there is little doubt. Aristotle, in the first chapter of his 6th book, where he is speaking of the nidification of birds, says that "Those which are not strong of flight, such as partridges and quails, do not lay in nests (properly so called) but on the ground, merely collecting together materials (ὕλην): so also do the larks (κόρυδες) and the tetrix." At the end of the chapter he says, "But the Tetrix, which the Athenians call Ourax, neither makes its nest upon the bare ground nor yet upon trees, but upon low plants (ἐπὶ τοῖς χαμαιζήλοις φυτοῖς):" answering to Temminck's description—"niche dans les bruyères ou dans les buissons:" to Selby's—"under the shelter of a tall tuft or low bush, generally where long and coarse grasses abound:" and to Graves's—"on any dry grass or heath, without any appearance of a nest, but most generally in the midst of a high tuft of heath." This Tetrix, then, which the Athenians called Ourax, was not improbably our Black-Cock.

Pliny's description (cap. xxii. lib. x.)—"Decet tetraonas suus nitor absolutaque nigritia, in superciliis cocci rubor"—looks very like our bird, though the passage occurs in his chapter on Geese, and so it struck Belon. The tetraones mentioned in company with the peacocks, guinea-fowls, and pheasants, in chap. xii. of Suetonius (in 'Calig.') were probably the same.



Gray Hen (*Tetrao tetrix*), female.

The flesh of the Black Grouse is much esteemed. The different colour of the flesh of the pectoral muscles must have struck every one. The internal layer, which is remarkably white, is esteemed the most delicate portion. Belon goes so far as to say that the three pectoral muscles have three different flavours: the first that of beef, the next that of partridge, and the third that of pheasant.

Male.—Weight of a fine specimen about 4 pounds; bill dusky black; irides hazel; head, neck, breast, back, and rump glossy black, shot with steel-blue and purple; eye-brows naked, granulated, and of a bright vermilion red; belly, wing-coverts, and tail pitch black; secondaries tipped with pure white, and forming with the neighbouring coverts a band across each wing; under tail-coverts pure white; legs furnished with hair-like feathers of a dark-brown, speckled with gray; toes pectinated; tail black—the exterior feathers bend outwards, and are much longer than those in the middle: this arrangement gives the singular curvature and forked shape to the tail which distinguishes the bird.

Female.—Weight about 2 pounds; general colour ferruginous, barred and mottled with black above, paler below, with dusky and brown bars; under tail-coverts white, streaked with black; tail orange-brown, speckled with black, showing a slight disposition to be forked, tipped with grayish white.

No person is permitted to kill, destroy, carry, sell, buy, or have in his possession, any Heath-Fowl, commonly called Black Game, between the 10th of December and 20th of August. The limitation in the New Forest, Somerset, and Devon is greater, being from the 10th of December to the 1st of September.

Hybrids.

Several well-authenticated instances have occurred of hybrids bred between the Common Pheasant and the Gray Hen. White, in his 'History of Selborne,' gives an account of a bird, of which the Hon. and Rev. W. Herbert says, in a note to White's 'Selborne,' 1833, "I saw this curious bird stuffed in the collection of the Earl of Egremont at Petworth, and I have not the slightest hesitation in pronouncing that it was a mule, between the black cock and the common pheasant. I did not entertain the slightest doubt on the subject: Mr. Markwick's suggestion that the bird may be an old pea-hen is very weak. He might as well have said an ostrich. Neither in size, shape, nor colour had the bird the least affinity to a pea-fowl. I can also most positively assert that this bird was not, as suggested in a note (p. 343), a hen pheasant with the feathers of a cock. Such birds are well known to me, and it noways resembled them. To Mr. White's description of the bird above, where he says that the back, wing-feathers, and tail were somewhat like the upper parts of a hen partridge, I scratched out at the time the words 'somewhat like,' and wrote in the margin 'much browner than,' and with that correction I believe Mr. White's description to be quite correct."

Notwithstanding Mr. Herbert's opinion, Mr. Yarrell has stated his conviction that the hybrid grouse of White's 'Natural History of Selborne' to be a young Black-Cock having nearly completed his first moult.

Of undoubted cases of hybrids arising from a mixture with the Gray Hen, the following are related.

At a meeting of the Zoological Society on the 24th of June, 1834, Mr. Sabine called the attention of the meeting to a specimen of a hybrid bird between the Common Pheasant (*Phasianus Colchicus*, Linn.) and the Gray Hen (*Tetrao tetrix*, Linn.), which was exhibited. Its legs were partially feathered; it bore on the shoulder a white spot; and its middle tail-feathers were lengthened. Mr. Sabine stated his intention of entering at some length into the history of hybrid and cross animals in connection with his description of this bird, which was bred in Cornwall. This bird was a male.

On the 12th of May, 1835, at a meeting of the same society was read 'Some Account of a Hybrid Bird between the Cock Pheasant (*Phasianus Colchicus*, Linn.) and Gray Hen (*Tetrao tetrix*, Linn.), by Thomas C. Eyton, Esq.' This paper was illustrated by the exhibition of the preserved skin of the bird, and also of a drawing made from it.

The subjoined table shows some comparative measurements between the hybrid bird in question (the Cock Pheasant) and the Gray Hen:—

	Gray Hen		Hybrid Bird, female.		Male Pheasant.	
	Ft.	In.	Ft.	In.	Ft.	In.
Length of the tarsus	0	2 3/10	0	2 3/4	0	3 1/10
Length of the middle toe	0	2 1/10	0	2 1/2	0	2 2/10
Expansion of the wings	2	0	2	2	2	4 1/2
Length of the middle tail-feathers . . .	0	4	0	7 1/2	1	7
Length of the intestinal canal from vent to gizzard	4	2	3	5 1/2	4	0
Length from the vent to the cæca . . .	0	6	0	5 1/2	0	4 1/2
Length of the cæca	2	0	2	0	0	8 1/2

The late Mr. W. Thompson, of Belfast, has also described a hybrid of this kind that was shot in Wigtonshire ('Mag. Zool. and Bot.' vol. i.). Mr. Yarrell, in the second volume of his 'British Birds,' has also recorded other instances.

BLACK FISH. [CENTROLOPHUS.]

BLACK JACK, the name given by miners to the Sulphuret of Zinc. [ZINC.]

BLACK-THORN. [PRUNUS.]

BLADDER, or *Vesica Urinaria*, so called to distinguish it from the Gall-Bladder, is a musculo-membranous bag or pouch, which serves as a temporary reservoir for the urine; it communicates with the kidneys by means of the ureters, and opens externally by means of the urethra.

The urinary apparatus is confined to the red-blooded classes of animals, all of which have kidneys, whilst some orders and genera have no urinary bladder. In quadrupeds the bladder is of a pyriform shape, and is completely surrounded by the peritonæum or serous lining of the abdomen; and it may be taken as a general rule that it is smaller, stronger, and more muscular in carnivorous than in graminivorous animals; in the latter it is almost membranous, and in some of them is particularly large.

In the whole class of birds there is no urinary bladder, and the ureters open into the cloaca, a musculo-membranous bag, which takes the place of the rectum, bladder, and uterus, and serves as a reservoir for the solid excrements, the urine, and eggs. The urine in these animals dilutes the fæces, and deposits the carbonate of lime which constitutes the basis of the shell. The urinary bladder exists in several genera and species of fishes.

In the human subject the urinary bladder is placed in the pelvis or basin immediately behind the symphysis pubis, and before the rectum, or terminal portion of the intestines, in the male; but it is separated from it in the female by the uterus and vagina. Its form and relations vary according to the age of the individual. In infancy it is of a pyriform shape, and is contained almost entirely in the abdomen, thus resembling its permanent condition in quadrupeds. At this period it may be considered as consisting of three portions; the narrow tapering part, or neck, the upper rounded portion, or fundus (sometimes called summit), and the intermediate portion, or body; but as the pelvis expands the bladder gradually subsides into it, and undergoes a remarkable change of form. Thus, in the adult its figure is that of a short oval, compressed at the fore and back part; its lower surface subsides on the rectum, and expanding forms what is termed by anatomists the bas fond of the bladder. This change of form is dependent not only upon the enlargement of the cavity in which the bladder is contained, but also upon the weight of the fluid which it habitually sustains, and thus in advanced age it is more deeply sunk in the pelvis than in the middle periods of life. In the female its transverse diameter is greater than in the male, in consequence of the antero-posterior diameter of the pelvis being encroached upon by the uterus. Its capacity varies in the different periods of life; and as a general rule it may be said to increase in proportion as the individual advances in years, and to be greater in females than in males. Its capacity is modified in different individuals by their habits and the natural exercise of its functions. It is more particularly changed by disease; thus, from the effects of long-continued irritation it may be reduced to such a state that it will not contain more than a few drops of urine; and, on the contrary, when from any cause its contents cannot be duly evacuated, it may be distended so as to contain many quarts of urine, and occupy a large proportion of the abdomen. Its ordinary capacity may be estimated at a pint and a half.

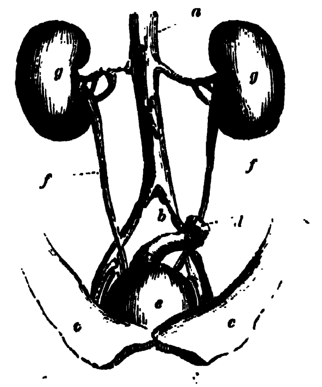


Fig. 1.—The Ureters, running from the kidneys to the bladder.

a, Aorta; *b*, bifurcation; *c*, abdominal muscles turned down; *d*, the rectum cut and tied; *e*, bladder; *f f*, ureters; *g g*, kidneys.

The neck or constricted portion of the bladder is compared to a truncated cone, longer at the sides and below than above. In infancy, owing to the position of the bladder, its direction is oblique; for a similar reason it is horizontal in the adult; it differs in structure from the rest of the organ. The neck, which is formed of a somewhat fibrous whitish substance, is the connecting medium between the bladder and the urethra. Its posterior part rests on the rectum; its anterior is surrounded, at least below and at the sides, by the prostate gland, which is peculiar to the male, and is composed of an aggregation of mucous follicles, disposed so as to form three lobes, one on each side of the neck of the bladder, and one below called the middle lobe, which forms a slight projection into the opening of the urethra.

The bladder, like the other hollow viscera, is composed of three layers, or coats, united to each other by cellular tissue; these coats are the peritonæal or serous, the muscular, and the mucous. The peritonæal coat has been already described as investing only a portion of the organ; it is united to the muscular coat by cellular tissue, which is extended over the whole of the latter, being however thinner under the peritonæal coat than elsewhere. The muscular coat has been described by some anatomists as a distinct muscle under the name of detrusor urinæ; it is composed of pale fibres interlacing in all directions. Three distinct layers have been described, but it is sufficient for all useful purposes to say, that the superficial fibres are directed in the course of the axis of the bladder; that at the sides they are more and more oblique; and that the more internal fibres assume a circular direction as they approach the neck of the bladder, so that some anatomists have described them in this part as a distinct muscle, under the name of sphincter vesicæ. This reticulated structure of the muscular coat enables the bladder to contract so perfectly as to expel every drop of its contents.

When the bladder is much distended, the muscular coat becomes attenuated to such a degree, that it is difficult to distinguish it from cellular tissue. Sometimes its fibres become so much enlarged from the effects of long-continued irritation and overaction of the organ, that they form projecting lines or columns under the mucous coat; this appearance of the bladder is dessignated by the French Vessie à Colonnes. The mucous membrane is occasionally protruded between these columns, forming sacs, or pouches, in which urinary calculi are sometimes lodged; these calculi are then said to be encysted or sacculated. The muscular coat is united to the third, last, or mucous coat by a distinct layer of cellular tissue, to which the term nervous or vascular coat is sometimes improperly applied. The mucous coat, or lining of the bladder, belongs to that division of the mucous membranes denominated genito-urinary; it not only lines the bladder, but is prolonged upwards along the ureters into the kidneys, and downwards along the urethra; it is of a pale rose-colour, is smooth when the bladder is distended, and corrugated when it is empty; it secretes a viscid fluid termed mucus, which protects it from the acrimony of the fluid with which it is constantly in contact. Three openings are seen in it; two situated posteriorly, about an inch and a half from each other, which are the openings of the ureters, and one anteriorly, which is the opening of the urethra. Extending from the openings of the ureters to that of the urethra are observed two prominent lines, which are formed by muscular fibres elevating the mucous coat; these lines form the sides of a triangle, the base of which is an imaginary line drawn between the openings of the ureters the apex is at the urethra. The space thus marked out is denominated the trigone vesicale; it is paler than the rest of the internal surface of the bladder, is possessed of peculiar sensibility, and is smooth in the contracted as well as in the distended condition of the bladder.

The two prominent lines which form the sides of the trigone vesicale, according to Sir C. Bell, are distinct muscles, the muscles of the ureters. They have their fixed point or origin at that prominence or tubercle existing at the inferior surface of the urethra, which has been already described as formed by the middle lobe of the prostate, their insertion or moveable point being at the opening of the ureters. Their use is to assist in the contractions of the bladder, to support and close the mouths of the ureters, and to preserve the obliquity of these canals by drawing them down during the contractions of the bladder. The tubercle whence these muscles are supposed to take their origin is termed the luette or uvula vesicæ; but these terms are more particularly applicable to it when enlarged and diseased. It then forms a prominent tumour at the orifice of the urethra, acts the part of a valve, and becomes a troublesome cause of retention of urine.

The arteries of the bladder are derived from the internal iliac and its branches; its veins empty themselves into the internal iliac vein; these vessels are most abundant about its neck and bas fond. The lymphatics follow the course of these vessels. The nerves are of two kinds, the one derived from the sacral plexus of the cerebro-spinal system, the nerves of animal life; the other derived from the hypogastric plexus of the sympathetic, the nerves of organic life.

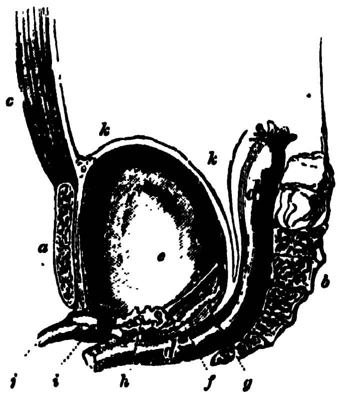

Fig. 2.—Side view of the Bladder of an adult male.

a, Pubes; *b*, sacrum; *c*, recti muscles; *d d*, rectum; *e*, bladder; *f*, vas deferens; *g*, ureter; *h*, vesicula seminalis; *i*, prostate gland; *j*, urethra; *k k k*, peritonæum, reflected from rectum upon bladder, thence upon the recti muscles.

The direction of the bladder is oblique, being inclined somewhat forwards and upwards. In proportion to the degree of distension the obliquity is increased, in consequence of the neck being fixed. It is retained in its position by two lateral ligaments, one on each side, and an anterior ligament; the lateral ligaments are prolongations of the fascia iliaca, which passing down into the pelvis assumes the name of fascia pelvica, and becomes identified with the prostate gland and side of the bladder. The anterior ligament is double, and it is formed by the fascia transversalis, which passing down behind the symphysis pubis is reflected upon the upper surface of the prostate gland; from the point of reflection two strong fasciculi of fibres pass to the anterior surface of the bladder. These ligaments are sometimes called the proper ligaments of the bladder to distinguish them from certain folds of the peritonæum, sometimes called false ligaments. As the bladder is peculiarly interesting in a surgical point of view, anatomists have endeavoured to describe it precisely, and with this view they have divided it into six regions or surfaces—an anterior, a posterior, two lateral, a superior, and an inferior.

The anterior surface, in the collapsed state of the organ, lies behind the symphysis pubis, with which it is connected by loose cellular tissue; when distended, the bladder rises, and its anterior surface comes in relation, or in contact, with the recti muscles of the abdomen. The posterior surface is covered by the peritonæum, which in the male is reflected upon it from the rectum, in the female from the uterus and vagina; it is then reflected from the sides of the bladder to the iliac fossæ; at the points of reflection it forms folds, one on each side and two posteriorly; these have been improperly described as ligaments, for instead of confining the bladder they serve rather as provisions to facilitate its expansion.

The lateral regions are partially covered by the peritonæum; running along them we find the umbilical arteries, or their remains, in both sexes, and the vasa deferentia in the male. The superior region, or fundus, is partially covered by the peritonæum, which is reflected thence on to the inner surface of the recti muscles; it has a fibrous cord attached to it termed the urachus, which lies between the peritonæum and the recti muscles, and being accompanied by the remains of the umbilical arteries extends to the umbilicus, where it becomes identified with the abdominal aponeuroses. This fibrous cord appears to be useful in retaining the bladder in its situation, for never in the human subject, except in certain cases of malformation, which are very rare, does it present the form of a canal, such as it is found to be in the young of certain quadrupeds, in which it is the medium of communication between the bladder and a bag, or sac termed the allantoid.

The secretion of the urine is performed by the kidneys [Kidney]; it is constantly going on, and does not exhibit those alternations of action and repose observable in the other secretions.

The urine, being secreted, dribbles along the ureters, and its descent is probably aided by the contractility of these tubes and the impulse of the neighbouring arteries. It drops into the bladder and gradually distends it, but it is prevented from regurgitating into the ureters in consequence of these tubes taking an oblique course between the muscular and mucous coats before they perforate the latter. As the urine accumulates, these tubes are more and more compressed, and the obstacle to regurgitation is increased; but the column of urine descending along the ureters, being higher than that contained in the bladder, is not prevented from entering into it.

When a sufficient quantity of urine is accumulated in the bladder, varying according to the degree of irritability of the organ, a general uneasy sensation is produced, and a more particular one referred to the trigone vesicale: the diaphragm and abdominal muscles are called into action, the resistance of the neck of the bladder is overcome (the sphincter, if we admit its existence, relaxes), the muscular fibres of the bladder contract, and are able without further assistance to evacuate every drop of its contents.

BLADDER-CATCHFLY. [Silene.]

BLADDER-GREEN. [Rhamnus.]

BLADDER-NUT. [Staphylea.]

BLADDER-SENNA. [Colutea.]

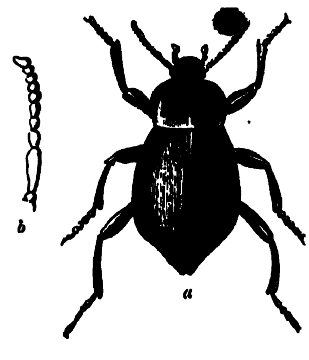
BLADDERWORT. [Utricularia.]

BLAKEA, a genus of plants belonging to the natural order *Melastomaceæ*, named by Dr. Patrick Browne in honour of Martin Blake. The species are trees or shrubs with large showy red flowers. The calyx is girded with from four to six broad scales; the corolla with six petals; the fruit a 6-celled berry, crowned with the calyx. The leaves have from three to five nerves. *B. quinquenervis*, Aublet, *B. triplinervis*, Linnæus, is a native of Brazil, Guyana, and Trinidad. It produces a large yellow berry, which is eaten in the countries where it grows. *B. parasitica* is a native of Guyana and Maranham, having red flowers. It is a climbing shrubby plant, rooting itself in other trees. It yields a colouring matter employed for dyeing red.

BLAPS (Fabricius), a genus of Insects belonging to the order *Coleoptera*, of the section *Heteromera*, and family *Melasoma* (Latreille). The principal generic characters are:—Antennæ with the two basal joints short, their breadth equalling their length; the third joint long, exceeding that of the two following together; the three following joints are longer than broad; the remaining joints nearly round, excepting the terminal one, which is round at the base and acuminated towards its extremity; maxillary palpi with the terminal joint flattened, and when viewed from above or below somewhat hatchet-shaped; thorax broad, sides rounded, posterior margin straight: abdomen oblong-ovate, exceding the thorax in width: elytra generally soldered together, incurved so as to embrace the sides of the abdomen, more or less acuminated towards the apex, and prolonged to a point at the apex.

The species of this genus are tolerably abundant, and frequent dark damp situations, such as the caverns in rocks, &c. In this country there are only two well-authenticated species, *Blaps obtusa* and *B. mortisaga:* the latter is very common in our kitchens and cellars (in company with the cockroach); the former is much less abundant. It is occasionally found with *B. mortisaga.*

Both species are of an obscure black colour, and about three-quarters of an inch in length. As *B. mortisaga* is a well-known common species, we will merely mention the characters, distinguishing the rarer one from it. The first striking difference is the superior breadth in *B. obtusa;* the antennæ are shorter, the fourth, fifth, and sixth joints are scarcely longer than broad (while in *B. mortisaga* their length is nearly double the breadth): the thorax has its hinder angles rounded (in *mortisaga* they are acute): the legs are much shorter in proportion, and the elytra are distinctly punctured.



a, *Blaps obtusa*, rather above the natural size; *b*, an antenna of the same magnified.

Baker relates that he kept a Darkling Beetle (*B. mortisaga*) three years without food.

(Kirby and Spence, *Introduction to Entomology.*)

BLA'TTIDÆ, a family of Insects of the order *Orthoptera.*—Distinguishing characters: tarsi 5-jointed, the under wings folded longitudinally only, head hidden by the thorax; body oval or rounded, and depressed; antennæ long and thread-like, and composed of a great number of very minute joints; palpi long; thorax large, slightly convex, generally broader than long, and as it were a shield, covering the head and base of the wing-cases, which latter are of a parchment-like nature, and ramified with nerves; one elytron laps over the other; the posterior extremity of the abdomen is furnished with two conical articulated appendages; legs furnished with spines.

The *Blattidæ* are extremely active voracious insects, some species apparently eating almost anything that comes in their way. Mr. Stephens enumerates seven species indigenous to this country, and four that are not strictly so; among the last mentioned, the well-known and troublesome Cockroach (*Blatta orientalis*) may be enumerated. It is said to have come originally from Asia, but on this point there is some little doubt; the nocturnal habits and ravages of this species are too well known to need description. The male in its mature state has wings extending only half the length of the body; the female has only rudimentary wings; her eggs, which are about 16 in number, are deposited inclosed in an oblong, nearly cylindrical, but slightly compressed case, with an elevated serrated edge on one side: this at first is of a whitish colour, but after a little time becomes brown and of a firm nature; the female carries this case about with her at first, fixed to the abdomen by a gum-like substance. From this asylum the young make their escape by emitting a fluid which softens a part of the case.

The species of this family have been divided into two genera by Latreille; *Blatta* and *Kakerlac* (a named used for the *Blattæ* by the American colonists), the latter division including those species in which the females are apterous (of which the *B. orientalis* forms a type), and the former those in which both sexes possess wings.

The number of exotic species of this tribe is very great; the indigenous species of this country are—*B. Germanica, pallens, perspicillaris, Panzeri, nigripes, livida, pallida,* and *Lapponica.* Most of these are comparatively small, and are found in woods; the last-mentioned species is said to swarm in the huts of the Laplanders, where it commits great havoc, and in conjunction with *Silpha Lapponica* has been known to devour their whole supply of dried fish in a single day.

(Kirby and Spence, *Introduction to British Entomology;* Stephenson, *Illustrations of British Entomology.*)

BLAUW-BOC, or BLUE BUCK. [ANTILOPEÆ.]

BLAZING-STAR. [HELONIAS.]

BLECHNUM, a genus of plants belonging to the natural order of Ferns and the tribe *Adiantariæ.* It has its thecæ in a continuous line parallel to the midrib upon the transverse anastomosing veins, and covered by a continuous scarious indusium. There is but one British species of this genus, the *B. boreale,* Hard Fern. It has barren pectinate-pinnatifid fronds, with broadly linear rather obtuse pinnæ, fertile frond pinnate, pinnæ linear acute. This plant is exceedingly common in Great Britain, and is found almost everywhere in woods, on commons, heaths, and all uncultivated ground. It occurs in every European list of plants, and has been found in Northern Africa and North America. It is the *Lomaria Spicant* of Desveux, who is followed by Mr. Newman, in his 'History of British Ferns.' Linnæus described it as an *Osmunda.* The roots of this fern are black, tough, and wiry; the rhizoma tufted and hairy. The other species of *Blechnum* are inhabitants of South America, Australia, and the Cape of Good Hope. They are frequently cultivated in collections of Ferns. (Babington, *Manual;* Newman, *History of British Ferns.*)

BLE'DIUS, a genus of Insects of the order *Coleoptera* and family *Stenidæ.* Antennæ with the basal joint very long, the remaining joints bent at an angle with the first; maxillary palpi with the second and third joints large, terminal one slender; mandibles armed with a tooth internally towards the apex; body elongate and cylindrical; head furnished with two tubercles or spines; thorax armed with a horn in the males; legs short, the four anterior tibiæ broad and flat, having numerous spines on the external part; tarsi four-jointed.

The *Bledii* appear to be peculiar to the sea-coast, where they burrow in the wet clay or sand near pools of water, by means of the spined anterior tibiæ above described. They are gregarious in their habits. Three species have been discovered in this country, all of which are of a black colour, with the wing-cases more or less red.

Bledius tricornis, in the male sex, has two short horns on the head, and one long smooth horn proceeding horizontally from the front of the thorax. Length about 3-12ths of an inch.

B. Taurus, in the male, has two long and slender horns on the head; the thoracic horn is pubescent at the apex; about the same size as the last.

B. Ruddii has short acute horns on the head, and the thoracic horn pubescent at the apex; it is rather less than the two foregoing species.

BLE'MUS, a genus of Insects of the order *Coleoptera* and family *Harpalidæ.* Head almost as large as the thorax, the portion joining the anterior part of the eyes distinctly elevated; antennæ very long; palpi with the terminal joint somewhat conical and rather acute; labium slightly notched in front; thorax considerably narrowed posteriorly; body elongate and rather depressed; wings ample; the joints of the anterior tarsi of the male dilated.

About six British species of this genus have been discovered, the largest of which does not exceed 3-12ths of an inch. All the species are of a pale-yellow or ochre colour, having more or less of a bluish shade on the disc of the elytra, excepting *B. consputus,* which although generally placed in this genus we do not consider as strictly belonging to it. *B. fasciatus,* which may be considered the type of the genus, is rather more than 2-12ths of an inch in length, and of a pale ochre-colour, with a blue-black fascia crossing the elytra. This beautiful little species has been found near London, and in various other parts; but, like all the species of this genus, is rather scarce.

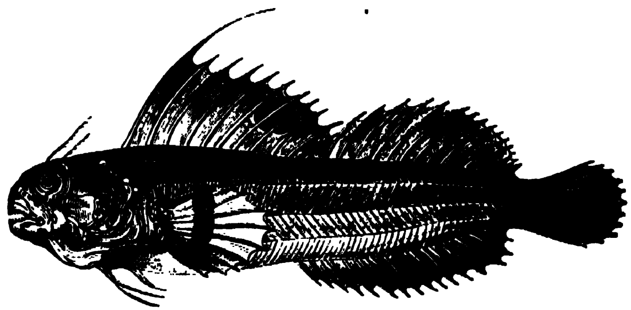
BLENDE, a name particularly given to Zinc-Blende, but most commonly used by mineralogists as denoting an order which in the system of Professor Jameson of Edinburgh contains the following genera:—Manganese-Blende, Zinc-Blende or Garnet-Blende, Antimony-Blende, Ruby-Blende. The word is probably derived from a German verb (used only in combinations) signifying to mix: the term 'blende' signifies a mineral which contains no ore—in fact a pseudo-galena. [ZINC.]

BLE'NNIUS, Blennies (French, Baveuses), a genus of Fishes of the section *Acanthopterygii* and family *Gobioidæ* (Gobies). Both the Greek and the French names have been applied to this genus from the mucous matter with which the bodies of these fishes are covered. They may be easily distinguished by their having the ventral fin placed before the pectoral, and containing generally but two rays. The head is short and rounded; teeth long and slender, and placed in a single row; body long, compressed, smooth, and possessing only one dorsal fin, which extends nearly the whole length of the back; they have no air-bladder.

The species of this genus are small, live in shoals, but not in great numbers. They are very active and tenacious of life, and frequent rocky coasts, where they may often be found in the pools of water left by the tide, hiding themselves among the weeds and in the crevices of the rocks.

The genus *Blennius* of Linnæus, in Cuvier's 'Règne Animal,' is divided into the following subgenera: *Myxodes Salarias, Clinus, Cirrhibarba, Murænoides, Opistognathus,* and *Zoarcus.* At present we confine ourselves to the Blennies, properly so called, of which, according to Mr. Yarrell, we have five species frequenting our coasts. The first, *B. Montagui,* Montagu's, or Diminutive, Blenny, is generally of an olive-green above, spotted with pale-blue shaded to white; belly white, pectoral fins spotted with orange. The head, viewed laterally, forms an obtuse angle in front, and is furnished with a transverse conic or angular fimbriated crest. The dorsal fin has 30 rays, pectoral 12, ventral 2, anal (which extends from the vent to the tail) 18, and the caudal (which is rounded) 14. It is found on the south coast of Devon.

B. ocellaris, the Ocellated Blenny, or Butterfly-Fish, is scarcely three inches long, the head is rounded, the part anterior to the eyes very short, and above the eyes two slender fimbriated appendages are situated; body elongate; dorsal fin extending from the back part of the head to the tail, and consists of 26 rays, of which the first is considerably longer than the rest, the nine following diminish in length to the eleventh, which is shortest, the twelfth nearly double the length of the last, from this the remaining rays gradually increase in length to about half-way, and then decrease towards the tail; a large dark-brown spot extends from the sixth to the ninth ray. The pectoral fins have each 12 rays, ventral 2, anal 17, and caudal 11. The body is of a pale-brown colour, varied with patches of a deeper hue; the pectoral and ventral fins are darker than the others. This species frequents the coast of Devonshire and elsewhere, but is not common.



Butterfly-Fish (*Blennius ocellaris*).

B. gattorugine, the Gattoruginous Blenny, is about five or six inches in length; it is elongate, rather robust anteriorly, the forehead slopes considerably from the posterior part to the anterior; the head is grooved between the eyes, and furnished with two branched membranes situated just above the eyelids; the dorsal fin extends from the back part of the head to the tail, the central part is very slightly narrower than the rest. The fins and body are of a dark reddish-brown colour, the belly and hinder portion of the former is of a paler brown. The dorsal fin has 33 rays, the pectoral fins are broad and rounded, and have each 14, the ventral fin 2, and the anal 23 rays; the tail is slightly rounded, and has 11 rays. It has been found in Poole Harbour and other parts. Not common.

B. pholis, the Shanny. In this species all the rays of the dorsal fin are nearly of equal length, except the eleventh and twelfth (which are short); the number of these rays is 31, pectoral 13, ventral 2, anal 19, caudal 11; the colour is very variable, but consists of shades of brown.

B. pholis may however be readily distinguished from any of the known British species by the absence of the appendages on the head.

B. Yarrellii, the Crested or Yarrell's Blenny. This species may be known by its elongated even shape, the uniform length of the rays of the dorsal fin, the form of the tail (which has the external rays shortest, the others increasing in length to the middle, thus being somewhat lanceolate in shape), and the four appendages of the head which are all fimbriated. Two of these appendages are placed one over each eye, and connected by a transverse fold of skin; behind these are placed the other pair, which are of a larger size. The fin rays are, dorsal 51, pectoral 14, ventral 3, anal 36, and caudal 16.

This species was formerly confounded with *B. palmiconius* and *B. galerita*, but Valenciennes has pointed out its distinctive characters and named it after the distinguished British icthyologist whose name it now bears. A specimen of this very rare British fish was exhibited amongst the earliest specimens in the Aquavivarium in the Regent's Park, and is still alive (July, 1853). Many other species of Blenny have been exhibited in the tanks of the establishment. All the species are remarkable for the facility with which they use the ventral fins for enabling them to cling to and move about upon the rocks and stones by which they are surrounded.

BLE'PHARIS, a genus of Acanthopterygious Fishes, which according to Cuvier belongs to the seventh family of that tribe, called *Scomberoides*. They may be distinguished by their having long filaments to their second dorsal, and to their anal fin rays; ventrals much prolonged, the spines of the first hardly piercing the skin; body elevated, the profile with the ordinary degree of curvature.

BLE'PSIAS, a genus of Acanthopterygious Fishes, belonging to the section having hard cheeks. Of this genus but one species, *Billosus*, is known, which belongs to the Aleutian Islands. Generic characters: head compressed, cheeks mailed, fleshy barbels under the lower jaw, gills with five rays; one dorsal fin divided into three unequal lobes; ventral fin very small.

BLESS-BOC. [ANTILOPEÆ.]

BLETHI'SA (Bonelli), a genus of Insects belonging to the order *Coleopteræ*, by some authors associated with the family *Harpalidæ*, and by others with the *Elaphridæ*. The former is probably more correct, as doubts may be entertained that the latter family is a natural one. Head large, eyes slightly prominent, mandibles obscurely toothed; palpi with the two terminal joints of equal length, the terminal rather ovate, truncated at the apex; mentum emarginate anteriorly, the emargination with an obscure bifid lobe; antennæ short, the three basal and base of the fourth joints naked; thorax rather short, rounded at the sides; elytra elongated, very convex and impressed with numerous small excavations; anterior tarsi of the male with four slightly-dilated joints.

Of this beautiful genus but one species has been found in this country, *Blethisa multipunctata;* and apparently only two others are yet known on the continent. The species just named frequents marshy situations, and is often found crawling upon willow-trees; it is about half an inch long, and of a rich bronze or brassy hue, by which characters, combined with the numerous indented points on the elytra, it may easily be distinguished.

BLETIA, a genus of plants belonging to the natural order *Orchidaceæ*. The corms of *Bletia verecunda* are said by Dr. P. Browne to have a bitterish flavour, and when dry to be used with advantage as a stomachic.

BLETTING. All ripe fruits after they have been kept for some time begin to decompose, and the spots formed on the fruit during this process have been called by Professor Lindley 'Blets.' During the whole time of the growth of the fruits of plants various important chemical changes go on in their tissues, especially whilst ripening. These changes have been examined with great care by Berard. At first the flesh of most fruits consists of fibrous or cellular tissue, which is mostly composed of lignine. The liquid of fruits is sap, which exists between the cells in the intercellular passages. This liquid, besides a great quantity of water, contains sugar, gum, malic acid, malate of lime, colouring matter, a peculiar vegeto-animal substance (protein), and an aromatic secretion proper to each fruit. In such fruits as the grape there is tartrate of potash and lime; in the lemon and the gooseberry, citric acid. As the process of ripening goes on, the quantity of water diminishes, and the sugar increases. This sugar is formed at the expense of the lignine, and is either in a concrete state, as in the grape, fig, and peach, or fluid, as in most fruits. It is after this period that Bletting comes on, and changes take place in the fruit which render it unfit for the ordinary uses of man. Bletting is attended with the formation of carbonic acid, the nitrogenised substance enters into a state of putrefaction, and the sugar undergoes fermentation. These processes are undergone most rapidly when the fruit is exposed to the action of the oxygen of the atmosphere. The fruits in which these changes have been most accurately observed are the pear and the apple. A jargonelle pear was found to have sustained a loss of its constituents in the following proportion:—

	Ripe.	Bletted.
Lignine . . .	2·19 . . .	1·85
Sugar . . .	11·52 . . .	8·77
Water . . .	83·88 . . .	62·73

It acquired rather more malic acid, gum, and nitrogenised matter.

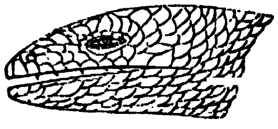
The fact has been observed by Dr. Hassall that in all bletted fruits there exists a low form of *Fungus*, which he considers the cause of the decay. He found, on inoculating sound fruits, even while growing on the tree, that he could produce immediately the process of decay, and wherever this was indicated by bletting, there he discovered the fibres of the fungus with the microscope. This appearance of the fungus however is only in accordance with what we know of the habits of fungi, whose sporules, being everywhere diffused through the air, immediately spring up where a fitting nidus is found for their growth. We find that as soon as a fruit becomes ripe its constituents commence union with the oxygen of the air, forming carbonic acid gas, and it is during this state of their elements that the fungus finds a soil ready for its development.

Whichever view be taken of the rotting of fruits, their preservation must be conducted on the same principle, for what will exclude oxygen will exclude the sporules of fungi. As a simple process it has been recommended to place at the bottom of a bottle a paste formed of lime, sulphate of iron, and water, and then to introduce the fruit, which has been pulled a few days before ripening. The fruits should be kept from the bottom of the bottle and as much as possible from each other, and the bottle should be closed by a cork and cement. In this way peaches, prunes, and apricots may be kept from 20 days to a month; pears and apples for three months. Dr. Hassall recommends that fruits should be washed over with a composition consisting of water one pound, shell-lac and borax two ounces.

(Lindley, *Introduction to Botany;* Hassall, *Transactions of Microscopical Society*, vol. i.)

BLI'GHIA, a genus of plants named after Captain William Bligh, R.N., master of the Bounty in the celebrated mutiny, belongs to the natural order *Sapindaceæ*. It has a 5-parted calyx, 5 petals, a very short style, 3 stigmas, and a solitary seed with a very large arillus. Only one species of this genus has been described, the *B. sapida*, Akee-Tree. It is a native of Guinea, from whence it has been introduced into the West Indies and South America. It is a tree attaining a height of 30 or 40 feet. It has pubescent leaves, with three or four pairs of ovate-lanceolate veined leaflets. The fruit of this tree is a berry of a reddish or yellowish colour, about the size of a hen's egg. The aril of the seed is pulpy, and of a grateful subacid flavour, and is eaten in Africa and the West Indies. This tree does not produce flowers in this country. It may however be easily cultivated. It grows well in a mixture of loam and peat. Cuttings will strike in sand under a hand-glass. They should not be deprived of any of their leaves. (Loudon, *Encyclopædia of Plants.*)

BLIND-WORM, the English name for a species of Reptile belonging to the family of *Anguidæ*, Les Orvets of the French, and the genus *Anguis* of Linnæus. It is also called in England Slow-Worm. The Blind-Worm (*Anguis fragilis*), is common throughout Europe. Its length varies from about 11 inches to somewhat more than a foot, and instances have been given of its attaining more than double that length. The eyes are small (whence one of its names), and the irides are red. The head is small, the teeth are minute and numerous, the neck is slender, and thence the body enlarges, continuing of equal bulk to the tip of the tail, which ends bluntly, and is as long as the trunk, or body part. The scales are very smooth, shining, of a silvered yellow on the upper parts, and dusky beneath; the sides are of a somewhat reddish cast. Down the back extend three black lines, which change with age into different series of black specks, and at length disappear. The general colour of the back may be described as cinereous, with somewhat of a metallic lustre, and marked with very fine lines of minute black specks. The dusky belly and the reddish sides are marked like the back.



Head of Blind-Worm

The Blind-Worm feeds on earth-worms, insects, &c.; and the slowness of its motion has obtained for it another of its names. Though perfectly innocuous, it has the character of possessing the most deadly venom, and is persecuted accordingly. Pennant quotes Dr. Borlase as assisting this idle and groundless notion, by mentioning a variety of this serpent with a pointed tail, and adding that he had been informed that a man lost his life by the bite of one in Oxfordshire. Now, if the serpent that bit the man in Oxfordshire had a pointed tail, it could not have been a blind-worm; and if the story of the death be true, he most probably lost his life by the bite of a black or dusky viper, as Pennant suggests. [VIPER.] The country people still hold this harmless reptile in utter abhorrence, and wage an exterminating war against it: but the reader may be assured that the 'blind-worm's sting' exists only in imagination. The animal is very brittle. Laurenti and others assert that when captured it throws itself into such rigidity that it sometimes breaks in two. A smart blow with a switch divides it; and from this fragility Linnæus gave it the specific name which it still retains. Cuvier is of opinion that the *Anguis eryx* of Linnæus is only a young blind-worm, which has the dorsal lines well marked, and that the *Anguis clivicus*, which Daudin makes an *Eryx*, is nothing more than an old blind-worm with a truncated tail. The Blind-Worm, or Slow-Worm, of the old English authors is the Long Cripple of the Cornish, according to Borlase ,Ormala and Koppar-Orm of the 'Fauna

Suecica,' L'Orvet of Lacépède, Blind Schleiche of the Germans, *Anguis fragilis* of Linnæus. It brings forth its young alive, and it is said twice a year, in the seasons of spring and autumn.

The general opinion is (and we think it well founded) that the Blind-Worm is the *Cæcilia* of the Latins, and the Τύφλωψ and Τυφλῖνος of the ancient Greeks, names given in allusion to its supposed blindness, and that it was sometimes called Κωφίας on account of its assumed deafness. Belon considers it to be the serpent called Tephloti, Tephliti, and Tephlini by the modern Greeks. Columella ('De Re Rusticâ,' 6. c. 17), following the opinion of its deleterious nature, says that its poison is fatal to oxen, and that the cure is the flesh of storks, because they devour this serpent. Upon the principle, we suppose, of counteracting one poison by the application of another, a Theriaca, or poison-antidote, made from the harmless Blind-Worms (*Cæciliis*) and the theriacal water was used as a sudorific against the pestilence. Mr. Bell says this creature is kept alive with difficulty in confinement. It feeds on worms, insects, slugs, &c. Its habits are exceedingly gentle and inoffensive, and even should it attempt to bite when irritated it is incapable of producing injury. (Bell, *British Reptiles*.)

BLINDS, a name given in Devonshire and Cornwall to the Whiting Pout. [MORRHUA.]

BLITUM (from βλίτον), a genus of plants belonging to the natural order *Chenopodiaceæ*. It has no corolla, a trifid calyx, a pistil with 2 styles, a single seed immersed in its berried calyx. Two species of this genus are known by the name of Strawberry Blite—*B. capitatum* and *B. virgatum*. The former has its flowers in terminal spikes; the latter has its heads lateral and scattered. Some writers have made the *B. virgatum* only a variety of the first, but its axillary flowers are constant. After flowering, the calyx of these two species swells out, and presents the size, colour, and appearance of the common wood-strawberry. It is succulent, stains the hands, and was formerly used for colouring puddings. The taste is insipid. These plants are not natives of Great Britain, but are common on way-sides and in cultivated grounds in the south of Europe. The species of *Chenopodium* are closely allied to those of *Blitum*; and Meyer, Reichenbach, and Koch have referred the European species of *Chenopodium* with vertical seeds to the genus *Blitum*. These are the *C. rubrum*, *C. Bonus Henricus*, and *C. glaucum* of Babington's 'Manual of British Botany,'—all three of which are Linnæan species.

(Koch, *Flora Germanica*; Loudon, *Encyclopædia of Plants*; Babington, *Manual*.)

BLOOD, the animal fluid by which the tissues of the body are nourished, and which is contained in the tubes called from their office Blood-Vessels.

On first flowing from the vessel in which it is contained the blood is a thick, viscid, and tenacious fluid. In all the more highly-organised animals it is of a red colour: but redness is not one of its essential properties. In several tribes of animals which possess true and proper blood, this fluid is not of a red colour, and there is no animal whose blood is visibly red in all the parts of the body. The blood of the insect is colourless and transparent; that of the reptile is of a yellowish colour; in the main part of the body of the fish, that is, in the whole of its muscular system, the blood is without colour; hence the whiteness of the general substance of the body of the fish: but in the more important organs, and especially in those which constitute the circle of nutrition, called the organs of organic life, the blood is of a red colour, as in the heart, the branchiæ or gills, and so on. In the bird the blood is of a deep red; but it is the deepest of all in the mammalia. In some species of mammalia it is deeper than in others; in the hare, for example, it is much deeper than in the rabbit. It is deeper in some varieties of the same species than in others, and more especially in different varieties of the human family.

In man and all the higher animals the body contains two kinds of blood, each of which is distinguished by a striking difference of colour. Each kind of blood is contained in its own peculiar set of vessels: the one in the vessel called a vein, hence called venous blood; the other in the vessel called an artery, arterial blood. Venous blood is of a dark or Modena-red colour; arterial blood is of a bright scarlet colour. Venous differs from arterial blood in its most essential properties no less than in its colour: venous blood is incapable of nourishing the body and of stimulating the organs; arterial blood is the proper nutrient and stimulant of the system.

The specific gravity of human blood (water being 1000) may be stated to be about 1055 or 1056, from which standard it is capable of increasing to 1120, and of sinking to 1026, this being the extreme range of variation hitherto observed. Venous is heavier than arterial blood, the former being commonly estimated at 1052, and the latter at 1049. The higher the organisation of the blood the greater is its specific gravity: hence the specific gravity of the blood of the higher is greater than that of the lower animals.

There is a remarkable difference in different classes of animals in the temperature of the blood. In some it is only a degree or two above that of the surrounding medium. Creatures with blood of this low temperature are called cold-blooded, in contradistinction to warm-blooded animals, whose temperature is maintained under whatever variety of circumstances they may be placed considerably above that of the surrounding air.

The following table of the temperature of the blood of different animals, is compiled from the researches of Tiedemann and Rudolphi on this subject.

Animal.	Degrees of Fahrenheit.
Great Titmouse	111·25
Swallow	111·25
Ducks and Geese	106 to 111
Common Hen	102 to 109
Species of Eagles, Hawks, &c.	104 to 109
Pigeon	106 to 109
Gull	100
Bat	106
Squirrel	105
Ox	104
Ape	103
Dog	101
Cat	98 to 103
Elephant	99
Horse	98·24
Man	98

Arterial is warmer by one degree than venous blood.

Disease is capable of effecting a considerable change in the temperature of the blood. In almost every case of fever the temperature of the blood differs from the natural standard. In the cold fit of intermittent fever (ague) it sometimes sinks as low as 94°; in some types of continued fever it rises as high as 102°. In cholera it sinks to 90°. In inflammation of moderate severity it exceeds the natural standard by 4 degrees; in intense inflammation it is capable of rising above it as high as 7 degrees.

The blood, whilst circulating in the body is composed of two parts, a liquid and a solid. The liquid is called liquor sanguinis, and the solid, on account of its cellular character, blood-globules or corpuscles. When blood is allowed to stand, after it is taken from the body, it separates into two distinct parts, a solid mass, and a fluid matter in which the solid mass swims. The solid portion of the blood, which includes the blood-corpuscles and a portion of the liquor sanguinis called the fibrin, is termed the Clot, or the Crassamentum; the fluid portion is called the Serum; and the process by which the separation takes place is denominated Coagulation.

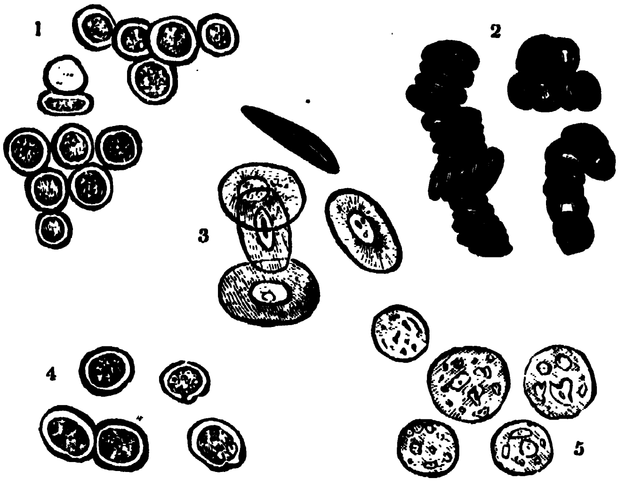
The change in the constitution of the blood by which this separation into a solid and fluid portion is effected commences directly the blood leaves the blood-vessel. In about eight or nine minutes after blood is drawn from a living animal it begins to thicken, and in the course of a quarter of an hour the clot begins to form, and the serum exudes. This process arises from the fact that the fibrin is not dissolved, only suspended in the blood, and when allowed to stand it separates, sinking in the liquid blood, and carrying with it the blood-corpuscles. When the latter separate from the fibrin, which they do under various circumstances, forming a layer at the lower part of the clot, the upper part of the clot, which is of a yellow or buff colour, is called the buffy coat.

The Coagulation of the Blood is not simply a separation of the fibrin from the serum of the blood, dependent on physical causes, as is evident from the manner in which it is hastened or delayed by external causes. This may be stated without the necessity of making any inferences from the phenomena presented. Temperature exerts an influence, as cold delays coagulation, whilst moderate heat hastens its occurrence. Exposure to the atmosphere facilitates this process, as also contact with foreign bodies; but the exclusion of air delays it. The cessation of active motion whilst the blood is in the body hastens coagulation, but movement also gives a tendency to it out of the body. A mixture of half the bulk of the blood with water increases the coagulative tendency, but increased dilution diminishes it. States of the system affect it. Faintness is favourable to coagulation, but excitement and suffocation retard it. Coagulation is quicker in arterial than in venous blood. Foreign substances generally hasten it, but alkalies delay it.

The Clot or Crassamentum separates into two portions—a substance of a yellowish-white colour forming the top of the clot, and a red mass always found at the bottom of the clot. When the yellowish substance forming the top of the clot is completely separated from the red mass it is found to be a solid of considerable consistence, soft, firm, elastic, and tenacious, or gluey. Its distinctive character is derived from the disposition manifested by its component particles to arrange themselves into minute threads or fibres; these threads or fibres are often so disposed as to form a complete net-work. In its general aspect as well as in its chemical relations this substance bears a striking resemblance to pure muscular fibre; that is, to muscular fibre deprived of its enveloping membrane and of its colouring matter. Several names have been given to this substance—gluten, coagulable lymph, fibre of the blood, and fibrin; the latter is the name commonly appropriated to it. Of all the constituents of the blood Fibrin is by far the most important. Whatever other constituent may be absent, this in all animals which possess blood is invariably present. The main part of all the solid structures of the body is composed of it; it forms the basis of muscle, and in the lower animals, in which distinct muscular fibres cannot be traced, it probably performs the function of muscle. This substance or some modification of it is also found in plants, and seems to be the chemical compound with which the active functions of life are connected.

The second constituent of the Clot, the red matter, being heavier than the fibrin, gradually subsides to the lower surface, where it is always found forming the bottom of the clot. The proportion of this red matter to the fibrin differs in different classes of animals, and even in the same animal at different times. The greater the energy and activity of the animal the larger is the proportion of the red matter, and it is also generally large in proportion to the elevation of the animal temperature.

When a drop of blood is placed under the microscope it is found to consist of the liquor sanguinis and a number of globules or cells. It is these latter which constitute the red matter of the blood. When carefully examined these cells are found to be of two kinds—the one white or colourless, the other red. The former except in states of disease are far less in number than the latter, and are found to be identical with cells which are found in the lymph and chyle. Hence they are sometimes called lymph- or chyle-corpuscles. These white corpuscles have only of late years attracted much attention, though they had been described as far back as the time of Hewson. In man and the mammalia they are often larger than the red corpuscles; they may be recognised by their granular appearance, their peculiar contour, and the irregular shading of their figure. (*Figs.* 4 and 5.)



Blood-Corpuscles.

1, Red corpuscles of human blood, exhibiting their flattened surfaces; 2, the same, adherent by their flattened surfaces so as to form rolls; 3, red corpuscles of frog's blood; 4, colourless corpuscles of human blood; 5, the same, enlarged by the imbibition of water.

They are also to be distinguished from the red corpuscles by their different actions towards chemical re-agents; they are not attacked by water, but remain in it for a long time without apparent change; they are not rendered transparent and dissolved by acetic acid; they only become more decidedly granular under its action, and a kind of nucleus is developed in their centre. As they are in all respects similar to those of lymph and chyle, and as they have the same chemical relations, they have been regarded by many as the corpuscles of the lymph mingled with the blood (Hewson, Müller); others have viewed them as globules of coagulated fibrin (Mandl, Weber); and others again with more propriety as blood-corpuscles in progress of solution or disintegration (Wharton Jones, Hughes Bennett). They may be seen in the capillary system of living animals (in transparent structures, as for instance in the frog's foot) swimming with the ordinary blood corpuscles, but not so much moving rapidly in the great current of the blood as progressing in close contact with the walls of the vessels in a slower stream. They are not elastic like the ordinary corpuscles, and seem to stick to each other. The exact functions of these corpuscles are still unknown, but there are many facts which seem to indicate that there is a decided relation between them and between the nutritive or organic life of the tissues.

In addition to these cells, which as we have said are comparatively rare, an immense number of what are termed 'red corpuscles,' but which usually present a yellow appearance, are present in the red matter. The blood of numerous animals has been submitted to microscopic examination by Nasse, Wagner, Gulliver, and other observers, and in general it is found that these red particles have a circular form in all animals constituting the class Mammalia. A remarkable exception to this rule has been shown by Mandl to occur in the corpuscles of the camel tribe. The mean long diameter of the blood-corpuscles of the Dromedary he found to be the 3254th of an inch, while the mean short diameter was only the 5921st of the same standard. In the Paco (*Auchenia paco*) and Guanaco (*Auchenia glama*) the blood-corpuscles scarcely differed in form and size from those of the dromedary, whilst in the Vicuña they were slightly smaller. In structure and magnitude however these oval corpuscles of the *Camelidæ* belong entirely to the mammiferous type; they have no perceptible nucleus like those of birds, and they are not much more than half the size of even the smallest that have been observed in birds or reptiles.

The difference of size in the corpuscles of different mammalia is worthy of notice. The average diameter of those of man, according to Mr. Gulliver, is the 3300th of an inch; but the average diameter of those of the elephant, according to the same observer, is as much as the 2745th of an inch (which were the largest he observed amongst the mammalia), whilst those of the Napu musk-deer were no more than the 12,325th, and some were as small as the 16,000th of an inch in diameter. There is also an exception to the general statement that the corpuscles of fishes are oval; in one class, namely the *Cyclostomi*, or Lamprey Tribe, they are circular. The largest red corpuscles hitherto observed are amongst the reptiles known as the Syren and the Proteus, which are so large as even to be visible to the naked eye as very minute specks.

There can be no doubt that the red corpuscles go through the same course as other cells. We have undoubted evidence of their rapid regeneration in cases where much blood has been lost, and of the peculiar power which chalybeate medicines have in forwarding their production. The precise method in which they are developed is however not exactly known.

With respect to the chemical composition of the blood-corpuscles, the walls are formed of a substance which has been called globulin, and which is undoubtedly a protein compound. The red colour is due to a pigment which has received the name of Hæmatin, and is inclosed in the vesicles of globulin. It has been generally assumed that this substance exists in two distinct states in arterial and venous blood, having in the former an excess of oxygen and in the latter an excess of carbon or carbonic acid. Mulder has however shown that its elementary composition is the same whether obtained from arterial or venous blood, and that it may be represented by the formula $C_{44}H_{22}N_3O_6Fe$; the following being the analyses from which he deduced it :—

	1	2	3	4	5	According to the formula.
Carbon .	66·49	65·91	66·20	65·73	65·90	65·84
Hydrogen	5·30	5·27	5·44	5·28	5·27	5·37
Nitrogen	10·54	..	10·46	10·57	10·61	10·40
Oxygen .	11·01	..	11·15	11·97	..	11·75
Iron .	6·66	6·58	6·75	6·45	..	6·64

1, 2, and 3 were arterial, and 4 venous ox-blood; 5 was the mixed blood of a sheep.

It may be shown by conclusive experiments that the red colour is not dependent on the iron, for that constituent may be removed from the hæmatin without materially altering its tint, although it is very firmly combined with the four organic elements. The condition in which the iron exists in hæmatin—whether as an oxide, a carbonate, a carburet, or in the metallic state—has long been disputed. According to Liebig the iron of the hæmatin is the most essential constituent of the blood in relation to the respiratory process. The following is his view of the theory of respiration :— "During the passage of the venous blood through the lungs, the globules change colour, and oxygen is absorbed from the atmosphere. Further, for every volume of oxygen absorbed, an equal volume of carbonic acid is in most cases given out. The red globules contain a compound of iron, and no other constituent of the body contains iron. Whatever changes the other constituents of the blood undergo in the lungs, this much is certain, that the globules of venous blood experience a change of colour, and that this change depends on the action of oxygen. Now we observe that the globules of arterial blood retain their colour in the larger vessels, and lose it only during their passage through the capillaries. All those constituents of venous blood which are capable of combining with oxygen take up a corresponding quantity of it in the lungs. Experiments made with arterial serum have shown that when in contact with oxygen it does not diminish the volume of that gas. Venous blood in contact with oxygen is reddened, while oxygen is absorbed, and a corresponding quantity of carbonic acid is formed. It is evident that the change of colour in the venous globules depends on the combination of some one of these elements with oxygen; and that this absorption of oxygen is attended with the separation of a certain quantity of carbonic acid gas. This carbonic acid is not separated from the serum; for the serum does not possess the property when in contact with oxygen of giving off carbonic acid. On the contrary, when separated from the globules it absorbs from half its volume to an equal volume of carbonic acid, and at ordinary temperatures is not saturated with that gas. Arterial blood, when drawn from the body, is soon altered; its florid colour becomes dark red. The florid blood, which owes its colour to the globules, becomes dark by the action of carbonic acid, and this change of colour affects the globules, for florid blood absorbs a number of gases which do not dissolve in the fluid part of the blood when separated from the globules. It is evident therefore that the globules have the power of combining with gases. The globules of the blood change their colour in different gases; and this change may be owing either to a combination or to a decomposition. Sulphuretted hydrogen turns them blackish-green, and finally black; and the original red colour cannot in this case be restored by contact with oxygen. Here a decomposition has obviously taken place. The globules darkened by carbonic acid become again florid in oxygen, with disengagement of carbonic acid. The same thing takes place in nitrous oxide. It is clear that they have here undergone no decomposition, and consequently they possess the power of combining with gases, while the compound they form with carbonic acid is destroyed by oxygen. When left to themselves out of the body, the compound formed with oxygen again becomes dark, but does not recover its florid colour a second time by the action of oxygen. The globules of the blood contain a compound of iron. From the never-failing presence of iron in red blood, we must conclude that it is unquestionably necessary to animal life; and since physiology has proved that the globules take no share in the process of nutrition, it cannot be doubted that they play a part in the process of respiration. The compound of iron in the globules has the characters of an oxidised compound, for it is decomposed by sulphuretted hydrogen, exactly in the same way as the oxides or other analogous compounds of iron. By means of diluted mineral acids, peroxide (sesqui-oxide) of iron may be extracted at the ordinary temperature from the fresh or dried red colouring matter of the blood. The characters of the compounds of iron may perhaps assist us to explain the share which that metal takes in the respiratory process. No other metal can be compared with iron for the remarkable properties of its compounds. The compounds of protoxide of iron possess the property of depriving other oxidised compounds of oxygen; while the compounds of peroxide of iron under other circumstances give us oxygen with the utmost facility. Hydrated peroxide of iron, in contact with organic matters destitute of sulphur, is converted into carbonate of the protoxide. Carbonate of protoxide of iron, in contact with water and oxygen, is decomposed; all the carbonic acid is given off, and by absorption of oxygen it passes into the hydrated peroxide, which may again be converted into a compound of the protoxide. Not only the oxides of iron but also the cyanides of that metal exhibit similar properties. Prussian blue contains iron in combination with all the organic elements of the body; hydrogen and oxygen (water), carbon and nitrogen (cyanogen). When it is exposed to light, cyanogen is given off, and it becomes white; in the dark it attracts oxygen, and recovers its blue colour. All these observations taken together lead to the opinion that the globules of arterial blood contain a compound of iron saturated with oxygen, which in the living blood loses its oxygen during its passage through the capillaries. The same thing occurs when it is separated from the body and begins to undergo decomposition. The compound, rich in oxygen, passes therefore, by the loss of oxygen, into one far less charged with that element. One of the products of oxidation formed in this process is carbonic acid. The compound of iron in the venous blood possesses the property of combining with carbonic acid; and it is obvious that the globules of the arterial blood, after losing a part of their oxygen, will, if they meet with carbonic acid, combine with that substance. When they reach the lungs they will again take up the oxygen they have lost; for every volume of oxygen absorbed, a corresponding volume of carbonic acid will be separated; they will return to their former state, that is, they will again acquire the power of giving off oxygen. For every volume of oxygen which the globules can give off, there will be formed (as carbonic acid contains its own volume of oxygen without condensation) neither more nor less than an equal volume of carbonic acid. For every volume of oxygen which the globules are capable of absorbing, no more carbonic acid can possibly be separated than that volume of oxygen can produce. When carbonate of protoxide of iron by the absorption of oxygen passes into the hydrated peroxide, there are given off, for every volume of oxygen necessary to the change from protoxide to peroxide of iron, four volumes of carbonic acid gas. But from the one volume of oxygen only one volume of carbonic acid gas can be produced. And the absorption of one volume of oxygen can only cause directly the separation of an equal volume of carbonic acid; consequently the substance or compound which has lost its oxygen during the passage of arterial into venous blood, must have been capable of absorbing or combining with carbonic acid; and we find, in point of fact, that the living blood is never in any state saturated with carbonic acid; that it is capable of taking up an additional quantity without any apparent disturbance of the functions of the globules. Thus, for instance, after drinking effervescing wines, beer, or mineral waters, more carbonic acid must necessarily be expired than at other times. In all cases where the oxygen of the arterial globules has been partly expended otherwise than in the formation of carbonic acid, the amount of this latter gas expired will correspond exactly with that which has been formed; less however will be given out after the use of fat and of still wines than after champagne. According to the views now developed, the globules of arterial blood in their passage through the capillaries yield oxygen to certain constituents of the body. A small portion of this oxygen serves to produce the change of matter, and determines the separation of living parts, and their conversion into lifeless compounds, as well as the formation of the scretions and excretions. The greater part, however, of the oxygen is employed in converting into oxidised compounds the newly-formed substances which no longer form part of the living tissues. In their return towards the heart, the globules which have lost their oxygen combine with carbonic acid, producing venous blood; and when they reach the lungs an exchange takes place between this carbonic acid and the oxygen of the atmosphere. The organic compound of iron, which exists in venous blood, recovers in the lungs the oxygen it has lost, and in consequence of this absorption of oxygen the carbonic acid in combination with it is separated."

Mulder is strongly opposed to this theory; he denies that the iron takes any essential part in the respiratory process; and he refers the process entirely to the oxidation of the protein-compounds. He alleges the following grounds against the probability of the correctness of Liebig's views:—

1. The iron is so intimately connected with the other elements of hæmatin, that it cannot be removed even by long digestion of this constituent in dilute hydrochloric or sulphuric acid. If these re-agents cannot effect its oxidation, it is highly improbable that it should be oxidised in the lungs. Respecting Liebig's assertion that dilute acids remove iron from dried blood, Mulder proves that this fact is valueless in relation to his theory, because other constituents of the blood besides the hæmatin contain this metal, apparently in an oxidised state.

2. If, as Liebig asserts, peroxide of iron exists in arterial blood, and carbonate of protoxide of iron in venous blood, almost any dilute acid would be capable of removing it. But this is not the case. Hæmatin properly prepared may be digested with dilute hydrochloric or sulphuric acid for many days without the least diminution in the quantity of the iron. From hæmatin treated in this manner Mulder obtained by combustion 9·49 per cent. of peroxide of iron, which is the constant quantity always left after the combustion of well-prepared hæmatin.

3. The probability that the iron exists in a metallic state is strongly supported by the observation that hydrogen is evolved when a clot of blood is digested in sulphuric acid, and water is added. Mulder suggests that it occurs as an integral constituent of hæmatin in just the same manner that iodine occurs in sponge, sulphur in cystin, or arsenic in the cacodyl series.

4. The amount of hæmatin in the whole mass of the blood is far too inconsiderable to carry a due supply of oxygen to the whole system.

Having thus shown the principal objections to which Liebig's celebrated theory is open, we shall endeavour briefly to explain the rival theory of Mulder. It is a well-known fact, that the protein-compounds are capable of undergoing oxidation when in contact with the oxygen of the air. When a protein-compound becomes oxidised, it assumes a plastic character, that is to say, it has a tendency to become solid and to adhere to solid substances. It has been already stated that the blood-corpuscles are cells, of which the wall consists of a protein-compound named globulin. When a respiration is performed, the exterior layer of such of the corpuscles as are exposed in the lungs to the action of the air, becomes converted into oxidised protein, it becomes whitish and less transparent. This is the state in which the corpuscles exist in arterial blood. As they reach the capillary system, this white exterior layer is employed in the change of material of the body, and is in that way consumed. Having lost this white layer, they again become transparent. The dark colouring substance in the corpuscles of arterial blood, shining through a white layer, must necessarily appear of a bright red tint, as may be shown by pouring dark red blood into a vessel of milky glass.

The fluid part of the blood called the Serum is a transparent fluid, of a light straw-colour tinged with green. The proportion of it to the solid part of the blood, or Clot, differs in different species of animals. There is a strict relation between its relative proportion and the strength and ferocity, or weakness and gentleness of the animal. It is small in proportion to the power and fierceness of the animal, and large in proportion to its weakness and timidity: thus it is small in the carnivorous animals, and large in the hare, sheep, and so on.

Serum has an adhesive consistence and a saline taste. Its characteristic property is that of coagulating by heat and by the application of certain chemical agents. At the temperature of 160° it is converted into a white opaque solid substance, exactly resembling the white of egg when hardened by boiling, being in fact perfectly pure albumen. Serum contains a quantity of uncombined alkali, for it converts the vegetable colours to green, and it holds in solution various earthy and neutral salts. According to M. Le Canu, who has made the most recent chemical analysis of serum, 1000 parts contain—

Water	906·00
Albumen	78·00
Animal Matter soluble in water and alcohol	1·69
Albumen combined with Soda	2·10
Crystallisable Fatty Matter	1·20
Oily Matter	1·00
Hydrochlorate of Soda and Potash	6·00
Subcarbonate and Phosphate of Soda and Sulphate of Potash	2·10
Phosphate of Lime, Magnesia, and Iron, with Subcarbonate of Lime and Magnesia	·91
Loss	1·00
	1000·00

If a mass of coagulated Serum be cut into small pieces and placed in the mouth of a funnel, a thin fluid drains from it, which is called Serosity, and which constitutes the gravy of meat dressed for the table.

According to M. Le Canu the relative proportions of the constituents of Human Blood to each other, as they exist in most individuals, is as follows, this table being the mean of two analyses:—

1000 parts of Human Blood contain—

Water	783·37
Fibrin	2·83
Albumen	67·25
Colouring Matters	126·31
Fatty Matters in various states	5·16
Various undefined Animal Matters and Salts	15·08
	1000·00

The relative proportion of the different constituents of the blood is constantly varying. Thus the quantity of water, according to M. Le Canu, is capable of varying in 1000 parts from 853·135, the maximum, to 778·625, the minimum. In the male the medium quantity is 791·944, in the female 821·764: the watery proportion also varies with the temperament. In the lymphatic temperament, in the male it is 830·566, in the female 803·716; while in the sanguineous it is, in the male 786·584, and in the female it is 793·007.

The proportion of albumen contained in 1000 parts of blood is capable of varying from 78·270, the maximum, to 57·890, the minimum. The quantity of fibrin varies from 1·360 to 7·236, the medium of twenty-two experiments being 4·298. It appeared to be the greatest in the young or middle aged of the sanguineous temperament and in the inflammatory state; and least in the lymphatic constitution, the aged, and those suffering under congestion and hæmorrhage.

The proportion of the red particles varies more remarkably than that of any other constituent of the blood. In sound health the maximum was found to be in 1000 parts of blood 148·450, and the minimum 68·349; the medium 108·399. In the male, the medium quantity is 132·150, in the female 99·169. It varies considerably with the temperament. In the lymphatic temperament, the medium quantity was found to be, in the male 117·667, in the female 116·300; in the sanguineous temperament, in the male 136·497, in the female 126·174. According to this statement there are contained in 1000 parts of blood, in a sanguineous temperament, 19·830 more red particles than in the lymphatic temperament. Both spontaneous hæmorrhage and the artificial abstraction of blood from the body diminish the relative proportion of the red particles far beyond that of any of the other constituents of the blood. This is found on examination of the blood in the female after an excessive loss of blood; and on examining portions of blood taken from the same body after certain intervals, it was found that a first bleeding furnished in 1000 parts of blood, 792·897 of water, 70·210 of albumen, 9·163 of soluble salts and extraneous matter, and 127·73 of red particles; but a third bleeding a few days afterwards in the same patient, a female, gave 834·053 of water, 71·111 of albumen, 7·329 of soluble salts and extraneous matter, and 87·510 of red particles.

According to analyses more recent than those of Le Canu, the following are the ingredients which are found to be present in healthy blood:—

1. Water.
2. Protein-Compounds { Fibrin. Albumen. Globulin. Binoxide and Tritoxide of Protein.
3. Colouring Matters { Hæmatin. Hæmaphæin.
4. Fats. { Cholesterin. Serolin. Red and white Solid Fats containing Phosphorus. Margaric Acid. Oleic Acid.
5. Iron.
6. Salts. { Albuminate of Soda (?). Phosphates of Lime, Magnesia, and Soda. Sulphate of Potash. Carbonates of Lime, Magnesia, and Soda (?). Chlorides of Sodium and Potassium. Lactate of Soda (?). Oleate and Margarate of Soda (?).
7. Gases. { Oxygen. Nitrogen. Carbonic Acid.
8. Urea—a trace.
9. Sugar—a trace (?).

It will be observed that there are notes of interrogation to several of the salts: the presence of these constituents is denied by Enderlin and Liebig's school generally. Their objection is founded on the circumstance, that if these salts were exposed to a red heat, they would become converted into carbonates; and that the ash obtained from the incineration of blood, if examined directly after the operation, does not contain those salts. As these experiments have been performed under Liebig's personal observation, and have been published in his 'Journal,' and as further they apply equally to almost all the other fluids of the animal body, we shall give the leading grounds on which the presence of alkaline carbonates in the ash is disproved, and its alkalinity is otherwise accounted for:—

1. The ash does not effervesce on the addition of an acid.

2. Hot water poured over the ash becomes alkaline; it holds in solution alkaline phosphates and sulphates, chloride of sodium, and sometimes chloride of potassium, but no other salts.

a. On the addition of a neutral solution of nitrate of silver to this fluid, there is a yellow precipitate which is partly soluble in nitric acid; a portion however consisting of chloride of silver remains undissolved. The addition of nitric acid causes no effervescence. On neutralising the acid filtrate with ammonia, a yellow precipitate of tribasic phosphate of silver ($3\ Ag\ O,\ P_2\ O_5$) is thrown down.

b. On treating the aqueous solution of the ash with a solution of chloride of calcium, there is a copious gelatinous precipitate of phosphate of lime ($3\ Ca\ O,\ P_2\ O_5$) which dissolves in nitric acid without effervescence. On treating this acid solution with nitrate of silver, and neutralising with ammonia, the tribasic phosphate of silver is precipitated as before. The addition of the chloride of calcium neutralises the previously alkaline fluid. From 1, we see that the alkaline reaction is not due to the presence of alkaline carbonates; and 2 shows it is not dependent on the presence of free potash or soda, for otherwise the fluid would not be neutralised by the chloride of calcium. Hence the albumen in the blood cannot exist as a soda compound (albuminate of soda); neither can there be alkaline lactates, acetates, nor fatty-acid salts in that fluid. On the above grounds Enderlin conceives that we are justified in assuming that the alkaline reaction of the ash is dependent on the presence of tribasic phosphate of soda ($3\ Na\ O,\ P_2\ O_5$); and as this is the only salt that remains tribasic at a red heat, he concludes that the alkalinity of the blood, as well as of the ash, is dependent on it. The manner in which he accounts for the occurrence of carbonates in the analyses of other chemists is very plausible. On exposing the tribasic phosphate of soda to the atmosphere, it becomes converted into $2\ Na\ O,\ H\ O,\ P_2\ O_5$, and $Na\ O,\ C\ O_2$, or phosphate of soda, in which one atom of the base is replaced by an atom of water and carbonate of soda.

This question regarding the salts actually occurring in the blood is however far from settled, Ludwig having positively denied Enderlin's statements. (Day's 'Report on the Progress of Chemistry,' in Ranking's 'Half-Yearly Abstract of the Medical Sciences,' vol. iii., 1846.)

Generally speaking it is only requisite in the analysis of the blood, to determine a few of the most important constituents; as, for instance, the water, fibrin, blood-corpuscles (globulin and hæmatin), and the solid residue of the serum (the organic portion and the salts). For this purpose we may adopt the following simple plan lately published by Figuier. It is based on the fact made known many years ago by Berzelius, that after the addition of a solution of a neutral salt to defibrinated blood, the globules do not (as before) pass through filtering paper. On the addition of two parts of a solution of sulphate of soda of specific gravity 1.130 to one of blood, Figuier found that the whole of the corpuscles remained on the surface of the filter. The following are the steps of his analysis:—The fibrin is removed by stirring, dried, and weighed; the weight of the corpuscles is ascertained by the method indicated, and that of the albumen by coagulating by means of heat the filtered solution. The proportion of water is known by evaporating a small known weight of the blood. The filter containing the corpuscles should be dipped in boiling water, which removes any sulphate of soda that may be present, and at the same time renders the corpuscles insoluble. Separate and frequently difficult processes are requisite to detect those ingredients which occur in small quantity or only in morbid conditions.

With regard to the distinctions between Arterial and Venous Blood, we have already noticed the circumstance that the external envelope of the blood-corpuscles becomes converted during the act of respiration into oxidised protein, and that the bright-red colour of arterial blood is owing in part to the modifying influence of the white investing membrane. But there is yet another mode in which it acts. The buffy coat, which is the name given to the superimposed layer of fibrin in the clot, is frequently observed on the upper part of the clot in inflammatory diseases as being very apt to curl up and become concave. Now this buffy coat consists, for the most part, of the oxides of protein—of the very same matter with which the blood-corpuscles become invested. For this reason the form assumed by the two laminæ on both sides of the little flat body—the corpuscle—must resemble that of the buffy coat. The tendency to contract and become bi-concave is so strong, that the central portion of the crust becomes entirely depressed. In this form the corpuscles reflect a great deal more light than when, in consequence of the removal of the buffy coat in the capillaries, they have a less bi-concave form.

From four analyses of the blood of horses, Simon deduces the following rule regarding the chemical differences of arterial and venous blood:—"Arterial contains less solid residue generally than venous blood; it contains less fat, less albumen, less hæmatin, less extractive matter and salts, than venous blood. The blood-corpuscles of arterial blood contain less colouring matter than those of venous blood."

The arterial blood was taken from the carotids, and the venous from the jugulars.

In a medical point of view the composition of venous blood is the most interesting, because it is from the veins that blood is almost always taken in disease, and because venous blood can naturally only be compared with venous blood for the purpose of ascertaining any deviations that may occur. The following table represents the mean composition of human venous blood without reference to sex :—

Water	795·278
Solid Constituents	204·022
Fibrin	2·104
Fat	2·346
Albumen	76·660
Globulin	103·022
Hæmatin	6·209
Extractive Matters and Salts	12·012

100 parts of blood-corpuscles contain 5·7 of hæmatin.

Hence the blood contains about 20 per cent. of solid constituents, much more than 0·2 per cent. of fibrin, and about an equal quantity of fat; the blood-corpuscles considerably exceed the albumen in quantity, and contain about 5 or 6 per cent. of colouring matter.

The blood undergoes various modifications in different forms of disease. The extent of these variations is obvious from the following table, drawn up from Simon's 'Animal Chemistry,' vol. i., p. 246.

The Water may vary from	915·0	to	725·0
The Solid Residue „	275·0	to	85·0
The Fibrin „	10·3	to	a trace.
The Fat „	4·3	to	0·7
The Albumen „	131·0	to	55·1
The Globulin „	106·6	to	30·8
The Hæmatin „	8·7	to	1·4
The Extractive Matters and Salts	16·5	to	7·6

The following synopsis will give an idea of the distribution of the constituents of the blood.

Water			790·37	Serum	869·15
Albumen			67·80		
Oxygen			10·98		
Nitrogen					
Carbonic Acid					
Extractive Matter					
Fatty Matter					
Salts					
Colouring Matter					
Fibrin			2·95	Clot	130·85
Hæmatin	2·27	Blood corpuscles	127·90		
Globulin	125·63				
			1000·00		1000·00

It will be seen from the previous account that the blood is one of the most important constituents of the body. It is in fact the prime source of life, and is the great medium through which the constituents of the body pass in their way from the vegetable and mineral kingdoms to become part and parcel of the tissues of the body. The food is taken up from the intestines [FOOD] by the lacteals, and is converted into blood before it is appropriated in the tissues of the body. The correspondence between the flesh or tissues of the body and the blood may be seen in the following statement of the ultimate composition of the two.

	Flesh.	Blood.
Carbon	51·86	51·96
Hydrogen	7·58	7·25
Nitrogen	15·03	15·07
Oxygen	21·30	21·30
Ash	4·23	4·42

The blood is not only the source whence the tissues are supplied with the fresh materials for their growth, but it is the means by which effete matters are thrown off from the system. The constituents of the bile, the urine, the perspiration, the expired air from the lungs, are all found in the blood, and separated from it by the liver, kidneys, skin, and lungs. The changes involved in the formation of these excretions are some of them important to life, as that of carbonic acid gas during respiration [RESPIRATION], which is attended with the development of animal heat.

Any interruption or impediment to the performance of the functions of the blood is attended with disease. This has long been suspected, but it is only since the employment of the microscope and chemical analysis that any advance has been made in studying the relation of abnormal conditions of the blood to particular diseases of the body.

(Hunter, *On the Blood;* Sharpey, *Quain's Anatomy,* vol. i.; Simon, *Animal Chemistry,* translated by Day; Milne-Edwards, article *'Blood,'* in *Cyclopædia of Anatomy and Physiology;* Lehmann, *Physiological Chemistry,* translated by Day; Liebig, *Animal Chemistry;* Carpenter, *Human Physiology*).

BLOOD-HOUND, the name of a hound celebrated for its exquisite scent and unwearied perseverance, qualities which were taken advantage of, by training it not only to the pursuit of game, but to the chase of man. A true Blood-Hound (and the pure blood is rare) stands about 28 inches in height, muscular, compact, and strong; the forehead is broad, and the face narrow towards the muzzle; the nostrils are wide and well developed; the ears are large, pendulous, and broad at the base; the aspect is serene and sagacious; the tail is long, with an upward curve when in pursuit, at which time the hound opens with a voice deep and sonorous, that may be heard down the wind for a very long distance.

The colour of the true breed is stated to be almost invariably a reddish-tan, darkening gradually towards the upper parts till it becomes mixed with black on the back; the lower parts, limbs, and tail being of a lighter shade, and the muzzle tawny. Pennant adds, "a black spot over each eye," but the blood-hounds in the possession of Thomas Astle, Esq. (and they were said to have been of the original blood), had not these marks. Some, but such instances were not common, had a little white about them, such as a star in the face, &c. The better opinion is, that the original stock was a mixture of the deep-mouthed southern hound, and the powerful old English stag-hound.

Gervase Markham, in his 'Maison Rustique,' speaking of hounds, says :—"The baie-coloured ones have the second place for goodnesse, and are of great courage, ventring far, and of a quicke scent, finding out very well the turnes and windings . . . . . they runne surely, and with great boldnesse, commonly loving the stagge more than any other beast, but they make no account of hares. It is true, that they be more head-strong and harde to reclaime than the white, and put men to more paine and travaill about the same. The best of the fallow sort of dogges are those which are of a brighter haire, drawing more unto the colour of red, and having therewithall a white spot in the forehead, or in the necke, in like manner those which are all fallow: but such as incline to a light yellow colour, being graie or blacke spotted, are nothing worth: such as are trussed up and have dewclawes, are good to make bloud-hounds."

Our ancestors soon discovered the infallibility of the Blood-Hound in tracing any animal, living or dead, to its resting place. To train it the young dog acccompanied by a staunch old hound was led to the spot whence a deer or other animal had been taken on for a mile or two; the hounds were then laid on and encouraged, and after hunting this 'drag' successfully, were rewarded with a portion of the venison which composed it. The next step was to take the young dog, with his seasoned tutor, to a spot whence a man whose shoes had been rubbed with the blood of a deer had started on a circuit of two or three miles: during his progress the man was instructed to renew the blood from time to time, to keep the scent well alive. His circuit was gradually enlarged at each succeeding lesson, and the young hound, thus entered and trained, became at last fully equal to hunt by itself, either for the purposes of woodcraft, war, or 'following gear,' as the pursuit after the property plundered in a border foray was termed. Indeed, the name of this variety of *Canis domesticus,* to which Linnæus applied the name of *sagax,* cannot be mentioned without calling up visions of feudal castles with their train of knights and warders, and all the stirring events of those old times when the best tenure was that of the strong hand.

Sir Walter Scott gives a striking reality to the scene, when he makes the moss-trooper, William of Deloraine, who had "baffled Percy's best blood-hounds," allude to the pleasure of the chace, though he himself was the object of pursuit, in pronouncing his eulogy over Richard Musgrave.

In the same 'Lay of the Last Minstrel' there is one of the best poetical descriptions of the blood-hound in action, if not the best; for though Somerville's lines may enter more into detail, they want the vivid animation of the images brought absolutely under the eye by the power of Scott, where the "noble child," the heir of Branksome, is left alone in his terror.

Indeed this feudal dog is frequently introduced by our poet, from his ballads, where Smaylho'me's Lady gay, wooing the Phantom Knight to come to her bower, in the 'Eve of St. John,' tells the spectre that she will "chain the blood-hound," down to that grand moonlight scene in the 'Legend of Montrose,' where Dalgetty and Ranald of the Mist are traced to their wood-girt retreat after their escape from Argyle's dungeons.

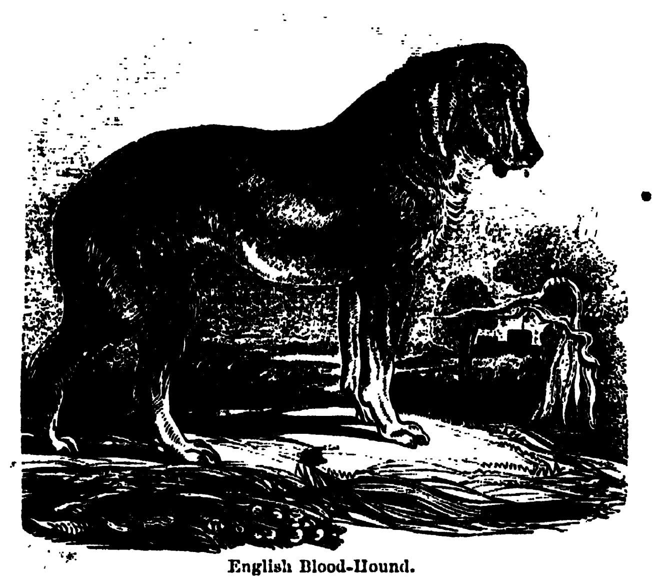
The pursuit of border forayers was called the 'hot-trod.' The 'harried' party and his friends followed the marauders with blood-hound and bugle-horn, and if his dog could trace the scent into the opposite kingdom he was entitled to pursue them thither.

Sir Walter Scott states that the breed was kept up by the Buccleuch family on their border estates till within the 18th century, and records the following narrative :—"A person was alive in the memory of man who remembered a blood-hound being kept at Eldinhope, in Ettricke Forest, for whose maintenance the tenant had an allowance of meal. At that time the sheep were always watched at night. Upon one occasion, when the duty had fallen upon the narrator, then a lad, he became exhausted with fatigue, and fell asleep upon a bank, near sun-rising. Suddenly he was awakened by the tread of horses, and saw five men well mounted and armed ride briskly over the edge of the hill. They stopped and looked at the flock; but the day was too far broken to admit the chance of their carrying any of them off. One of them, in spite, leaped from his horse, and coming to the shepherd seized him by the belt he wore round his waist; and setting his foot upon his body pulled it till it broke, and carried it away with him. They rode off at the gallop; and the shepherd giving the alarm, the blood-hound was turned loose, and the people in the neighbourhood alarmed. The marauders, however, escaped, notwithstanding a sharp pursuit. This circumstance serves to show how very long the license of the Borderers continued in some degree to manifest itself."

This, perhaps, is the last instance of an attempted 'Border foray' on record. The times were changed. The nobles had ceased to pride themselves on their ignorance of all the arts save the art of war, and to make it matter of thanksgiving that they knew not how to use the pen. Civilisation advanced as learning was diffused, till the law of the strongest no longer prevailed against the law of the land. The Blood-Hound, from the nobler pursuit of heroes and knights, 'minions of the moon,' who swept away the cattle and goods of whole districts, marking the extent of their 'raid' by all the horrors of fire and sword, sank to the tracker of the deer-stealer and petty felon. About a century and a quarter ago, when deer-stealing was a common crime, the park-keepers relied upon their blood-hounds principally for detecting the thief; and so adroit were these dogs, that when one of them was fairly laid on, the escape of the criminal was with good reason considered to be all but impossible. Even now the breed still lingers about some of the great deer-parks; and many of our readers will remember the noble specimen at Richmond Park, bearing the name of Procter, and the admirable study of his head engraved by T. Landseer from a painting by his brother Edwin. Another of this race has been perpetuated by Sir Edwin Landseer. It belonged to Jacob Bell, Esq., and was killed by jumping out of a window, and its accidental death is perpetuated by the artist having drawn it after death as though sleeping.

This noble variety is now only kept as an object of curiosity and ornament; for its services have long since been superseded by the justice's warrant and the police-officer. We find it, indeed, recorded about 50 years ago, that "the Thrapston association for the prevention of felons in Northamptonshire have provided and trained a blood-hound for the detection of sheep-stealers. To demonstrate the unerring infallibility of this animal a day was appointed for public trial; the person he was intended to hunt started, in the presence of a great concourse of people, about 10 o'clock in the forenoon, and at 11 o'clock the hound was laid on. After a chase of an hour and a half, notwithstanding a very indifferent scent, the hound ran up to a tree in which he was secreted, at the distance of 15 miles from the place of starting, to the admiration and perfect satisfaction of the very great number assembled upon the occasion." But this may be considered more in the light of a proceeding 'in terrorem' than anything else.

Strong and hardy as the Blood-Hound seems to be, it is unable, apparently, to encounter a low temperature. Mr. Lloyd, in his 'Field Sports,' relates that one presented to him by Mr. Otway Cave was entirely paralysed by the piercing cold of the northern regions which were the scene of his exploits.



English Blood-Hound.

Cuban Blood-Hound.—The reputation which this variety has obtained for sagacity and fierceness, and the share that the terror of its name had in extinguishing the last Maroon war in Jamaica, render it an object of some interest. In 1733 these Maroons had become very troublesome, and the Assembly, among other plans for suppressing them, appointed garrisons, from whose barracks excursions were from time to time made against the insurgents. "Every barrack," says Bryan Edwards, "was also furnished with a pack of dogs, provided by the churchwardens of the respective parishes, it being foreseen that these animals would prove extremely serviceable, not only in guarding against surprises in the night but in tracking the enemy." The tiresome war went on however, till at last articles of pacification with the Maroons of Trelawney town were concluded on the 1st of March, 1738. This alliance continued, not without frequent complaints of the conduct of the Maroons, till July, 1795, when two of these people from Trelawney town, having been found guilty by a jury of stealing some pigs, were sentenced to receive thirty-nine lashes each, and the sentence was executed. On their return to Trelawney town their account drove the Maroons into open revolt, and a bloody and successful war was waged by these savages against the whole force that the government could direct against them.

At last the Assembly, in the month of September, remembering the expedient of employing dogs previous to the treaty of 1738, resolved to send to the island of Cuba for 100 blood-hounds, and to engage a sufficient number of Spanish huntsmen to direct their operations. The employment, according to Edwards, to which these dogs are generally put by the Spaniards is the pursuit of wild bullocks, which they slaughter for the hides; and the great use of the dogs is to drive the cattle from such heights and recesses in the mountainous parts of the country as are least accessible to the hunters. This determination of the Assembly was not made without some opposition. After much discussion it was determined to send for the dogs, and at last after several delays the commissioner, who had been dispatched to the Havanna, arrived at Montego Bay on the 14th of December with forty chasseurs, or Spanish hunters, chiefly people of colour, and about 100 Spanish dogs.

Dallas, in his 'History of the Maroons,' gives the following account of the first appearance of these dogs before the commander-in-chief:—"Anxious to review the chasseurs, General Walpole left head-quarters the morning after they were landed before day-break, and arrived in a post-chaise at Seven Rivers, accompanied by Colonel Skinner, whom he appointed to conduct the intended attack. Notice of his coming having preceded him, a parade of the chasseurs was ordered; and they were taken to a distance from the house, in order to be advanced when the general alighted. On his arrival the commissioner having paid his respects was desired to parade them. The Spaniards soon appeared at the end of a gentle acclivity, drawn out in a line containing upwards of forty men, with their dogs in front unmuzzled, and held by cotton ropes. On receiving the command 'fire,' they discharged their fusils and advanced as upon a real attack. This was intended to ascertain what effect would be produced on the dogs if engaged under a fire of the Maroons. The volley was no sooner discharged than the dogs rushed forward with the greatest fury, amid the shouts of the Spaniards, who were dragged on by them with irresistible force. Some of the dogs maddened by the shout of attack, while held back by the ropes, seized on the stocks of the guns in the hands of their keepers and tore pieces out of them. Their impetuosity was so great that they were with difficulty stopped before they reached the general, who found it necessary to get expeditiously into the chaise from which he had alighted; and if the most strenuous exertions had not been made to stop them, they would most certainly have seized upon his horses."

This scene was well got up, and it had its effect. General Walpole was ordered to advance on the 14th of January following, with his Spanish dogs in the rear. Their fame however had reached the Maroons, and the general had penetrated but a short way into the woods when a supplication for mercy was brought from the enemy, and 260 of them soon afterwards surrendered on no other condition than a promise of their lives.

It is stated that these dogs when properly trained will not kill or harm the pursued unless they are resisted. "On reaching a fugitive they [illegible] him till he stops, and then couch near him, terrifying him with a ferocious growling if he stirs. They then bark at intervals to give notice to the chasseurs, till they come up and secure their prisoner."

Dallas however, who had his information from the commissioner himself, William Dawes Quarrell, to whom his work is dedicated, gives a description and representation of one of these Spanish chasseurs with his dogs; and he relates the following instances of the strength and determined ferocity of the latter:—

"The party had scarcely erected their huts when the barking of a dog was heard near them. They got immediately under arms, and proceeding in the direction of the sound discovered a negro endeavouring to make his escape. One of the Spanish dogs was sent after him. On coming up the negro cut him twice with his muschet,* on which the dog seized him by the nape of the neck and secured him. He proved to be a runaway—said that he and two other negroes had deserted the Maroons a few days before, and that the party was at a great distance from the town, but that he would conduct them to it by noon next day."

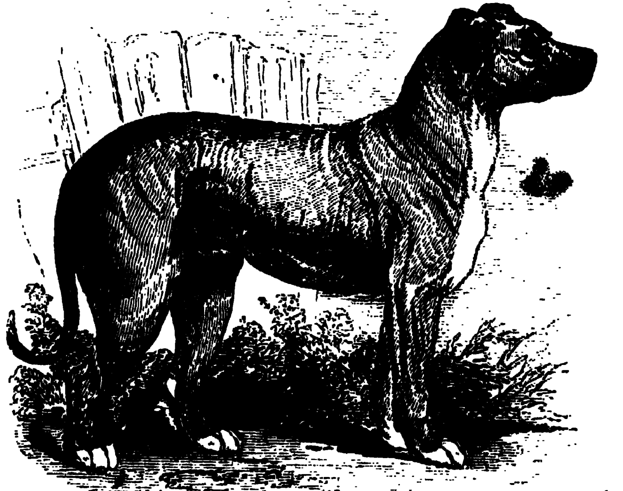
In the next anecdote recorded by Dallas the attack was fatal both to the unhappy object of it and to the dog:—"One of the dogs that had been unmuzzled to drink when there was not the least apprehension of any mischief, went up to an old woman who was sitting attending to a pot in which she was preparing a mess. The dog smelled at it and was troublesome; this provoked her; she took up a stick and began to beat him, on which he seized on her throat, which he would not let go till his head was severed from his body by his master. The windpipe of the woman being much torn, she could not be saved."

---

* A long straight muschet, or couteau, longer than a dragoon's sword, and twice as thick, something like a flat iron bar sharpened at the lower end, of which about eighteen inches are as sharp as a razor. The point is not unlike the old Roman sword. Such is Dallas's description of the chasseur's muschet.

Chasseur with Cuban Blood-Hounds.

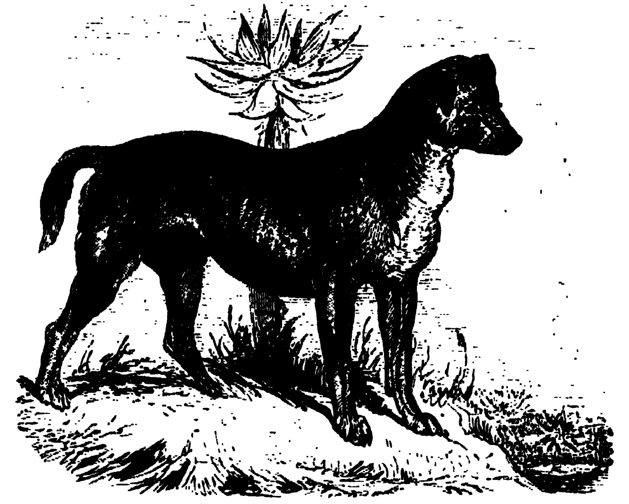
A dog and a bitch, said to be of the true Cuban Blood-Hound breed, were some years ago brought to this country, where soon after their arrival the bitch littered ten pups, one of them deformed. The figure here given is from one of these pups, which had not attained its full growth. They are shorter on their legs than the English variety; the muzzle is shorter, and the animal is altogether smaller, with less of the hound about it than the English Blood-Hound has; the height is about two feet; the colour generally tawny, with black about the muzzle, or brindled like some of the Ban-Dogs. They show great attachment, and are very gentle till seriously provoked, and then their ferocity is alarming.



Cuban Blood-Hound.

In Cuba the common employment of these dogs was to traverse the country in pursuit of murderers and other felons, and an extraordinary proof of their activity is recorded by Dallas, who states that the event occurred about a month before the arrival of the commissioner at the Havanna. A fleet from Jamaica, under convoy to Great Britain, passing through the Gulf of Mexico, beat up on the north side of Cuba. One of the ships, manned with foreigners, chiefly renegado Spaniards, being a dull sailer, and consequently lagging astern, standing in with the land at night, was run on shore, the captain, officers, and the few British hands on board murdered, and the vessel plundered by the Spanish renegadoes. The part of the coast on which the ship was stranded being wild and unfrequented, the assassins retired with their booty to the mountains, intending to penetrate through the woods to some remote settlements on the south side, where they hoped to secure themselves and elude all pursuit. Early intelligence of the crime however had been conveyed to the Havanna, and the assassins were pursued by a detachment of twelve of the Chasseurs del Rey with their dogs. In a few days the criminals were all brought in and executed, not one of them being in the least hurt by the dogs when captured.

African Blood-Hound.—On his return from Africa the late Colonel Denham, then major, presented two dogs and a bitch of this variety to the royal menagerie in the Tower, which, under the care of the keeper, Mr. Cops, then contained a very choice collection of animals, recorded in that interesting publication 'The Tower Menagerie, London, 8vo, 1829. The Major informed Mr. Cops that with them he hunted the gazelle, and that they displayed great cunning, frequently quitting the circuitous line of scent for the purpose of cutting off a double, and recovering the scent again with ease. They would hit off and follow a scent after a lapse of two hours from the time when the animal had been on the spot, and this delicacy of nose had not escaped observation, for they were applied to nearly the same purposes as the other varieties here mentioned, and were commonly employed in Africa to trace a flying enemy to his retreat. It is well remarked in the work last above mentioned that for symmetry and action they were perfect models, and a regret is expressed that in consequence of their not having shown any disposition to perpetuate their race, though they had at the time of making the observation been three years in England, there appeared to be no chance of crossing our pointers with this breed. We agree with the writer in thinking that this blood so introduced would be a very valuable acquisition. It was remarked that of the three in the Tower the males were very mild, but the female was of a very savage disposition.



African Blood-Hound.

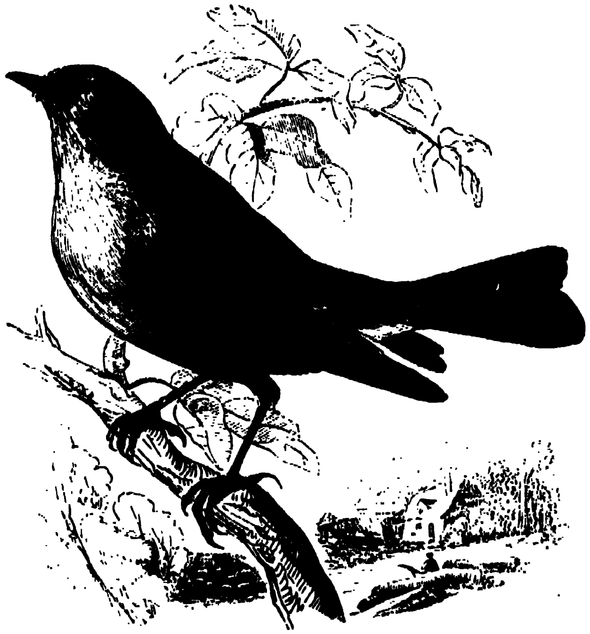
BLOODSTONE, also called *Heliotrope*, is a deep green stone—a jaspery variety of Quartz. It has obtained its name from being spotted with red so as to resemble drops of blood. In addition to silica it contains oxide of iron and clay, which are mechanically introduced, and in this way the red spots are produced. In the royal collection at Paris there is a bust of Christ in this stone, so managed that the red spots represent drops of blood. (Dana, *Mineralogy*.)

BLOOD-VESSELS. The blood from which the tissues of the body obtain the material of their nourishment is conveyed from one part of the body to another by means of branched tubes which are named Blood-Vessels. It is carried along these vessels by the impulse given by the action of the Heart. [HEART.] The vessels which carry the blood from the heart are called Arteries. [ARTERY.] Those which return the blood to the heart are named Veins. [VEIN.] Whilst a very generally diffused network of Blood-Vessels exist, connecting the arteries and veins, which are called Capillaries. [CAPILLARY VESSELS.]

The Blood-Vessels, whatever may be their ultimate destination, seem to originate in the same manner. Observations on this subject have been made by Schwann and Kölliker in Germany, and by Professor Paget in this country. The observations of the two former were made on the development of the vessels in the germinal membrane of the egg, and on the capillary blood-vessels of the tail of the larva of a frog. Mr. Paget's observations were made on the tissues of the fœtal sheep. According to these observers it appears that these vessels originate from nucleated cells similar to those which at first constitute the different parts of the embryo. The cell-wall or external envelope of these cells shoots out into slender pointed processes, such as is seen in the forms of stellate vegetable tissue. The projections from neighbouring cells encounter each other, and becoming organically united, the intervening walls between the two projections are absorbed, and thus a continuous tube is produced. In cases where new vessels are produced in the neighbourhood of old ones, the stellate cells are formed in the new part, and projections are formed in the old capillary vessels which unite with the new ones, and thus the circulation is re-established. The projections when first united are solid and very slender, but eventually the intervening substance disappears and the vessels attain a uniform calibre. In growing parts where the web of vessels is kept up, new ones are constantly being added by the development of stellate cells in the interstices of the previous web. Whilst the capillaries early attain the development at which they remain, those vessels which are to become arteries or veins on either side of the capillary vessels go on increasing in size till they acquire the special membranes or coats which distinguish these parts of the circulating system. This explanation seems however only applicable to the smaller veins and arteries, as the observations of Kölliker would seem to show that the larger Blood-Vessels may take their origin in the same manner as the heart, in which organ there is first an agglomeration of cells, the interior ones of which become soft, and at last disappear, whilst the outside ones become firmer and constitute the outer walls. On this subject further observations are wanting.

(Sharpey, *Quain's Elements of Anatomy;* Schwann, *Microscopical Researches into the Accordance in the Structure and Growth of Animals and Plants,* translated by H. Smith; Kölliker, *Handbuch der Gewebelehre der Menschen;* Paget, *Supplement to Müller's Physiology,* by Baley and Kirkes.)

BLUE-BIRD, the American name for the *Motacilla sialis* of Linnæus, *Sylvia sialis* of Wilson, *Saxicola sialis* of Bonaparte, *Ampelis sialis* of Nuttall, and *Erythaca* (*Sialia*) *Wilsonii* of Swainson.



Blue-Bird (*Motacilla sialis*).

Like our red-breast this harbinger of spring to the Americans "is known to almost every child, and shows," says Wilson, "as much confidence in man by associating with him in summer, as the other by his familiarity in winter.

"So early as the middle of February, if the weather be open, he usually makes his appearance about his old haunts, the barn, orchard, and fence-posts. Storms and deep snows sometimes succeeding, he disappears for a time; but about the middle of March is again seen accompanied by his mate visiting the box in the garden or the hole in the old apple-tree, the cradle of some generations of his ancestors." . . . . "When he first begins his amours," says a curious and correct observer, "it is pleasing to behold his courtship, his solicitude to please and to secure the favour of his beloved female. He uses the tenderest expressions, sits close by her, caresses and sings to her his most endearing warblings. When seated together if he espies an insect delicious to her taste he takes it up, flies with it to her, spreads his wing over her, and puts it in her mouth."

The food of the Blue-Bird consists principally of insects, particularly large beetles and other *Coleoptera,* frequently of spiders, and sometimes of fruits and seeds.

The nest is built in holes in trees and similar situations. The bird is very prolific, for though the eggs, which are of a pale-blue colour, seldom exceed six, and are more frequently five in number, two and sometimes three broods are produced in a season.

Its song is cheerful, continuing with little interruption from March to October, but is most frequently heard in the serene days of the spring.

With regard to its geographical distribution, Catesby says:—"These birds are common in most parts of North America, for I have seen them in Carolina, Virginia, Maryland, and the Bermuda Islands." Wilson gives the United States, the Bahamas, Mexico, Brazil, and Guyana, as its localities. About November it takes its departure from the United States.

The whole upper part of the bird, which is about 7¼ inches long, is of a rich sky-blue shot with purple; the bill and legs are black; shafts of the wing and tail feathers black; throat, neck, breast, and sides, partially under the wings, reddish chestnut; wings dusky-black at the tips; belly and vent white. The female is duller in its colours. It is said to be much infested with tape-worms.

BLUE-BOTTLE. [CENTAUREA.]

BLUE-BREAST, one of the English names for this pretty bird, which, as Bechstein observes, may be considered as the link between the Redstart and Common Wagtail, having strong points of resemblance to both. It is also called Blue-Throated Robin and Blue-Throated Redstart. It is the Gorge-Bleue of the French, the Blaukehlein of the Germans, Petto Turchino of the Italians, the *Cyanecula* of Brisson, *Motacilla Suecica* of Linnæus, *Sylvia cyanecula* of Meyer, the Blue-Throated Warbler and *Sylvia Suecica* of Latham, *Phœnicena Suecica* of Gould, *Ficedula Suecica* of Eyton.

Blue-Breast (*Motacilla Suecica*).

According to Temminck the Blue-Breast is found in the same countries which are inhabited by the Red-Breast, and particularly on the borders of forests, but is more rare in France and Holland than the latter bird. Bonaparte notes it as accidental and very rare in the neighbourhood of Rome, and as only appearing in severe winters. In England it is very rarely seen. Yarrell in his 'British Birds' records four instances of its having been shot in England.

The food of the Blue-Breast, according to Temminck, consists of flies, the larvæ of insects, and worms. Bechstein says that it also eats elder-berries. It is one of those unfortunate birds which is called by some a Beccafico. The nest is said to be built in bushes and in the holes of trees. The eggs, of a greenish-blue, are six in number.

The following is Bechstein's accurate description of the male:—"Its length is 5¼ inches, of which the tail occupies 2¼ inches. The beak is sharp and blackish, yellow at the angles; the iris is brown; the shanks are 14 lines high, of a reddish-brown, and the toes blackish; the head, the back, and the wing-coverts are ashy-brown, mottled with a darker tint; a reddish-white line passes above the eyes; the cheeks are dark-brown, spotted with rust-red and edged at the side with deep ash-gray; a brilliant sky-blue covers the throat and half-way down the breast; this is set off by a spot of the most dazzling white, the size of a pea, placed precisely over the larynx, which enlarging and diminishing successively by the movement of this part when the bird sings produces the most beautiful effect. The blue passes into a black band, and the latter into a fine orange; the belly is dusky-white, yellowish towards the vent; the thighs and sides are reddish; the quill-feathers dark-brown; the tail-feathers red at the base, and half the summit black; the two intermediate ones are entirely dark-brown. Some males have two little white spots on the throat, some even have three while others have none; these latter are probably very old, for I have observed that as the bird grows older the blue deepens and the orange band becomes almost maroon."

The female resembles the male in the upper parts. On each side of the neck is a blackish longitudinal streak passing on the upper parts of the breast into a large blackish space tinged with ash-colour. On the middle of the neck is a great spot of pure white. Flanks clouded with olive, the rest of the lower parts white. The very old females have the throat sometimes of a very bright blue. This is probably a sign that they have done laying, and are putting on the plumage of the male. Bechstein says that the females when young are of a celestial blue tint on the sides of the throat, which deepens with age and forms the two longitudinal lines.

The young, according to Temminck, are brown spotted with white, and have all a large white space upon the throat. "Its song," says Bechstein, "is very agreeable; it sounds like two voices at once; one deep, resembling the gentle humming of a violin string, the other the soft sound of a flute."

BLUMENBA'CHIUM, a genus of Fossil Alcyonoid *Polypiaria*, proposed by Dr. König.

BLYSMUS, a genus of plants belonging to the natural order *Cyperaceæ*. The glumes are fertile, the outermost the largest and empty; bristles three to six; style not thickened at the base, persistent, but plano-convex, tipped with the undilated base of the style; the spikelets bracteated, alternate, forming a close distichous compound terminal spike. Two species of this inconspicuous genus are found in Great Britain. *B. compressus* is found in boggy pastures in England and Scotland. *B. rufus* inhabits marshes near the sea on the northern and western coasts. (Babington, *Manual.*)

BOA, a name applied to various forms of large Snakes. The species to which this name has been given are mostly included in the family *Boidæ*. [BOIDÆ.]

BOAR-FISH. [CAPROS.]

BOA'RMIA, a genus of Moths of the family *Geometridæ*. All the species of this genus are of an ashy colour, or white minutely dotted with brown, and adorned with several fasciæ of a deeper colour; the antennæ of the males, instead of being pectinated, a character common in the *Geometridæ*, are pilose; palpi short, clothed with short scales, three-jointed, the two basal joints of equal length, the terminal joint concealed; antennæ simple in the females; thorax small, velvety; wings, when at rest, placed horizontally; body slender in the males, in the females shorter and more robust.

Mr. Stephens, in his 'Illustrations of British Entomology,' enumerates seven species of this genus, most of which are found in woods in the neighbourhood of London.

BOAT-BILL, the English name for the genus *Cochlearius* of Brisson, *Cancroma* of Linnæus, Les Savacous of the French.

This genus of the family *Ardeidæ* (Heron-like Birds) would approach quite closely, as Cuvier observes, to the herons [ARDEA] in regard to their bill and the kind of food which it indicates, were it not for the extraordinary form of that organ, which is nevertheless, when closely observed, the bill of a heron or a bittern very much flattened out. This bill is of an oval form, longer than the head, very much depressed, and not unlike the bowls of two spoons placed one upon the other, with the rims in contact. The mandibles are strong, with sharp edges, and dilated towards the middle. The upper mandible is carinated, and hooked at its point, which has a small tooth or notch on each side of it. The lower mandible is flatter than the upper, straight, membranous in the centre, and terminated by a sharp point. The nostrils are oblique, longitudinal, and closed.

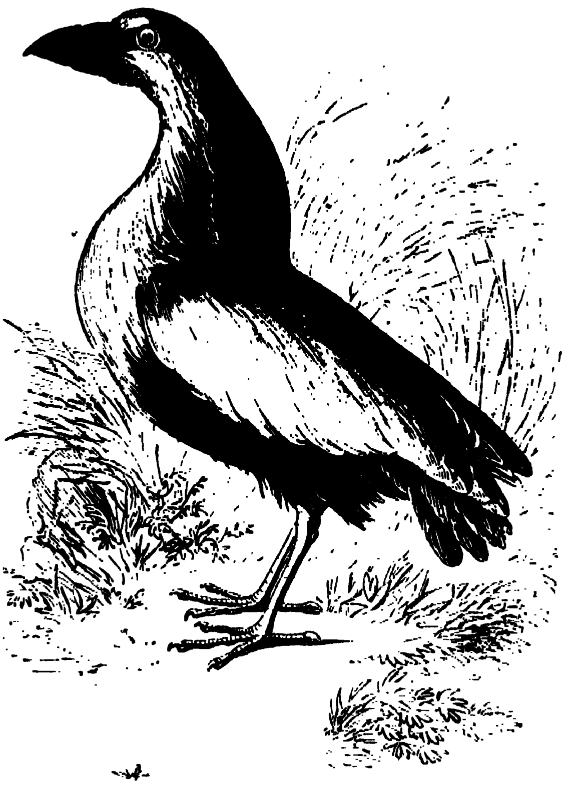
The first quill is short; the five next are the longest. The feet are furnished with four toes, all long, and almost without membranes.

Though zoologists have described more than one species, it appears that they may be referred to the only species yet known, *Cochlearius fuscus* of Brisson, *Cancroma cochlearia* of Linnæus, Le Savacou of Buffon, the differences on which *Cancroma cancrophaga* (Linnæus, &c.) is founded not being allowed to be specific. Leach, in his 'Zoological Miscellany,' figures and describes the common Boat-Bill under the title of *Cancroma vulgaris*, but assigns no reason for altering the specific name given by Linnæus.

The common Boat-Bill is about the size of a domestic hen. In the male, the forehead and upper parts of the neck and breast are dirty white; the back and lower part of the belly rusty-reddish; the bill is black, and the legs and feet are brown. From the head depends a long crest of black feathers, falling backwards. The female has the top of the head black, without the elongated crest; the back and the belly rusty-reddish; the wings gray; the forehead and rest of the plumage white; and the bill, legs, and feet, brown.

"This species," says Latham, in his 'Synopsis,' "for I refer all that has been treated of above to one only, inhabits Cayenne, Guyana, and Brazil, and chiefly frequents such parts as are near the water. In such places it perches on the trees which hang over the streams, and, like the kingfisher, drops down on the fish which swim beneath. It has been thought to live on crabs likewise, whence the Linnæan name; but this is not clear, though it cannot be denied; yet we are certain that fish is the most common, if not the only food."

Lesson ('Manuel') says, "The Boat-Bill perches on trees by the side of rivers, where it lives on fish, and not on crabs, as its name indicates;" and speaks of it as inhabiting the inundated savannahs of South America, and as being especially common in Guyana.



Boat-Bill (*Cancroma cochlearia*), male.

Leach ('Zoological Miscellany') says that it inhabits Southern America, and feeds on fishes, *vermes*, and *crustacea*, in quest of which it is continually traversing the borders of the sea.

Cuvier ('Règne Animal') says that it inhabits the warm and moist parts of South America, and perches on trees by the side of rivers, whence it precipitates itself on the fish which afford its ordinary nourishment.

BOB-O-LINK, or BOB-LINK, the usual name by which the Rice-Bird, or Reed-Bird—the Skunk-Bird, Seecawk-Potheesew of the Cree Indians, the Rice-Bunting of Pennant and of Wilson, Rice-Troopial of authors, *Hortulanus Carolinensis* of Catesby, *Emberiza orizyvora* of Linnæus, *Icteris agripennis* of Bonaparte, *Dolichonyx orizyvorus* of Swainson—is known in the United States.

Bob-o-Link (*Dolichonyx orizyvorus*).

Catesby, Wilson, Audubon, and Nuttall give the most complete accounts of this well-known bird:—"The whole continent of America," says the latter, "from Labrador to Mexico and the great Antilles, are the occasional residence of this truly migratory species. About the middle of March, or beginning of April, the cheerful Bob-o-Link makes his appearance in the southern extremity of the United States, becoming gradually arrayed in his nuptial livery, and accompanied by troops of his companions, who often precede the arrival of their more tardy mates." (Bartram's 'Travels,' p. 295, edit. Lond.) "Their wintering resort appears to be rather the West Indies than the tropical continent, as their migrations are observed to take place generally to the east of Louisiana, where their visits are rare and irregular." (Audubon's 'Ornithological Biography,' vol. i. p. 283.) At this season also they make their approaches chiefly by night, obeying as it were more distinctly the mandates of an overruling instinct, which prompts them to seek out their natal regions; while in autumn their progress, by day only, is alone instigated by the natural quest of food. About the 1st of May the meadows of Massachusetts begin to re-echo their lively ditty. At this season in wet places, and by newly-ploughed fields, they destroy many insects and their larvæ; but while on their way through the southern states they cannot resist the temptation of feeding on the early wheat and tender barley. According to their success in this way parties often delay their final northern movement as late as the middle of May, so that they appear to be in no haste to arrive at their destination at any exact period. The principal business of their lives however, the rearing of their young, does not take place until they have left the parallel of the 40th degree. In the savannahs of Ohio and Michigan, and the cool grassy meadows of New York, Canada, and New England, they fix their abode, and obtain a sufficiency of food throughout the summer without molesting the harvest of the farmer until the ripening of the latest crops of oats and barley, when in their autumnal and changed dress, hardly known now as the same species, they sometimes show their taste for plunder, and flock together like the greedy and predatory blackbirds.

The song of the male generally ceases about the first week in July, and about the same time his variegated dress, which from a resemblance in its colours to that of the quadruped obtained for it the name of 'Skunk-Bird' among the Cree Indians, is exchanged for the sombre hues of the plumage of the female. The author above quoted thus describes the autumnal migration:—

"About the middle of August, in congregating numbers, divested already of all selective attachment, vast foraging parties enter New York and Pennsylvania on their way to the south. Here along the shores of the large rivers, lined with floating fields of the Wild Rice (*Zizania*), they find an abundant means of subsistence during their short stay; and as their flesh, now fat, is little inferior to that of the European ortolan, the reed- or rice-birds, as they are then called in their sparrow dress, form a favourite sport for gunners of all descriptions, who turn out on the occasion and commit prodigious havoc among the almost silent and greedy roosting throng. The markets are then filled with this delicious game, and the pursuit, both for success and amusement along the picturesque and reedy shores of the Delaware and other rivers, is second to none but that of rail-shooting. As soon as the cool nights of October commence, and as the wild rice-crops begin to fail, the reed-birds take their departure from Pennsylvania and New Jersey, and in their further progress through the southern states they swarm in the rice-fields; and before the crop is gathered they have already made their appearance in the islands of Cuba and Jamaica, where they also feed on the seeds of the Guinea Grass (*Sorghum*), becoming so fat as to deserve the name of 'Butter-Birds,' and are in high esteem for the table."

Catesby, under the name of Caroline Ortolan, gives the following interesting account of the Rice-Bird, from which it appears that the damage done to the farmer by this comparatively weak agent is very great:—

"In the beginning of September, while the grain of rice is yet soft and milky, innumerable flights of these birds arrive from some remote parts to the great detriment of the inhabitants. In 1724 an inhabitant near Ashley River had forty acres of rice so devoured by them that he was in doubt whether what they had left was worth the expense of gathering in. They are esteemed in Carolina the greatest delicacy of all other birds. When they first arrive they are lean, but in a few days become so excessively fat that they fly sluggishly and with difficulty, and when shot frequently burst with the fall. They continue about three weeks, and retire by the time the rice first begins to harden. There is something so singular and extraordinary in this bird that I cannot pass it over without notice. In September, when they arrive in infinite swarms to devour the rice, they are all hens, not being accompanied with any cock. Observing them to be all feathered alike, I imagined they were young of both sexes not perfected in their colours; but by opening some scores prepared for the spit I found them to be all females, and that I might leave no room for doubt repeated the search often on many of them, but could never find a cock at that time of the year. Early in the spring both cocks and hens make a transient visit together, at which time I made the like search as before, and both sexes were plainly distinguishable. . . . . In September, 1725, lying upon the deck of a sloop in a bay at Andros Island, I and the company with me heard three nights successively flights of these birds (their note being plainly distinguishable from others) passing over our heads northerly, which is their direct way from Cuba to Carolina; from which I conceive, after partaking of the earlier crop of rice at Cuba, they travel over sea to Carolina for the same intent, the rice there being at that time fit for them."

Sir John Richardson says that the 54th parallel, which it reaches in June, appears to be the most northern limit of the Bob-o-Link, and gives a description of a male in its nuptial dress, which was killed on the Saskatchewan in that month in the year 1827.

Swainson places it as a genus of his third sub-family, *Agelainæ*, in the third or aberrant group of his *Sturnidæ*.

Grassy meadows are the spots usually selected by the bird for its nest, which is made on the ground, generally in some slightly depressed spot, of withered grass, so carelessly bedded together as scarcely to be distinguishable from the neighbouring parts of the field. Here five or six eggs of purplish-white, blotched all over with purplish, and spotted with brown round the larger end, are laid.

The length of the Bob-o-Link is about 7½ inches. The male in his nuptial dress has the head, fore part of the back, shoulders, wings, tail, and the whole of the under plumage black, going off in the middle of the back to grayish; scapulars, rump, and upper tail-coverts white; there is a large patch of ochreous yellow on the nape and back of the neck; bill bluish-black, which in the female, young male, and adult male in his autumnal dress, is pale flesh-colour; the feathers of the tail are sharp at the end like a woodpecker's; legs brown.

The female, whose plumage the adult male assumes after the breeding season, has the back streaked with brownish-black, not unlike that of a lark, according to Catesby, and the whole under parts of a dirty yellow. The young males resemble the females.

BODENITE, an ore of Cerium resembling *Orthite*. It is found at Boden in Saxony.

BŒHMERIA, a genus of plants belonging to the natural order *Urticaceæ*. The species were formerly comprehended under the genus *Urtica*. One of the species *B. nivea*, formerly *Urtica nivea*, is the Rheea of Asam, and yields fibres of remarkable fineness and tenacity. It appears from the investigations of Dr. Falconer, that the plant which yields the celebrated grass-cloth of China is identical with the Asam plant. Several specimens of these fibres manufactured into light articles of dress were exhibited in the Indian collection at the Great Exhibition of 1851. The *B. nivea* is a herbaceous plant, with broad ovate leaves which are downy and white beneath, hence its specific name. It bears no sting.

BOERHAAVIA, a genus of plants named after the celebrated Boerhaave, belonging to the natural order *Nyctaginaceæ*. The species of *Boerhaavia* have generally emetic and purgative properties, and have been employed medicinally both by the natives of Peru and the East Indies, where the species grow. *B. tuberosa* is stated by Lindley to be the Yerba de la Purgacion of Peru, and that it is employed as a culinary vegetable. The root of *B. decumbens* is called Hog-Meat in Jamaica, and on account of its emetic properties it is sometimes called Ipecacuanha in Guyana. Sir Robert Schomburgh states that it is astringent, and is useful in dysentery. *B. decumbens* and *B. hirsuta* are also said to possess medicinal properties. (Lindley, *Vegetable Kingdom.*)

BOG. The name of Bog has been given indiscriminately to very different kinds of substances. In all cases the expression signifies an earthy substance wanting in firmness or consistency, which state seems to arise generally (perhaps not always) from the presence of a superabundant supply of moisture having no natural outlet or drain.

In some cases, where springs of water, or the drainage from an extensive area, are pent up near the surface of the soil, they simply render it soft or boggy, and in this state the land is perhaps more properly called a Quagmire. A second state of bog is where, in addition to the condition just described, a formation of vegetable matter is induced, which dying and being reproduced on the surface assumes the state of a spongy mass of sufficient consistence to bear a considerable weight. Bogs of this description are numerous and extensive in Ireland, where they are valuable from the use made of the solid vegetable matter, both as fuel and as a principal ingredient in composts for manures. Where the turf has been cut away for these purposes, several bogs have been reclaimed by draining; and the subsoil is then readily brought into cultivation. Bogs also occur in all parts of Great Britain where the form of the surface and the nature of the earth favour the general condition under which bog is formed. Thus there are bogs on the high granitic plateau of Cornwall, on the road from Launceston to Bodmin; and in the large granitic mass, of which Brown Willy is the centre, the bottoms of the valleys are covered with bogs, the lower part of which is consolidated into peat. Although peat-moss always springs from some moist spot, it will grow and spread over sound ground, and if not stopped by some natural or artificial impediment, such as a wall, would overrun whole districts. In this case it absorbs any moisture which reaches it, and retains it like a sponge.

The depth of a bog depends on the level of the surrounding grounds. It cannot rise much higher than the lowest outlet for the water. Where there is no immediate outlet the bog increases, until the evaporation is equal to the supply of the springs and rains, or till it rises to a level with its lowest boundary, where it becomes the source of a stream or river, and forms a lake. The mud being deposited at the bottom, gradually becomes a true peat, or is quite reduced to its elementary earths. In this case it may become a stratum of rich alluvial soil, which some convulsion of nature may lay dry for the benefit of future ages. From this circumstance has arisen the great advantage of draining bogs, to which the attention of agriculturists and men of science has often been profitably directed.

The bogs of Ireland are estimated in the whole to exceed in extent 2,800,000 English acres. The greater part of these bogs may be considered as forming one connected mass. If a line were drawn from Wicklow-Head on the east coast to Galway, and another line from Howth-Head, also on the east coast, to Sligo, the space included between those lines, which would occupy about one-fourth part of the entire superficial extent of Ireland, would contain about six-sevenths of the bogs in the island, exclusive of mere mountain-bogs, and bogs of no greater extent than 800 English acres. This district resembles in form a broad belt drawn from east to west across the centre of Ireland, having its narrowest end nearest to Dublin, and gradually extending its breadth as it approaches the western ocean. This great division is traversed by the river Shannon from north to south, which thus divides the great system of bogs into two parts. Of these, the division to the west of the river contains more than double the extent of bogs in the eastern division, so that if we suppose the whole of the bogs of Ireland (exclusive of mere mountain-bogs, and of bogs of less extent than 800 acres) to be divided into twenty parts, twelve of these parts will be found in the western division, and five parts in the eastern division of the district already described, while of the remaining three parts, two are to the south and one to the north of that district.

The smaller bogs, excluded from the foregoing computation, are very numerous in some parts. In the single county of Cavan there are above 90 bogs, not one of which exceeds 800 English acres, but which collectively contain about 17,600 English acres, without taking into the account many bogs the extent of which is from five to twenty acres each.

Most of the bogs which lie to the eastward of the Shannon and which occupy a considerable portion of the King's County and the county of Kildare, are generally known by the name of the Bog of Allen. It must not however be supposed that this name is applied to any one great morass; on the contrary, the bogs to which it is applied are perfectly distinct from each other, often separated by high ridges of dry country, and inclining towards different rivers as their natural directions for drainage.

The surface of the land rises very quickly from the Bog of Allen on all sides, particularly to the north-west, where it is composed to a considerable depth of limestone gravel, forming very abrupt hills. In places where the face of the hills has been opened the mass is found to be composed of rounded limestone, varying in size from two feet in diameter to less than one inch; the largest pieces are not so much rounded as the small, and frequently their sharp angles are merely rubbed off. They are usually penetrated by contemporaneous veins of Lydian stone, varying in colour from black to light gray. The colour of the limestone is usually light smoke-gray, rarely bluish-black; when it is bluish-black the fracture is large conchoidal; that of the gray is uneven, approaching to earthy. The Lydian stone when unattached to the limestone has usually a tendency to a rhomboidal form, sometimes cubical; the edges are more or less rounded; the longitudinal fracture is even, the cross fracture is conchoidal.

The Grand Canal from Dublin to Shannon Harbour passes through a considerable part of the great bog-district of Ireland. In forming this canal it was necessary to make considerable embankments, the surface-water of the canal being generally on a higher level than the surface of the immediately adjoining bogs. Where this was not the case advantage was taken of the circumstance to conduct the drainage of the bogs into trenches for the supply of the canal.

The bogs situated to the south of the great belt in the centre of Ireland occur in Tipperary, Kilkenny, Clare, and Queen's County; those to the north of that belt occur in Antrim, Down, Armagh, Tyrone, and Londonderry.

It appeared from the examination of the surveyors appointed by parliament in 1810 to investigate the nature and extent of the bogs in Ireland, that they consist of "a mass of the peculiar substance called peat, of the average thickness of twenty-five feet, nowhere less than twelve nor found to exceed forty-two—this substance varying materially in its appearances and properties in proportion to the depth at which it lies. The upper surface is covered with moss of various species, and to the depth of about ten feet is composed of a mass of the fibres of similar vegetables in different stages of decomposition, proportioned to their depth from the surface, generally however too open in their texture to be applied to the purposes of fuel; below this generally lies a light blackish-brown turf, containing the fibres of moss, still visible though not perfect, and extending to a further depth of perhaps ten feet under this. At a greater depth the fibres of vegetable matter cease to be visible, the colour of the turf becomes blacker and the substance much more compact, its properties as fuel more valuable, and gradually increasing in the degree of blackness and compactness proportionate to its depth; near the bottom of the bog it forms a black mass, which when dry has a strong resemblance to pitch or bituminous coal, having a conchoidal fracture in every direction, with a black shining lustre, and susceptible of receiving a considerable polish."

The surface of Irish bogs is not in general level; indeed it is most commonly uneven, sometimes swelling into hills and divided by valleys, thus affording great facilities for drainage. None of the bogs of Ireland which have been described occur on low ground, a fact which seemed to strengthen the opinion of their having always originated from the decay of forests. This theory of the original formation of bogs was at one time very generally adopted, but the result of more recent investigations shows that it cannot be supported. That some bogs may have been formed in this manner is not denied. It is stated in the 'Philosophical Transactions,' No. 275, that "the Romans under Ostorius, having slain many Britons, drove the rest into the forest of Hatfield (in Yorkshire), which at that time overspread all the low country; and the conqueror taking advantage of a strong south-west wind, set fire to the pitch-trees of which the forest was chiefly composed, and when the greater part of the trees were thus destroyed, the Roman soldiers and captive Britons cut down the remainder, except a few large ones, which were left growing as remembrancers of the destruction of the rest. These single trees did not long withstand the action of the winds, but falling into the rivers intercepted their currents, and caused the waters to rise and flood the whole flat country; hence the origin of the mosses and moory bogs which were afterwards formed there." This moorland near Hatfield, seven miles north-east from Doncaster, and about Thorne, is now a boggy peat covered with heath, several feet higher than the adjoining land, and very wet; whence it has been aptly compared to a sponge full of water. The Thorne waste with some adjacent tracts and the Hatfield Moor contain about 12,000 acres.

Underneath the peat in many places the layers of trees are found which serve to confirm this theory of the origin of these bogs. Some of them give indications of having been felled by human agency.

In the 'Ordnance Survey of the County of Londonderry,' presented by Lord Mulgrave to the British Association during its meeting (Aug. 1835) in Dublin, are some remarks on the subject which are deserving of attention:—

"In the production of bog, *Sphagnum* [*Sphagnum palustre*] is allowed on all hands to have been a principal agent, and superabundant moisture the inducing cause. To account for such moisture various opinions have been advanced, more especially that of the destruction of large forests, which by obstructing in their fall the usual channels of drainage, were supposed to have caused an accumulation of water. That opinion however cannot be supported; for as Mr. Aher remarks in the 'Bog Reports,' such trees as are found have generally six or seven feet of compact peat under their roots, which are found standing as they grew, evidently proving the formation of peat to have been previous to the growth of the trees, a fact which in relation to firs may be verified in probably every bog in this parish, turf from three to five feet thick underlying the lowest layer of such trees. This fact is indeed so strongly marked in the bog which on the Donegal side bounds the road to Muff, that the turf-cutters having arrived at the last depth of turf, find timber no longer, though formerly it was abundant, as is proved by their own testimony, from experience, and by the few scattered stumps which still remain resting on the present surface. Not so however with oaks, as their stumps are commonly found resting on the gravel at the base, or on the sides of the small hillocks of gravel and sand which so often stud the surfaces of bogs, and have by Mr. Aher been aptly called islands. He further adds that in the counties of Tipperary, Kilkenny, &c. they are popularly called Derries (signifying 'a place of oaks'), a name deserving attention whether viewed as expressive of the existing fact or as resulting from a lingering traditionary remembrance of their former condition, when, crowned with oaks, they were distinguishable from the dense forest of firs skirting the marshy plains around them. The strong resemblance to ancient water-courses of the valleys and basins which now contain bogs, and the occurrence of marl and shells at the bottoms of many, naturally suggest the idea of shallow lakes, a view of the subject adopted in the 'Bog Reports' by Messrs. Nimmo and Griffiths. Such lakes may have originated in the natural inequalities of the ground, or been formed by the choking up of channels of drainage by heaps of clay and gravel, or they may have been reduced to the necessary state of shallowness by the gradual wearing away of obstacles which had dammed up and retained their waters at a higher level."

The probable process of the formation of bog in such cases is thus explained in the 'Ordnance Survey:'—"A shallow pool induced and favoured the vegetation of aquatic plants, which gradually crept in from the borders towards the deeper centre. Mud accumulated round their root and stalks, and a spongy semi-fluid mass was thus formed, well fitted for the growth of moss, which now, especially *Sphagnum*, began to luxuriate. This, absorbing a large quantity of water and continuing to shoot out new plants above while the old were decaying, rotting, and compressing into a solid substance below, gradually replaced the water by a mass of vegetable matter. In this manner the marsh might be filled up, while the central or moister portion continuing to excite a more rapid growth of the moss, it would be gradually raised above the edges until the whole surface had attained an elevation sufficient to discharge the surface-water by existing channels of drainage, and calculated by its slope to facilitate their passage, when a limit would be in some degree set to its further increase."

According to the personal observations of Mr. Griffiths, made during many years, the growth of turf in these bogs is very rapid, amounting sometimes to two inches in depth in one year: this however is stated to be an excessive growth under peculiarly favourable circumstances.

The roots which were attached to the ground decay, and the whole of the surface becomes a floating mass of long interlaced fibres which when taken out has been significantly called in Ireland 'Old Wives' Tow.' The black mass of the bog is a mud almost entirely formed of decomposed vegetable fibres, but not of sufficient specific gravity to sink to the bottom; thus producing that semi-liquid state which distinguishes a quaking bog from a peat-moss. The vegetation which continues on the surface and at some depth below has the appearance of a fine green turf. In many cases the roots are so matted together and so strong as to form a web capable of bearing the gentle and light tread of a man accustomed to walk over bogs, bending and waving under him without breaking; and while a person unskilfully attempting to walk upon it would infallibly break through and be plunged in the bog like a venturous skater on unsound ice, the practised 'bog-trotter' with proper precautions passes over them in safety. This has often been of considerable advantage in war or in the pursuit of illegal employments. The fugitive escapes over his native bogs where the pursuer cannot venture to follow, or if he does he generally pays the penalty of his ignorance or rashness by sinking in them. Many examples of this were witnessed in Ireland during the last rebellion, and many bodies have been found in bogs years after, preserved from decay and tanned in a manner by the astringent principle which is always found where vegetable fibre has been decomposed under water.

When bogs become consolidated or compressed they are called Peat-Mosses. The consolidation here mentioned must be carried to a considerable extent before the soil is capable of sustaining such a growth of timber as it is seen to have frequently borne.

An extensive tract of peat-moss (Chat-Moss) in the county of Lancaster attracted public attention some years ago, from the circumstance of the Liverpool and Manchester railway having been carried through it. The length of Chat-Moss is about 6 miles, its greatest breadth about 3 miles, and its depth varies from 10 to upwards of 30 feet, the whole of which is pure vegetable matter throughout, without the slightest mixture of sand, gravel, or other material. On the surface it is light and fibrous, but it becomes more dense below. At a considerable depth it is found to be black, compact, and heavy, and in some respects resembles coal: it is in fact exactly similar to the composition of the bogs of Ireland, as already described.

The Moss is bounded on all sides by ridges of rolled stones mixed with clay, which prevent the immediate discharge of its waters. It is probable that this bar, by interrupting the course of the waters, originally caused the growth of Chat-Moss. This moss presents at its edges nearly an upright face; the spongy surface of the moss being elevated at a very short distance from the edge from 10 to 20 feet above the level of the immediately adjoining land. The immediate substratum to the bog is a bed of silicious sand, which varies from one to five feet in thickness, below which is a bed of bluish and sometimes reddish clay marl of excellent quality. This marl varies in thickness very considerably; in some parts it is not more than three feet, in others its depth has not been ascertained; below the marl is a bed of sandstone-gravel of unknown thickness. It is this bed of gravel which extends beyond the edge of the bog, and prevents the direct discharge of the waters from the flat country to the north into the river Irwell. (See Camden's remarks on this Moss, in his 'Britannia,' vol. ii. p. 966, Gibson's edition.)

About 1797 the late Mr. Roscoe of Liverpool began to improve Trafford-Moss, a tract of 300 acres, lying 2 miles east of Chat-Moss, which operation was so successful as to encourage him to proceed with the improvement of Chat-Moss, the most extensive lowland bog in England, including 7000 acres. After making a great variety of experiments Mr. Roscoe gave it as his decided opinion "that the best method of improving moss-land is that of the application of a calcareous substance, in sufficient quantity to convert the moss into a soil, and by the occasional use of animal or other extraneous manures, such as the course of cultivation and the nature of the crops may be found to require."

In June 1833 an ancient wooden house was discovered in Drumkelin Bog, in the county of Donegal in Ireland. The framework of the house was very firmly put together, without any iron; the roof was flat and made of thick oak planks. The house was 12 feet square and 9 feet high: it consisted of two floors one above the other, each about 4 feet high; one side of the house was entirely open. The whole stood on a thick layer of sand spread on the bog, which continues to the depth of 15 feet below the foundation of the house. On the same level as the foundation of the house stumps of oak trees were found standing, just such as had supplied the timber of the house; and beneath all this there are still 15 feet of peat.

Bogs not unfrequently burst out and suddenly cover large tracts. This phenomenon happened in 1835 in Ireland, on a part of Lord O'Neill's estate, on the Ballymena road, in the neighbourhood of Randalstown. On the 19th September an individual near the ground was surprised by hearing a rumbling noise as if under the earth, and immediately after a portion of the bog moved forward a few perches, when it exhibited a broken rugged appearance, with a soft peaty substance boiling up through the chinks. It remained in this state until the 22nd, when it again moved suddenly forward, covering corn-fields, potato-fields, turf-stacks, hay-ricks, &c. The noise made by its burst was so loud as to alarm the inhabitants adjoining, who on perceiving the flow of the bog immediately fled. It directed its course towards the river Maine which lay below it; and so great was its force that the moving mass was carried a considerable way across the river. Owing to the heavy rain which had fallen for some time previously, the river forced its channel through the matter deposited in its bed, and considerable damage was thus obviated which would otherwise have occurred from the forcing back of the waters.

The Irish Amelioration Society, the British and Irish Peat Company, and other associations, have of late years been engaged in converting turf and peat into charcoal and other products. Charcoal from turf and peat to a considerable amount has already been made in Ireland. There are two methods of carbonising the turf or peat, either to subject it to heat in close vessels, by which the other products are saved as well as the carbon, or to pile it in heaps and apply heat, in the same manner as for wood-charcoal. The heating in close vessels is expensive, and there is not sufficient compensation in the distilled products. The acetic acid and the tar are generally small in quantity and the gases are deficient in illuminating power: hence the charcoal is the only product of much value. The charcoal obtained is from 30 to 40 per cent. of the weight of the dry turf. The more economical mode of piling up the turf in heaps has hitherto been found preferable. The sods are regularly arranged, and laid as close as possible; they are better for being large, say 15 inches long, 6 inches broad, and 5 inches deep. The heaps are built hemispherically, and are smaller than those of wood. The mass is allowed to heat more than is necessary for wood, and the process is very carefully attended to, on account of the great combustibility of the material. The quantity of charcoal obtained by this method is from 25 to 30 per cent. of the weight of dry turf. The charcoal so obtained is very light and very inflammable, and possesses nearly the volume of the turf. It usually burns with a slight flame, as the volatile matters are not entirely expelled.

A specimen subjected to analysis gave the following result: —

Carbon	89·90
Hydrogen	1·70
Oxygen and Nitrogen	4·20
Ashes	4·20
	100·00

For many industrial purposes charcoal so prepared is too light, but compressed turf converted into charcoal may attain a density far superior to wood-charcoal, and even equal to that of the best coke obtained from coal.

It is of peculiar importance in the preparation of charcoal from turf that the material selected should be as free as possible from impurities. Surface-turf generally contains less than 10 per cent. of ash, whilst that of the dense turf of the lower strata sometimes contains from 20 to 30 per cent., a quantity which renders it unfit for most practical purposes.

BOG-IRON-ORE, a loose earthy ore of iron, consisting of Peroxide of Iron and water. It is of a brownish-black colour, and occurs in low boggy grounds.

BOG-MANGANESE, a native hydrated Peroxide of Manganese; also called *Wad*.

BOGMARUS, a genus of Fishes, to which the Vaagmaer, or Deal-Fish is referred by Schneider under the specific title of *B. Islandicus*. [TRACHYPTERUS.]

BOG-MYRTLE. [MYRICA.]

BOHEMIAN CHATTERER. [BOMBYCILLA.]

BOHEMIAN WAX-WING. [BOMBYCILLA.]

BOIDÆ, the fourth family of the second order (*Ophidia*) of Reptiles. This family is known by the following technical characters:—The ventral shields narrow (except in *Bolyeria*), transverse, band-like, often six-sided; the hinder limbs developed under the skin, formed of several bones and ending in an exserted horny spine, placed one on each side of the vent; the tail short, generally prehensile; the pupil oblong, erect (except in *Tortrix*).

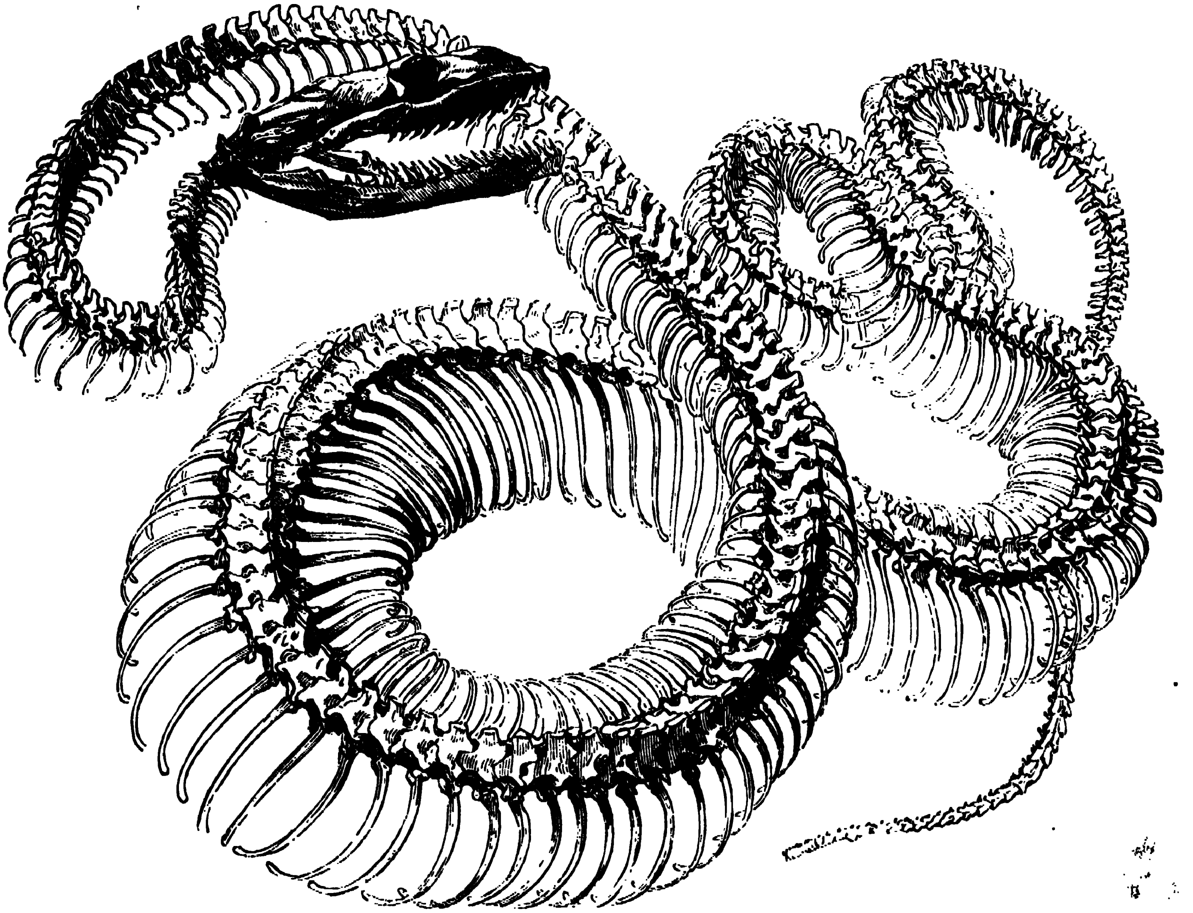
The species live in marshy places. Fixing themselves by the tail to some aquatic tree, they allow themselves to float, and thus entrap their prey. They are without venom, the absence of which is amply compensated by immense muscular power, enabling some of the species to kill large animals by constriction, preparatory to swallowing them whole.

There are few fables which have not some truth for their origin. The voyages of Sinbad have become proverbial; but the stories of the monstrous serpents in the valley of diamonds, and of the "serpent of surprising length and thickness, whose scales made a rustling as he wound himself along," that swallowed up two of his companions, probably had their foundation in traditions of the size and strength of a family of serpents belonging to the Old World, but nearly allied in their organisation and habits to those which we are about to consider.

Of the same race probably were the monsters to which the following allusions are made by ancient writers:—

Aristotle (book viii. c. 28) writes of Libyan serpents of enormous size, and relates that certain voyagers to that coast were pursued by some of them so large that they overset one of the triremes. The two monstrous snakes sent by Juno to strangle the infant Hercules in his cradle, described by Theocritus in his 24th Idyll, exhibit some of the peculiarities of these reptiles. The way in which Theocritus represents them to have rolled their folds around the boy, and relaxed them when dying in his grasp, indicates the habit of a constricting serpent. Virgil's Laocoon, and the unrivalled marble group, which the poet's description most probably called into existence, owe their origin undoubtedly to the stories current of constricting serpents. Valerius Maximus (book i. c. 8, s. 19), quoting Livy, gives a relation of the alarm into which the Romans under Regulus were thrown by an enormous snake, which had its lair on the banks of the Bagradas or Magradas (Mejerda), near Utica. It is said to have swallowed many of the soldiers, to have killed others in its folds, and to have kept the army from the river; till at length, being invulnerable by ordinary weapons, it was destroyed by heavy stones slung from the military engines used in sieges. But according to the historian its persecution of the army did not cease with its death; for the waters were polluted with its gore, and the air with the steams from its corrupted carcass, to such a degree that the Romans were obliged to move their camp, taking with them however the skin, 120 feet in length, which was sent to Rome. Gellius, Orosius, Florus, Silius Italicus, and Zonaras, make mention of the same serpent nearly to the same effect. Pliny (viii. 14, 'De Serpentibus Maximis et Bois') says that Megasthenes writes that serpents grow to such a size in India that they swallowed entire stags and bulls. (See also Nearchus, quoted by Arrian, 'Indic.' 15.) He speaks too of the Bagradian serpent above mentioned as matter of notoriety, observing that it was 120 feet long, and that its skin and jaws were preserved in a temple at Rome till the time of the Numantine war: and he adds, that the serpents called *Boæ* in Italy confirm this, for that they grow to such a size that in the belly of one killed on the Vatican Hill in the reign of Claudius an entire infant was found. Suetonius (in 'Octav.' 43) mentions the exhibition of a serpent 50 cubits in length in front of the comitium. But without multiplying instances from Ælian and others, we will now come to more modern accounts. Bontius (v. 23) says, "The Indian serpents are so multitudinous that my paper would fail me before I enumerated them all; nevertheless I must say something about the great ones, which sometimes exceed 36 feet in length, and are of such capacity of throat and stomach that they swallow entire boars." He then speaks of the great power of distention in the jaws, adding, "To confirm this there are those alive who partook with General Peter Both of a recently swallowed hog, cut out of the belly of a serpent of this kind. They are not venomous, but they strangle by powerfully applying their folds around the body of a man or other animal." Mr. M'Leod, in his interesting 'Voyage of H. M. S. Alceste,' p. 312, gives the following account:—

"It may here be mentioned that during a captivity of some months at Whidah, in the kingdom of Dahomey, on the coast of Africa, the author of this narrative had opportunities of observing snakes more than double the size of this one just described; but he cannot venture to say whether or not they were of the same species, though he has no doubt of their being of the genus *Boa*. They killed their prey however precisely in a similar manner, and from their superior bulk were capable of swallowing animals much larger than goats or sheep. Governor Abson, who had for 37 years resided at Fort William (one of the African Company's settlements there), described some desperate struggles which he had either seen, or had come to his knowledge, between the snakes and wild beasts as well as the smaller cattle, in which the former were always victorious. A negro herdsman belonging to Mr. Abson (who afterwards limped for many years about the fort) had been seized by one of these monsters by the thigh, but from his situation in a wood the serpent, in attempting to throw himself around him, got entangled with a tree; and the man being thus preserved from a state of compression which would instantly have rendered him quite powerless, had presence of mind enough to cut with a large knife which he carried about with him deep gashes in the neck and throat of his antagonist, thereby killing him, and disengaging himself from his frightful situation. He never afterwards however recovered the use of that limb, which had sustained considerable injury from his fangs and the mere force of his jaws." All these gigantic serpents were most probably the Pythons of modern nomenclature.



Skeleton of *Boa Constrictor*.

According to Pliny the name *Boa* was given to these serpents because they were said to be at first nourished by the milk of cows, and Johnston and others observe that they derived the name not so much from their power of swallowing oxen as from a story current in old times of their following the herds and sucking their udders. Boa is also stated by some to be the Brazilian name for a serpent.

Before entering upon the subdivisions of this family we will examine some of the most remarkable points in the structure and organisation of the *Boidæ*.

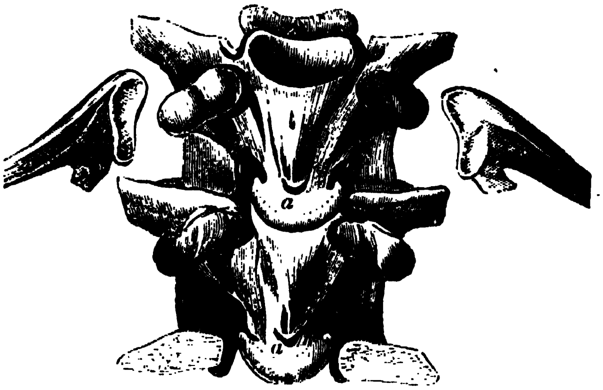
On looking at the accompanying representation of the skeleton of a *Boa Constrictor*, drawn from the beautiful preparation in the British Museum, we first observe the strong close-set teeth, of which there is a double row on each side of the upper jaw, all pointing backwards, and giving the serpent the firmest hold of its struggling victim, which is thus deprived of the power of withdrawing itself when once locked within the deadly jaws. Serpents do not masticate. The prey is swallowed whole, and to assist deglutition their under jaw consists of two bones easily separable at the symphysis, or point of junction, while the bone similar to the os quadratum in birds, by the intervention of which it is fitted to the cranium, further facilitates the act. The upper jaw moreover is so constructed as to admit of considerable motion.

We next observe the spine, formed for the most extensive mobility, and the multitude of ribs constructed as organs of rapid progression, when joined to the belly-scales, or scuta, with which the whole inferior surface of the body may be said to be shod. "When the snake," writes Sir Everard Home, "begins to put itself in motion, the ribs of the opposite sides are drawn apart from each other, and the small cartilages at the end of them are bent upon the upper surfaces of the abdominal scuta on which the ends of the ribs rest, and as the ribs move in pairs the scutum under each pair is carried along with it. This scutum by its posterior edge lays hold of the ground, and becomes a fixed point from whence to set out anew. This motion is beautifully seen when a snake is climbing over an angle to get upon a flat surface. When the animal is moving it alters its shape from a circular or oval form to something approaching to a triangle, of which the surface on the ground forms the base. The coluber and boa having large abdominal scuta, which may be considered as hoofs or shoes, are the best fitted for this kind of progressive motion." ('Lectures on Comparative Anatomy,' vol. i.)

Sir Everard, in the same lecture, speaking of the ribs as organs of locomotion, says:—"An observation of Sir Joseph Banks during the exhibition of a coluber of unusual size first led to this discovery. While it was moving briskly along the carpet he said he thought he saw the ribs come forward in succession like the feet of a caterpillar. This remark led me to examine the animal's motion with more accuracy, and on putting the hand under its belly while the snake was in the act of passing over the palm the ends of the ribs were distinctly felt pressing upon the surface in regular succession, so as to leave no doubt of the ribs forming so many pairs of levers by which the animal moves its body from place to place." The merit however of this discovery is due to the sharp-sighted Tyson, who was the first to observe the locomotive power of the ribs of the *Boa*.

Sir Everard Home informs us by what additional mechanism this faculty is effected. The ribs, he observes, are not articulated in snakes between the vertebræ, but each vertebra has a rib attached to it by two slightly concave surfaces that move upon a convex protuberance on the side of the vertebra, by which means the extent of motion is unusually great; and the lower end of each vertebra having a globular form fitted to a concavity in the upper end of the vertebra below it, they move readily on one another in all directions. The muscles which bring the ribs forward, according to Sir Everard, consist of five sets—one from the transverse process of each vertebra to the rib immediately behind it, which rib is attached to the next vertebra. The next set goes from the rib a little way from the spine, just beyond where the former terminates; it passes over two ribs, sending a slip to each, and is inserted into the third: there is a slip also connecting it with the next muscle in succession. Under this is the third set, which arises from the posterior side of each rib, passes over two ribs, sending a lateral slip to the next muscle, and is inserted into the third rib behind it. The fourth set passes from one rib over the next, and is inserted into the second rib. The fifth set goes from rib to rib. On the inside of the chest there is a strong set of muscles attached to the anterior surface of each vertebra, and passing obliquely forwards over four ribs to be inserted into the fifth, nearly at the middle part between the two extremities. From this part of each rib a strong flat muscle comes forward on each side before the viscera, forming the abdominal muscles, and uniting in a beautiful middle tendon, so that the lower half of each rib which is beyond the origin of this muscle, and which is only laterally connected to it by loose cellular membrane, is external to the belly of the animal, and is used for the purpose of progressive motion; while that half of each rib next the spine, as far as the lungs extend, is employed in respiration. At the termination of each rib is a small cartilage in shape corresponding to the rib, only tapering to the point. Those of the opposite ribs have no connection, and when the ribs are drawn outwards by the muscles, they are separated to some distance, and rest through their whole length on the inner surface of the abdominal scuta, to which they are connected by a set of short muscles; they have also a connection with the cartilages of the neighbouring ribs by a set of short straight muscles. These observations apply to snakes in general, but the muscles have been examined in a *Boa Constrictor* 3 feet 9 inches long preserved in the Hunterian Museum. In all snakes, adds the author, the ribs are continued to the anus, but the lungs seldom occupy more than one half of the extent of the cavity covered by the ribs. Consequently these lower ribs can only be employed for the purpose of progressive motion, and therefore correspond in that respect with the ribs in the *Draco volans* superadded to form the wings.

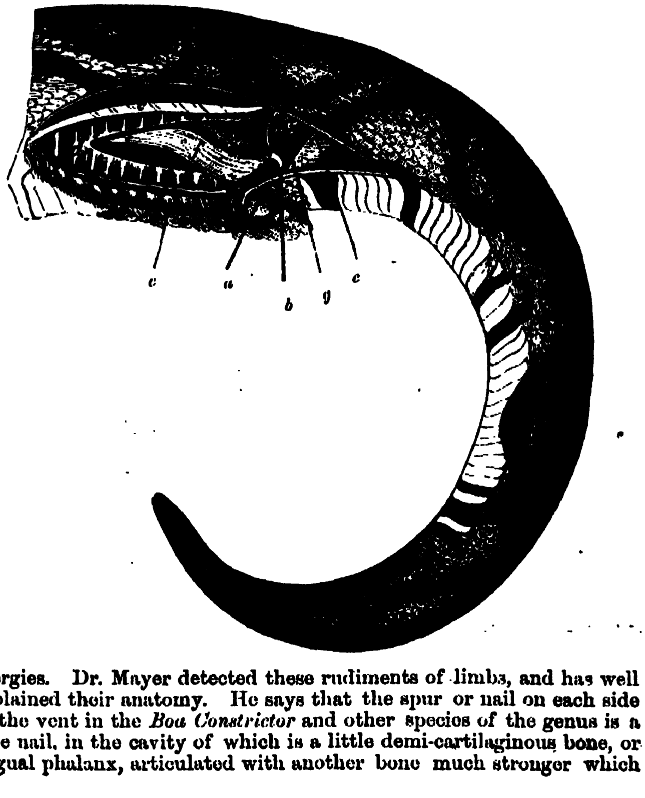
The subjoined cut, copied from that given as an illustration by Sir Everard Home, will explain the articulating surfaces of the vertebræ and ribs; and on the under surface of the former will be seen the protuberance for the attachment of the muscles which are employed in crushing the animals round which the snake entwines itself.



The cut exhibits two vertebræ, and portions of two ribs of a so-called *Boa Constrictor*, drawn from a skeleton sent from the East Indies by the late Sir William Jones, and deposited in the Hunterian Museum. The letters, *a*, *a*, point to the protuberance on the under surface for the attachment of the constricting muscles, according to Sir Everard Home.

Though the term *Boa Constrictor* is used throughout by Sir Everard Home in his lecture, there can be little doubt that the serpent sent from India by Sir William Jones was a Python. The small specimen from which the description of the organs employed in progressive motion was taken may have been a boa. But whether boa or python, it would have had the hooks or spurs near the vent, and the bones and muscles belonging to these spurs, which are of no small consequence in the organisation of a boa or a python, rudiments of limbs though they be; these appear to have escaped Sir Everard Home's observation, occupied as he was in following out the mechanism of progressive motion.

No one can read of the habits of these reptiles in a state of nature without perceiving the advantage which they gain when holding on by their tails on a tree, their heads and bodies in ambush, and half floating on some sedgy river, they surprise the thirsty animal that seeks the stream. These hooks help the serpent to maintain a fixed point; they become a fulcrum which gives a double power to his energies. Dr. Mayer detected these rudiments of limbs, and has well explained their anatomy. He says that the spur or nail on each side of the vent in the *Boa Constrictor* and other species of the genus is a true nail, in the cavity of which is a little demi-cartilaginous bone, or ungual phalanx, articulated with another bone much stronger which



is concealed under the skin. This second bone of the rudiment of a foot in the *Boa* has an external thick condyle, with which the ungual phalanx is articulated, as above stated; it presents, besides a smaller internal apophysis, which places it in connection with the other bones of the skeleton. These bones are the appendages of a tibia, or leg-bone, the form and relative position of which will be understood by a reference to the subjoined cuts, copied from Dr. Mayer's 'Memoir.' ('Trans. Soc. Nat. Curios.,' translated in 'Annales des Sciences' for 1826.)

The previous figure represents the tail of a *Boa Constrictor; a*, the vent; *b*, the hook or spur of the left side; *c*, the subcutaneous muscle; *d*, ribs and intercostal muscles; *e*, transverse muscle of the abdomen; *f*, bone of the leg enveloped in its muscles; *g*, abductor muscle of the foot; *h*, adductor muscle of the foot. The arrangement of the scuta, or shields, of one entire piece under the tail, characteristic of the true Boas, will be here observed. In the Pythons the shields beneath the tail are ranged in pairs.

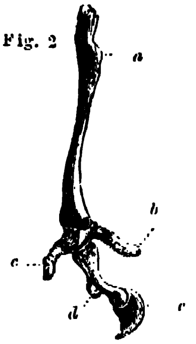


Fig. 2

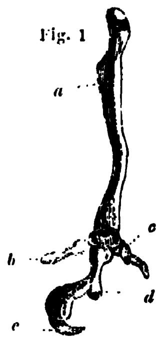

Fig. 1

We here have a representation of the osteology of this rudimentary limb, taken from the same author. *Fig.* 1 represents the left posterior limb of the *Boa Scytale*, seen anteriorly: *a*, tibia, or leg-bone; *b*, external bone of the tarsus; *c*, internal bone of the tarsus; *d*, bone of the metatarsus with its apophysis; *e*, nail or hook.

Fig. 2 represents the same limb, seen posteriorly.

Doctors Hopkinson and Pancoast have given in the 'Transactions of the American Philosophical Society,' held at Philadelphia, for promoting useful knowledge (vol. v. new series, part i.), an interesting account of the visceral anatomy of the Python (Cuvier), described by Daudin as the *Boa reticulata*. And here it may be as well to remark that the differences between the Boas and the Pythons are so small, that the accounts given of the constricting powers and even of the principal anatomical details of the one, may be taken as illustrative of the same points in the history of the other.

Perhaps the best way of illustrating the habits of these creatures in seizing and killing their prey is to relate some of the incidents with which books of travels abound.

Mr. M'Leod, in his 'Voyage of H.M.S. Alceste,' gives the following painfully vivid account of a serpent, a native of Borneo, 16 feet long, and of about 18 inches in circumference, which was on board. There were originally two; but one, to use Mr. M'Leod's expression, "sprawled overboard and was drowned."

"During his stay at Ryswick," says Mr. M'Leod, speaking of the survivor, "he is said to have been usually entertained with a goat for dinner, once in every three or four weeks, with occasionally a duck or a fowl by way of a dessert. The live-stock for his use during the passage, consisting of six goats of the ordinary size, were sent with him on board, five being considered as a fair allowance for as many months.

"At an early period of the voyage we had an exhibition of his talent in the way of eating, which was publicly performed on the quarter-deck, upon which his crib stood. The sliding part being opened, one of the goats was thrust in, and the door of the cage was shut. The poor goat, as if instantly aware of all the horrors of its perilous situation, immediately began to utter the most piercing and distressing cries, butting instinctively at the same time, with its head towards the serpent, in self-defence.

"The snake, which at first appeared scarcely to notice the poor animal, soon began to stir a little, and turning his head in the direction of the goat, he at length fixed a deadly and malignant eye on the trembling victim, whose agony and terror seemed to increase; for previous to the snake seizing his prey, it shook in every limb, but still continuing its unavailing show of attack, by butting at the serpent, which now became sufficiently animated to prepare for the banquet. The first operation was that of darting out his forked tongue, and at the same time rearing a little his head; then suddenly seizing the goat by the fore-leg with his fangs, and throwing it down, it was encircled in an instant in his horrid folds. So quick indeed and so instantaneous was the act, that it was impossible for the eye to follow the rapid convolution of his elongated body. It was not a regular screw-like turn that was formed, but resembling rather a knot, one part of the body overlaying the other, as if to add weight to the muscular pressure, the more effectually to crush the object. During this time he continued to grasp with his fangs, though it appeared an unnecessary precaution, that part of the animal which he had first seized. He then slowly and cautiously unfolded himself, till the goat fell dead from his monstrous embrace, when he began to prepare himself for swallowing it. Placing his mouth in front of the dead animal, he commenced by lubricating with his saliva that part of the goat, and then taking its muzzle into his mouth, which had, and indeed always has, the appearance of a raw lacerated wound, he sucked it in, as far as the horns would allow. These protuberances opposed some little difficulty, not so much from their extent as from their points; however they also in a very short time disappeared, that is to say, externally; but their progress was still to be traced very distinctly on the outside, threatening every moment to protrude through the skin. The victim had now descended as far as the shoulders; and it was an astonishing sight to observe the extraordinary action of the snake's muscles when stretched to such an unnatural extent—an extent which must have utterly destroyed all muscular power in any animal that was not like himself endowed with very peculiar faculties of expansion and action at the same time. When his head and neck had no other appearance than that of a serpent's skin stuffed almost to bursting, still the workings of the muscles were evident; and his power of suction, as it is erroneously called, unabated; it was in fact the effect of a contractile muscular power, assisted by two rows of strong hooked teeth. With all this he must be so formed as to be able to suspend for a time his respiration; for it is impossible to conceive that the process of breathing could be carried on while the mouth and throat were so completely stuffed and expanded by the body of the goat, and the lungs themselves (admitting the trachea to be ever so hard) compressed as they must have been by its passage downwards.

"The whole operation of completely gorging the goat occupied about two hours and twenty minutes, at the end of which time the tumefaction was confined to the middle part of the body, or stomach, the superior parts, which had been so much distended, having resumed their natural dimensions. He now coiled himself up again, and lay quietly in his usual torpid state for about three weeks or a month, when his last meal appearing to be completely digested and dissolved, he was presented with another goat, which he killed and devoured with equal facility. It would appear that almost all he swallows is converted into nutrition, for a small quantity of calcareous matter (and that perhaps not a tenth part of the bones of the animal), with occasionally some of the hairs, seemed to compose his general fæces. . . . .

"It was remarked, especially by the officers of the watch, who had better opportunities of noticing this circumstance, that the goats had always a great horror of the serpent, and evidently avoided that side of the deck on which his cage stood." (P. 305.)

Mr. Broderip, in the second volume of the 'Zoological Journal,' after referring to Mr. M'Leod's interesting narrative, of the correctness of which, as far as it goes, he says he has not a single doubt, and observing that two points in that description struck him forcibly, the one as being contrary to the probable structure of the animal, and the other as being contrary to Mr. Broderip's observations, proceeds to give the following account of the manner in which the serpent takes its prey in this country.

Mr. Broderip had an opportunity of seeing one of these creatures when kept in the Tower. The keeper says Mr. Broderip "sent to inform me that one of these reptiles had just cast his skin, at which period they, in common with other serpents, are most active and eager for prey. Accordingly I repaired with some friends to the Tower, where we found a spacious cage, the floor of which consisted of a tin case covered with red baize and filled with warm water, so as to produce a proper temperature. There was the snake, 'positis novus exuviis,' gracefully examining the height and extent of his prison as he raised, without any apparent effort, his towering head to the roof and upper parts of it, full of life, and brandishing his tongue.

"A large buck rabbit was introduced into the cage. The snake was down and motionless in a moment. There he lay like a log without one symptom of life, save that which glared in the small bright eye twinkling in his depressed head. The rabbit appeared to take no notice of him, but presently began to walk about the cage. The snake suddenly, but almost imperceptibly, turned his head according to the rabbit's movements, as if to keep the object within the range of his eye. At length the rabbit, totally unconscious of his situation, approached the ambushed head. The snake dashed at him like lightning. There was a blow—a scream—and instantly the victim was locked in the coils of the serpent. This was done almost too rapidly for the eye to follow: at one instant the snake was motionless; in the next he was one congeries of coils round his prey. He had seized the rabbit by the neck just under the ear, and was evidently exerting the strongest pressure round the thorax of the quadruped; thereby preventing the expansion of the chest, and at the same time depriving the anterior extremities of motion. The rabbit never cried after the first seizure; he lay with his hind legs stretched out, still breathing with difficulty, as could be seen by the motion of his flanks. Presently he made one desperate struggle with his hind legs; but the snake cautiously applied another coil with such dexterity as completely to manacle the lower extremities, and, in about eight minutes, the rabbit was quite dead. The snake then gradually and carefully uncoiled himself, and, finding that his victim moved not, opened his mouth, let go his hold, and placed his head opposite to the fore part of the rabbit. The boa generally, I have observed, begins with the head; but in this instance the serpent, having begun with the fore legs, was longer in gorging his prey than usual, and in consequence of the difficulty presented by the awkward position of the rabbit, the dilatation and secretion of lubricating mucus were excessive. The serpent first got the fore legs into his mouth; he then coiled himself round the rabbit, and appeared to draw out the dead body through his folds; he then began to dilate his jaws, and holding the rabbit firmly in a coil as a point of resistance, appeared to exercise at intervals the whole of his anterior muscles in protruding his stretched jaws and lubricated mouth and throat at first against and soon after gradually upon and over his prey. The curious mechanism in the jaws of serpents which enables them to swallow bodies so diproportioned to their apparent bulk is too well known to need description; but it may be as well to state that the symphysis of the under jaw was separated in this case, and in others which I have had an opportunity of observing. When the prey was completely ingulphed, the serpent lay for a few moments with his dislocated jaws still dropping with the mucus which had lubricated the parts, and at this time he looked quite sufficiently disgusting. He then stretched out his neck, and at the same moment the muscles seemed to push the prey further downwards. After a few efforts to replace the parts, the jaws appeared much the same as they did previous to the monstrous repast.

"I now proceed to the first of the two points above alluded to, and have to state my opinion that the *Boa Constrictor* does respire 'when his head and neck have no other appearance than that of a serpent's skin stuffed almost to bursting;' and I think that, upon a more close examination, the same phenomenon would have been observable in the serpent shipped at Batavia. It is to be regretted that the dissection of that serpent appears to have been confined to the stomach; at least nothing is said of any other part of the animal. I have never had an opportunity of dissecting the pulmonary system of a boa, or of satisfying myself as to the structure of the extremely long trachea, which must be very firm to resist such an immense pressure; but I believe, from a near and accurate inspection, in company with others, that respiration goes on during the period of the greatest dilatation. While these serpents are in the act of constringing or swallowing their prey, they appear to be so entirely pervaded by the *ὄρεξις* [appetito] which then governs them, that I am convinced they would suffer themselves to be cut in pieces before they would relinquish their victim. I have assisted in taking them up, and removing them with their prey in their coils, without their appearing to be in the least disturbed by the motion, excepting that, if after the victim is no more and the constriction is somewhat relaxed, an artificial motion be given to the dead body, they instantly renew the constriction. When thus employed they may be approached closely and with perfect security for the reason above stated, and I have uniformly found that the larynx is, during the operation of swallowing, protruded sometimes as much as a quarter of an inch beyond the edge of the dilated lower jaw. I have seen, in company with others, the valves of the glottis open and shut, and the dead rabbit's fur immediately before the aperture stirred, apparently by the serpent's breath, when his jaws and throat were stuffed and stretched to excess. In the case above mentioned, where the prey was taken very awkwardly, and the dilatation was consequently much greater than usual, I saw this wonderful adaptation of means to the exigencies of the animal much more clearly than I had ever seen it before.

"With regard to the next point, it is more difficult to account for the variance between the agony of antipathy shown by the goat as described by Mr. M'Leod, and the indifference which I have uniformly observed in the full grown fowls and rabbits presented to these serpents for prey. Immediately after our boa had swallowed his first rabbit, a second was introduced; but the serpent now exhibited a very different appearance. The left side of his lower jaw was hardly in its place, and he moved about the cage instead of lying in wait as on the former occasion. As for the rabbit, after he had been incarcerated a little while, he treated the snake with the utmost contempt, biting it when in his way, and moving it aside with his head. The snake, not having his tackle in order, for his jaw was not yet quite right, appeared anxious to avoid the rabbit, which at last stumbled upon the snake's head in his walks, and began to treat it so roughly, that the rabbit was withdrawn for fear of his injuring the snake. This treatment of the snake by the rabbit did not appear to be the effect of anger or hatred, but to be adopted merely as a mode of removing something, which he did not appear to understand, out of his way. I have seen many rabbits and fowls presented to different specimens of boa for prey, and I never saw the least symptom of uneasiness either in the birds or quadrupeds. They appear at first to take no notice of the serpent, large as it is, and when they do discover it they do not start, but seem to treat it with the greatest indifference. I remember one evening going up into the room where one of these snakes was kept at Exeter 'Change, and seeing the hen which was destined for the prey of the boa, very comfortably at roost upon the serpent. The keeper took the hen in his hands and held it opposite to the head of the snake, without succeeding in inducing him to take the bird, which, when let out of the keeper's hands again, settled herself down upon the serpent for the night.

"The only solution which I can offer of the difference between Mr. M'Leod's description and my experience, is one which I do not propose as absolutely satisfactory, but which may nevertheless be found to approach the truth. The goats put on board at Batavia for the serpent, which it appears was brought from Borneo, were in all probability natives of Java, and if so, they would, according to the wonderful instinct which nature has implanted in animals for their preservation, be likely to have a violent antipathy to large serpents, such as those which there lurk for their prey. The great Python is a native of Java, and if these goats were wild, or originally from the wild stock of the island, their instinctive horror at the sight of the destroyer may be thus accounted for. But our domestic fowls and rabbits (the stock of the latter most probably indigenous, and that of the former of such remote importation, and so much changed by descent, as to be almost on the same footing), having no such natural enemy as a large serpent, against which it is necessary for them to be on their guard, are entirely without this instinct, although it is strong enough in the case of their ordinary enemies, such as hawks, dogs, and cats; and they consequently view the boa which is about to dash at them with the same indifference as if he were a log of wood."

We now proceed to give an account of the genera and species of the family *Boidæ*, and in doing this we shall follow the arrangement of Dr. J. E. Gray in the Catalogue of the specimens of Snakes in the British Museum.

I. *Tail prehensile, strong; Head distinct; Muzzle truncated.*

a. Subcaudal plate two-rowed; intermaxillary or incisive teeth distinct; superciliary bone distinct.

* Crown of head with small shield-like plates.

1. *Morelia.* Upper and lower labial shields deeply pitted; muzzle with symmetrical shields. There are two species of this genus, one with the vertical plate indistinct, the other with the same plate distinct:—

M. spilotes (*Coluber argus*, Linnæus, *Coluber spilotes*, Lacépède), the Diamond-Snake. This species has the vertical plates indistinct. It is of a bluish-black colour, very irregularly yellow, spotted, a spot on the centre of each scale, forming a group of five or six together or a kind of tied blotch; occiput with an angular band. It is a native of Australia.

M. variegata, the Carpet-Snake. Vertical plates distinct. It is whitish, with numerous irregular black-edged olive cross-bands, with irregular serrated and torn edges; head olive, varied with two or three white spots in the centre of the crown, and a broad short band behind each eye. Several specimens of this species are in the British Museum, brought from Port Essington, Swan River, and other parts of Australia.

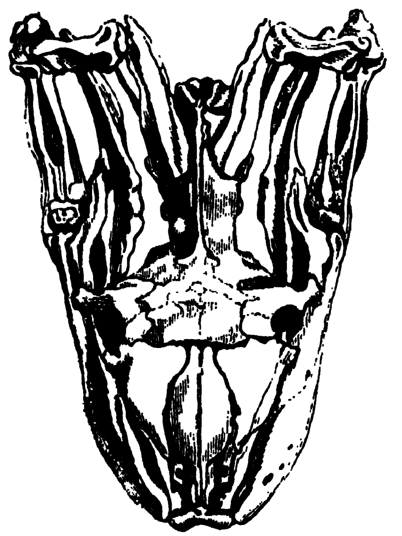
** Crown of head shielded to behind the eyes.

2. *Python.* Upper and lower labial shields deeply pitted; muzzle and forehead with symmetrical shields; nostrils vertical.

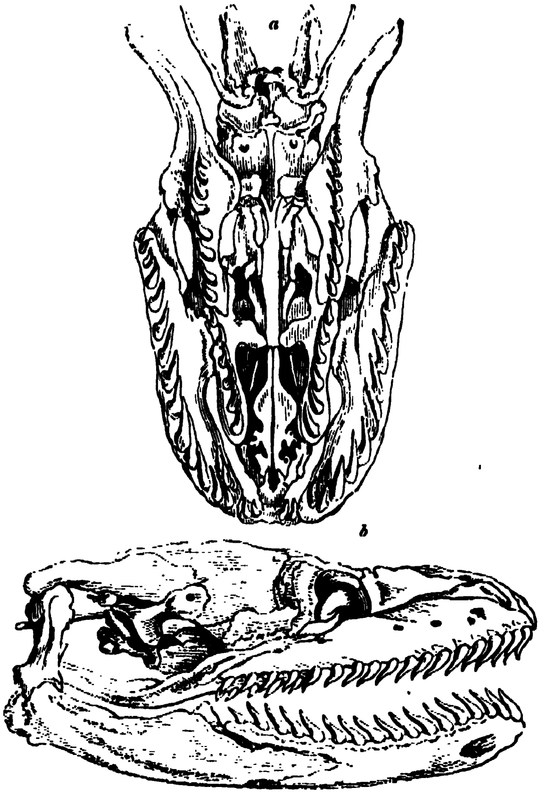
There are two species of this genus which have been referred to by many writers as varieties of *Boa Constrictor*. They are distinguished by placing their eggs in a group and covering them with their body. This statement, which was made by Mr. Bennett, and afterwards confirmed by M. Lamare Picquot, has been doubted, but its truthfulness has been confirmed by the proceedings of a python in the Garden of Plants at Paris.

P. reticulatus, the Ular Sawad, is distinguished from the next species by the four front upper labial plates being pitted; the frontal plate simple; the head has a narrow longitudinal brown stripe. It is one of the most brilliant species of the whole family, its whole body being covered with a gay lacing of gold and black. It is a native of Hindustan, Ceylon, and Borneo. Several specimens are in the British Museum, and a living specimen in the gardens of the Zoological Society, Regent's Park. It is said to increase till it is more than thirty feet in length and stout in proportion. The powers of such a gigantic reptile must be enormous, and it is stated that this serpent is able to manage a buffalo. Nor are there wanting horrible instances of man himself having fallen a prey to these monsters in modern times. The story goes that a Malay prow was anchored for the night under the island of Celebes. One of the crew had gone on shore to search for betel-nut, and is supposed to have fallen asleep upon the beach from weariness on his return. In the dead of the night his companions on board were roused by dreadful screams: they immediately went ashore, but they came too late; the cries had ceased, and the wretched man had breathed his last in the folds of an enormous serpent, which they killed. They cut off the head of the snake and carried it, together with the lifeless body of their comrade, to the vessel. The right wrist of the corpse bore the marks of the serpent's teeth, and the disfigured body showed that the man had been crushed by the constriction of the reptile round the head, neck, breast, and thigh. The picture by Daniell, representing a man seized by one of these monsters, will be familiar to many of our readers.

P. molurus (*Coluber molurus*, Linnæus, *P. Javanicus*, Kuhl, *P. Tigris*, Daudin), the Rock-Snake, is one of the species of this family often called by the name *Boa Constrictor*. It is characterised by having the two pairs of front upper and three hinder lower labial shields pitted, with the frontal plate double. The structure of the head and jaws of this species is seen in the annexed cuts, which will illustrate generally these points in the anatomy of the family. In the Museum of the College of Surgeons are several beautiful preparations of the structure of this gigantic snake. Four living examples are now in the Gardens of the Zoological Society, Regent's Park. This species is a native of Hindustan, Java, and other parts of Asia.



Head of *Python molurus*, seen from above.



Head of the same.
a, upper part of the head, seen from below; *b*, the skull, seen in profile.

3. *Hortulia.* Upper and lower labial shields deeply pitted; muzzle and forehead with symmetrical shields; nostrils lateral. There are three species natives of Africa:—

H. Natalensis (*Python Natalensis*, Andrew Smith), the Natal Rock-Snake. It has two pairs of front upper labial shields pitted, with two or three supra-ocular shields.

Dr. Andrew Smith, in his 'Illustrations of South Africa' gives a very beautiful figure of *Python Natalensis;* and he states that this snake, or at least one resembling it in size, was formerly an inhabitant of the districts now within the Cape Colony, and that the traditions of the older Hottentots abound with instances of its miraculous powers. "At present," he says, "it is not to be found within hundreds of miles of the boundaries of the colony, and few specimens have been obtained nearer than Port Natal." He informs us that it occasionally attains a very large size, and according to the natives, individuals have been seen whose circumference was equal to that of the body of a stout man. Dr. Smith himself saw a skin which measured twenty-five feet, though a portion of the tail part was deficient. "It feeds," he says, "upon quadrupeds, and for some days after swallowing food it remains in a torpid state, and may then be easily destroyed. The South Africans however seldom avail themselves of ridding themselves of a reptile they view with horror, as they believe that it has a certain influence over their destinies; and affirm that no person has ever been known to maltreat it without sooner or later paying for his audacity."

Rock-Snake (*Python molurus*).

H. Sebæ (*Coluber Sebæ*, Gmelin, *Python bivittatus*, Kuhl), the Guinea Rock-Snake and Fetish Snake, closely resembles the last in many points of structure. It is a native of western Africa, and specimens in the British Museum have been obtained from Ashantee, Gambia, and the Gold Coast. There is a living specimen in the Zoological Gardens, Regent's Park, estimated to weigh one hundredweight.

H. regia (*Boa regia*, Shaw, *Python regius*, Dumeril), the Royal Rock-Snake, distinguished from the last two by the four pairs of front upper labials being pitted, the supra-ocular plate single, the lower labial shields broad, four. It is an inhabitant of Gambia, in western Africa. It is of a black colour, marked on the middle of the back with a series of oblong longitudinal white spots; the sides with a series of very large white spots, with one or two oblong black spots on their upper part; the head black, with a streak over the nostrils and the top of the eyes, another from the lower edge of the eye; the lips, chin, and beneath white.

4. *Liasis.* Upper and lower labial shields pitted; muzzle and space between the eyes shielded. This genus includes various species of *Python* of other authors. Dr. Gray describes four:—

L. amethystinus, the Liasis; an inhabitant of New Ireland.

L. Macklotii, Macklot's Liasis, an inhabitant of Timor and Samao. Neither of these is in the British Museum.

L. Childrenii, Children's Liasis, an inhabitant of North-Western Australia. One specimen in the British Museum is from Port Essington.

L. olivacea, the Lisalia, also a native of Australia. Specimens have been brought from Port Essington and Sir Charles Hardy's Island.

5. *Nardoa.* Lower labial shields pitted; crown with eleven symmetrical shields. Of this genus there are two species, *N. Schlegelii*, the Nardoa of New Ireland, and *N. Gilbertii*, Gilbert's Nardoa, a native of North Australia.

b. Subcaudal plates entire, one-rowed; intermaxillary or incisive teeth none; supra-orbital bone none.

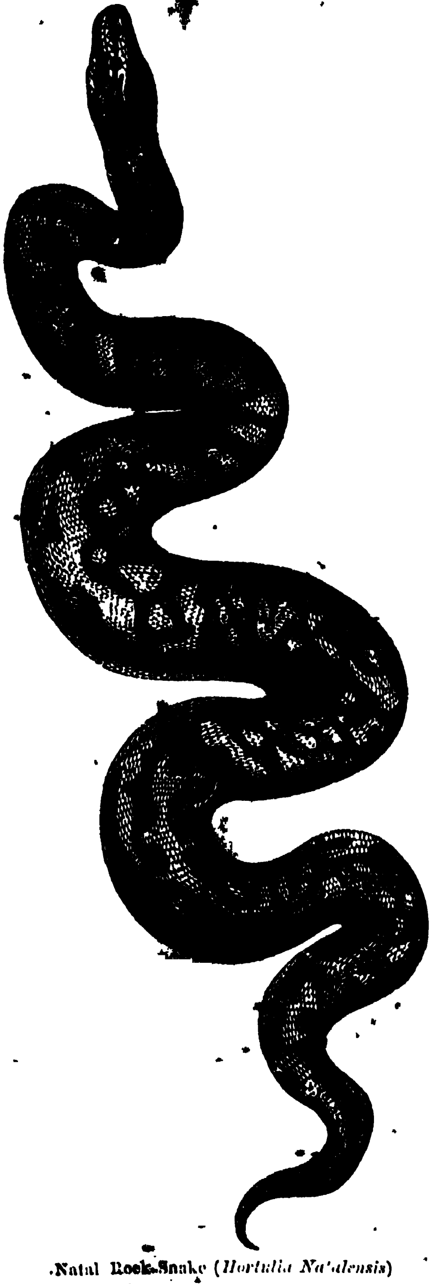
* Scales smooth; labial shields pitted.

6. *Epicrates.* Forehead with symmetrical shields; crown scaly. The species are natives of America and the West Indies.

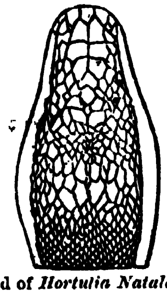
E. angulifer, the Pale-Headed Epicrates, is a native of Hayti.

E. Cenchria (*Boa Cenchria*, Linnæus, *Eunectes Aboma*, Cuvier), the

Aboma. It is one of the largest of the family, and sometimes attains a gigantic size. It is of a yellowish colour, with a row of large brown rings running the whole length of the back, and variable spots on the sides. These are generally dark, often containing a whitish semi-lunar mark. This species, according to Seba, who describes it as Mexican, is the Tamacuilcahuillia (or Tamacuilla Huilia, as Seba writes the word) described by Hernandez. This species haunts the marshy places of the warm parts of South America; there, adhering by the tail to some aquatic tree, they suffer the anterior part of the body to float upon the water, and patiently wait to seize upon the quadrupeds which come to drink.



Natal Rock-Snake (*Hortulia Natalensis*)

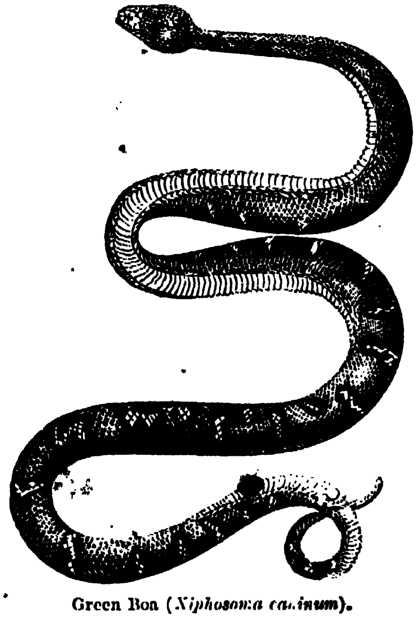


Head of *Hortulia Natalensis.*

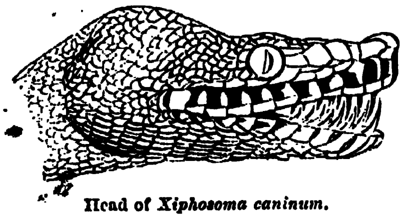
E. maurus, the Brown Aboma of Gray, is of a brown colour, and is a native of Venezuela.

7. *Xiphosoma.* Forehead and crown scaly; muzzle with regular shields; labial plates short and all pitted. There is but one species of this genus, *X. caninum* (*Boa canina*, Linnæus, *X. Araramboya* Spix), the Bojobi, or Green Boa. It is a native of America. It is greenish, with white irregular longish spots somewhat annularly

Aboma (*Epicrates Cenchria*).

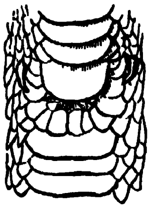


Green Boa (*Xiphosoma caninum*).



Head of *Xiphosoma caninum.*

disposed. This is the *Boa viridis* of Boddaert, the *Boa thalassina* of Laurenti, the Bojobi of the Brazilians, the Tetrauchoatl Tleoa (a Mexican name) according to Seba, and the Cobra Verde of the Portuguese, who relate that these serpents sometimes remain in the houses, doing no harm till irritated, when they at last bite and inflict a wound full of danger, not from injected poison, for the serpent has none, but on account of the injury sustained by the nerves from the very sharp, slender, and long teeth. Great inflammation follows, and the symptoms are aggravated by terror, so that a gangrene is the consequence unless the proper remedies are applied. In the absence of these, certain death is said to be the consequence of a severe bite from this serpent. The immediate cause of death is not stated by Seba, but from the long and penetrating teeth of the Bojobi it may be presumed to be often tetanus or locked jaw. Seba says that this species varies in size, adding that the specimen from which his figure was taken was more than two cubits in length. Cuvier is of opinion that the *Boa hipnale* is only a young Bojobi or *Boa canina*.



A portion of the under part of the tail of *Xiphosoma caninum*, showing the hooks near the vent, and the arrangement of the scuta.

Living specimens of this snake are in the Gardens of the Zoological Society, Regent's Park.

8. *Corallus*. Forehead and crown scaly; muzzle with regular shields; labial shields short, hinder ones pitted. There is but one species:—

C. hortulanus, the Cencoatl. It is most extensively distributed in South America, and amongst the specimens in the British Museum several varieties can be distinctly observed. This snake, which is the *Coluber hortulanus* and *Boa hortulana* of Linnæus, has been extensively observed, and has numerous synonyms.

9. *Sanzinia*. Forehead and crown scaly; muzzle with regular shields; labial shields elongate prismatic.

S. Madagascariensis, the Sanzin of Madagascar, is the only species, and of this a specimen exists in the Museum at Paris; there is none in the British Museum.

10. *Cliftia*. Forehead and crown scaly; muzzle with regular shields; labial shields broad, low. Dr. Gray remarks of this genus that it may be the same as *Casarea*, "but the scales in the dry specimens are not keeled; and the front upper labial shields appear to be pitted, and the tail is short."

C. fusca, a native of India, is the only species.

** Scales smooth; labial shields smooth, not pitted.

11. *Boa*. Crown covered with scales; nostrils lateral, between two plates. There are four species of *Boa*, all of which have been described as the *Boa Constrictor*, and it is always difficult to identify the particular species of snake referred to by travellers, on account of the loose manner in which the name is generally employed.

B. Constrictor of Linnæus (the *Boa Constrictrix* of Schneider, *Constrictor formosissimus* of Laurenti), the Boiguacu, is characterised by the scaly circle of the orbit being separated from the upper labial plates by one or two series of scales. It is also distinguished by a large chain extending the whole length of the back, composed alternately of great blackish stains or spots irregularly hexagonal, and of pale oval stains or spots notched or jagged at either end, the whole forming a very elegant pattern. Shaw, in his lectures, mentions a skin of this species measuring 35 feet, preserved in the British Museum, and adds, that it is probable that many ages ago much larger specimens might have occurred than any at present to be found, the increased population and cultivation of most countries having tended more and more to lessen the number of such animals. The locality of this species, according to the best authorities, is confined to the New World. Daudin, indeed, believed that it was found in the ancient continent, but without sufficient grounds for his opinion. Le Vaillant and Humboldt brought it from Guyana, and the Prince de Wied found it in Brazil. Cuvier gives it as his opinion that there are no true boas of large size in the Old World. All the specimens in the British Museum are from tropical America.

Linnæus, quoting Dahlberg, says that the *Boa Constrictor* was worshipped by the Americans.

"Snake-worship," says Dr. Southey, in his notes to Madoc, "was common in America." (Berna Dios, p. 3, 7, 125.) The idol described, vii. p. 25, somewhat resembles what the Spaniards found at Campeche, which is thus described by the oldest historian of the discoveries:—"Our men were conducted to a broade crosse-way, standing on the side of the towne. Here they show them a square stage or pulpit foure steppes high, partly of clammy bitumen, and partly of small stones, whereto the image of a man cut in marble was joyned, two foure-footed unknown beastes fastening upon him, which, like madde dogges, seemed they would tear the marble man's guts out of his belly. And by the image stood a serpent, besmeared all with goare bloud, devouring a marble lion, which serpent, compacted of bitumen and small stones incorporated together, was seven and fortie feete in length, and as thicke as a great oxe. Next unto it were three rafters or stakes fastened to the grounde, which three others crossed under-propped with stones; in which place they punish malefactors condemned, for proof whereof they saw innumerable broken arrowes, all bloudie, scattered on the grounde, and the bones of the dead cast into an inclosed courte neere unto it."—Pietro Martire.

This serpent appears to have been the Tlicoatl and Temacuilcahuilia of the Mexicans. "It derives its name," says Hernandez, "from its strength, for Temacuilcahuilia is, 'fighting with five men;' it attacks those it meets, and overpowers them with such force that if it once coils itself round their necks it strangles and kills them, unless it bursts itself by the violence of its own efforts;" and he goes on to state how its attack is avoided by the man opposing a tree or other object to its constriction, so that while the serpent fancies that it is compressing the man it may be torn asunder by its own act, and so die. The same author states that he had seen serpents as thick as a man's thigh, which had been taken when young by the Indians, and tamed, and how they were provided with a cask strewn with litter, in the place of a cavern, where they lived, and were for the most part quiescent except at meal times, when they came forth, and amicably climbed about the couch or shoulders of their master, who placidly bore the serpent-embrace (amplexus) of the terrific animal; or how, lying coiled up in folds, and equalling a large wheel in size, they harmlessly received the food offered to them. In the description of the Temacuilcahuilia we have, allowing for some exaggerations, the predatory habits of an enormous Boa; and in the relation of the manners of the tamed constricting serpents which follows it, we find an engine which might be and no doubt was turned to account by the ancient Mexican priests.

Boa Constrictor.

Specimens of this and the following species are living in the Gardens of the Zoological Society, Regent's Park.

B. diviniloqua (*Constrictor diviniloquus*, Laurenti), the Lamanda, is an inhabitant of Santa Lucia, and the specimen in the possession of the Zoological Society appears to be the only one in Europe.

B. Imperator, the Emperor Boa, is a native of Mexico and Honduras.

B. Eques, the Chevalier Boa, is an inhabitant of Peru.

12. *Pelophileus*. Crown covered with irregular plates; nostrils lateral, between two scales.

P. Madagascarensis, the Pelophile, a native of Madagascar, is the only species.

13. *Eunectes*. Crown covered with irregular shields; nostrils vertical, between three plates.

E. murinus (*Boa Scytale* and *Boa murina*, Linnæus, *Boa aquatica*, Prince Maximilian, *Boa gigas*, Latreille, *Boa Anaconda* and *Boa Aboma*, Daudin), the Anaconda. It is a native of tropical America.

Mr. Bennett observes in the 'Tower Menagerie' that the name of Anaconda, like that of *Boa Constrictor*, has been popularly applied to all the larger and more powerful snakes. He adds that the word appears to be of Ceylonese origin, and applies it to the *Python Tigris*.

This species is brownish, with a double series of roundish black blotches all down the back; the lateral spots annular and ocellated, the disks being white, surrounded by blackish rings. The trivial name *murinus* was given to it from its being said to lie in wait for mice; and Seba has given a representation of it about to dart upon an American mouse, which he says is its usual food. Such 'small deer' may be the prey of this species when very young, but it grows to a size equalling that of *Boa Constrictor* and *Epicrates Cenchria*. We think it very probable that this is the Culebra de Agua of the Venezuelans. The other provincial name, El Traga Venado, or 'Deer-Swallower,' indicates the prey of the serpent when of mature age. Linnæus says of his *Boa Scytale*, "Constringit et deglutit capras, oves," &c. (It constricts and swallows goats, sheep, &c.)

Anaconda (*Eunectes murinus*).

The following description of a species, of which a specimen was forwarded to the United Service Museum, was given by Sir Robert Ker Porter:—" It is not venomous, nor known to injure man (at least not in this part of the New World); however the natives of the plains stand in great fear of it, never bathing in waters where it is known to exist. Its common haunt, or rather domicile, is invariably near lakes, swamps, and rivers; likewise close to wet ravines produced by inundations of the periodical rains; hence, from its aquatic habits, its first appellation. Fish and those animals which repair there to drink are the objects of its prey. The creature lurks watchfully under cover of the water, and whilst the unsuspecting animal is drinking suddenly makes a dash at its nose, and with a grip of its back-reclining double range of teeth never fails to secure the terrified beast beyond the power of escape. In an instant the sluggish waters are in turbulence and foam, the whole form of the Culebra is in motion, its huge and rapid coilings soon encircle the struggling victim, and but a short moment elapses ere every bone is broken in the body of the expiring prey. On its ceasing to exist the fleshy tongue of the reptile is protruded (taking a long and thinnish form), passing over the whole of the lifeless beast, leaving on it a sort of glutinous saliva that greatly facilitates the act of deglutition, which it performs gradually by gulping it down through its extended jaws—a power of extension of them it possesses to so frightful and extraordinary a degree as not to be believed when looking at the comparative smallness of the mouth and throat in their tranquil state. After having completely devoured or rather hidden its prey in the way described it becomes powerless as to motion, and remains in an almost torpid state for some days, or until nature silently digests the swallowed animal. The snake now sent was killed with lances when just regarding its powers of action.

"The flesh of this serpent is white, and abundant in fat. The people of the plains never eat it, but make use of the fat as a remedy for rheumatic pains, ruptures, strains, &c. When these creatures are young the colours on the skin are very bright, and gradually lose their brilliancy with age."

There is generally in these descriptions an account of the fleshy tongue of the reptile, and of its application to the dead animal for the purpose of covering it with saliva, previous to the operation of swallowing it. A glance at the tongue of a Boa or a Python will convince the observer that few worse instruments for such a purpose could have been contrived. The delusion is kept up by the mode in which these serpents are sometimes preserved in museums, where they may be occasionally seen with fine artificial, thick, fleshy, vermilion tongues in the place of the small dark-coloured extensile organs with which nature has furnished them. We have frequently watched constricting serpents while taking their prey, and it is almost superfluous to add that they never covered the victim with saliva from the tongue before deglutition. When the prey is dead and the serpent is about to swallow it, the tongue of the destroyer is frequently thrust forth and vibrated, as if indicatory of the desire for food; but the mucus is not poured out till it is required to lubricate the dilated jaws and throat for the disproportioned feast.

14. *Chilabothrus.* Crown covered with regular shields; nostrils lateral, between three scales.

C. inornatus, the Yellow Snake, is a native of Jamaica. The head and front part of the body olive; temple with a narrow black streak; back with small scattered black oblique cross lines; hinder part of the body black, with olive spots. A living specimen is in the Gardens of the Zoological Society.

*** Scales keeled; lateral shields not pitted; nostrils between two plates.

15. *Ungalia.* Head covered with symmetrical shields. The species are natives of tropical America.

U. melanura, Black-Tailed Ungalia, has been found in Cuba.

U. maculata, the Pardaline Ungalia, is found in Cuba and Jamaica.

**** Scales keeled; lateral shields not pitted; nostrils a single plate.

16. *Enygrus.* Head covered with small irregular shields; nostrils in a single plate. There are two species, inhabitants of the Asiatic islands.

E. carinatus, the Candoia. It has been found in New Guinea.

E. Bibroni. Bibron's Enygrus. A specimen exists in the Museum at Paris.

17. *Casarea.* Head scaly; muzzle covered with symmetrical shields; nostrils in a single plate (?). One species,

C. Dussumieri, the Casarea, is found in the Isle Ronde near Mauritius.

18. *Bolyeria.* Head covered with symmetrical shields; nostrils in a single plate.

B. multicarinata, the Bolyeria, is the only species. It is a native of Port Jackson, Australia.

II. *Tail very short, slightly or not prehensile; Head indistinct, short.*

a. Head covered with scales; pupil oblong; scales convex; subcaudal shield one-rowed; intermaxillary teeth none; supra-orbital bone none.

19. *Cusoria.* Muzzle rounded; ventral and subcaudal plates narrow; scales ovate, of body and tail smooth.

C. elegans, the Cusoria, is the only species. Inhabits Affghanistan.

20. *Gongylophis.* Muzzle wedge-shaped; jaws equal; head with small keeled scales; scales of back keeled; body fusiform.

G. conica (*Boa conica*, Schneider; *B. ornata*, Daudin; *Eryx Bengalensis* and *Scytale coronata*, Guerin), the Padain Cootoo. It is a native of Hindustan.

21. *Eryx.* Muzzle wedge-shaped; upper jaw largest; head with small scales; scales of back smooth, of hinder part of body keeled.

E. Jaculus (*Tortrix Eryx*, *Anguis Jaculus*, *A. colubrina*, Linnæus; *A. cerastes*, Hasselquist, *Eryx Delta*, Geoffroy), the Eryx. This species, known by its distinct gular groove and two pairs of frontals, has been found in Egypt, Corfu, Xanthus, Naxos, Greece, and on the shores of the Mediterranean.

E. Thebaicus, the Shielded Eryx, has no gular groove, and one pair of frontals. It is a native of Egypt and the North of Africa.

22. *Clothonia.* Muzzle wedge-shaped; upper jaw largest; scales smooth.

C. Johnii (*Boa Johnii*, Rüppell, *Eryx Johnii*, Dumeril, *Tortrix Eryx*, Schlegel, *Amphisbæna*, 'Penny Cyclopædia,' *fig.*), the Clothonia, is the only species belonging to this genus.

This species is of a reddish brown colour, and is a native of Hindustan.

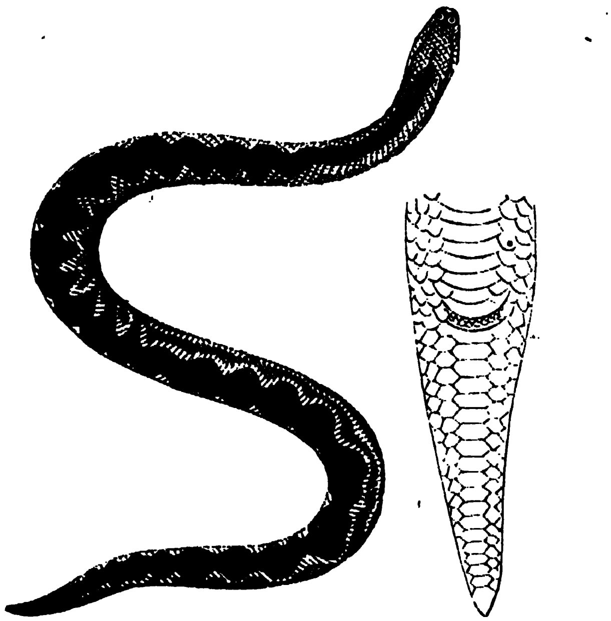
b. Head shielded; pupil round.

23. *Cylindrophis.* Nostrils in a single shield; eyes surrounded by shields; intermaxillary teeth none. This genus has three species.

C. melanota, the Black-Backed Pamboo. It has a triangular truncated tail. The muzzle is black, the end of tail white; the belly black and white banded; the tail longer than the head. It is a native of Celebes.

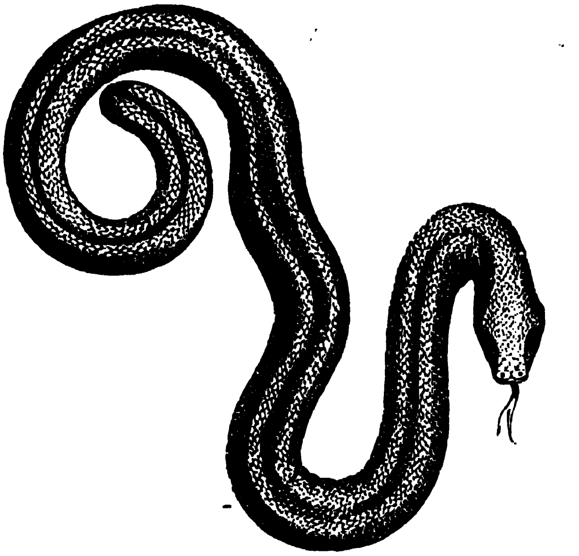
C. rufa, the Schilaj Pamboo, with a conical tail and broad muzzle. It is black or reddish, often white-ringed; head and tip of tail black;

a white spot on each fronto-nasal plate. It is a native of Penang. Dr. Gray describes two varieties, one from Borneo, another from Colebes.



Padain Cootoo (*Gongylophis conica*).

C. maculata (*Tortrix maculata*, Schlegel; *Anguis tesselata*, *A. derupata*, Laurenti), the Miguel, has a conical tail and narrow muzzle. It is red or brown, netted with black; beneath whitish. It inhabits Ceylon.



Clothonia (*Clothonia Johnii*).

24. *Charina.* Nostrils between two shields; eyes surrounded by small scales.

C. Bottæ (*Tortrix Bottæ*, Blainville), the Charina, is the only species. It is of a pale yellow colour, with back and tail darker. It is found in California.

25. *Tortrix.* Nostrils between two shields; eyes in a single shield; intermaxillary teeth distinct.

T. Scytale (*Anguis Scytale*, Linnæus, *A. ater*, Shaw, *Tortrix corallinus*, Oppell), the Coral Snake. It is a native of tropical America.

BOIS DE COLOPHANE. [BURSERA.]

BOLBO'CERUS, a genus of Coleopterous Insects of the family *Geotrupidæ* (*Scarabæus* of Linnæus). The species of this genus are remarkable for their short compact form, above appearing almost spherical. The male is armed with an erect horn springing from the head, the female has merely a tubercle in the same part; the thorax has frequently four small horns, or tooth-like processes, arranged in a transverse line on the anterior part; the antennæ are eleven-jointed, the three terminal joints form a compact round knob, the middle joint being almost inclosed by the other two; one mandible is armed internally with two teeth, the other is simple; the anterior portion of the mentum is entire; the elytra are striated.

These insects live upon dung, and excavate cylindrical holes in the ground under the mass, in which they deposit their eggs enveloped in a ball of the excrement.

There are about sixteen species known: their most common colour is brown or yellowish, and sometimes black. In this country but two species have occurred, *B. mobilicornis* and *B. testaceus*. *B. mobilicornis* is of a pitchy black colour, and about one-third of an inch long; the head in the male sex has a recurved horn; antennæ with the club red; thorax punctured, and furnished with four tooth-like projections on the fore part; elytra striated; legs and body inclining to a red colour.

B. testaceus is entirely of an ochre colour; head with two tubercles; thorax sparingly punctured; elytra with punctured striæ. About the same size as the last, of which by some it is supposed to be a variety. Both of these species are very rare.

BOLDOA, a genus of plants belonging to the natural order *Monimiaceæ*. *B. fragrans* is the Boldu of Chili. It produces an aromatic succulent fruit which is eaten by the natives. The wood is very fragrant, and makes a charcoal which is preferred by the smiths of Chili to that from any other wood. The leaves are also very fragrant. The bark is employed in tanning. (Lindley, *Vegetable Kingdom.*)

BOLE, a hydrous silicate of Alumina, which occurs as an earthy mineral in amorphous masses in various countries, as in Armenia, Saxony, in Tuscany, at Sienna, in Ireland, and in Scotland in the Isle of Skye.

The colour of Bole is various, either yellow, brown, red brownish, or pitch-black. It is dull, has a greasy feel, and adheres to the tongue. Its fracture is conchoidal, yields to the nail, and the streak is shining. When put into water it readily absorbs it, emits bubbles of air, and falls to pieces. The Armenian Bole, according to Wiegleb, consists of

Silica	63·13
Alumina	22·67
Iron	11·00
Loss	3·20
	100·00

The Lemnian Bole, called also Lemnian Earth, was anciently an article of Materia Medica, and kept by apothecaries in small pieces under the name of Terræ Sigillatæ: these were impressed on one side with the figure of a goat, &c. According to Pliny it was also used as red pigment.

Klaproth found the composition of this Bole to be

Silica	66
Alumina	14·5
Oxide of Iron	6
Soda	3·5
Water	8·5
A trace of Lime and Magnesia	
	98·5

The only Bole at present used is as a coarse red pigment, for which purpose it is calcined and levigated, and vended in Germany under the name of Berlin and English Red.

These earths were formerly employed as astringent, absorbent, and tonic medicines. They might be slightly serviceable as absorbents, in the same way as putty powder is used in the present day, when sprinkled over excoriations of the skin. Any tonic power which they possessed was due to the oxide of iron, which is now administered in a purer state. These once celebrated articles have fallen into merited disuse: they are still however employed in the East, and occasionally as veterinary medicines in Europe, where earths of a similar kind are found abundantly among volcanic, basaltic, and the older calcareous rocks, and are called after the different countries in which they are found. Those which have less colour are called *Bolus alba*, are procured in Bohemia, Salzburg, &c., and consist of lithomarge, which is formed of silica and alumina with water, and a little oxide of iron. These substances are extensively employed to adulterate articles of food, as anchovies, cocoa, and other things having naturally a red colour. The Bole Armenian must not be confounded with the Lapis Armenius, which is a native carbonate of copper. The Terra Lemnia is sometimes employed to signify the pulp of the fruit of the *Adansonia digitata*, the Baobab, or Monkey-Bread, which is used as an astringent for the cure of dysentery by the inhabitants of Senegal.

BOLETO'BIUS, a genus of Coleopterous Insects of the section *Brachelytra* (M'Leay), and family *Tachyporidæ* (*Staphylinus* of older authors.) Generic Characters:—Head long and pointed anteriorly; antennæ with the basal joint rather long and slender; the three next joints slender, and nearly of equal length, the remaining joints gradually increasing in width to the last, inclusive; palpi rather long and slender; thorax narrower before than behind, the hinder angles rounded; elytra smooth, or indistinctly striated; body long, widest at the base, and tapering to a point at the apex; legs moderate, tibiæ spinose, the four posterior with long spines at their apices.

The species of this genus reside in *Boleti* and other species of *Fungi*, in which they occur in the greatest abundance, particularly when in a state of decay. They are all exceedingly active, and their smooth slender bodies and pointed heads render it an easy task for them to thread their way with rapidity through the putrescent *Fungi*.

B. lunatus (Linnæus) is one of the most beautiful and largest species of the genus, and is not uncommon. It is about a quarter of an inch long. The head is black; the antennæ have the three basal joints yellow, the remaining black, with the exception of the terminal joint, which is yellow; the thorax and legs are yellow; the wing-cases are of a blue-black colour, with an oblique yellow spot on the shoulders; the body is yellow, with the apex black.

About eighteen species of this genus have been found in this country, almost all of which are varied with yellow and black. Many have the wing-cases yellow, with two black spots, one on each side of the apex; some have also the region of the scutellum black.

(Stephens, *Illustrations of British Entomology.*)

BOLE'TUS, an extensive genus of *Fungi*, consisting, according to the old botanists, of leathery masses, which are sometimes of considerable thickness, and having the spores lodged in tubes which occupy the same situation as the plates in the gills (or hymenium) of the common mushroom. Fries, the great modern describer of *Fungi*, defines the genus thus:—Hymenium formed of a peculiar substance, altogether distinct from the cap, entirely composed of tubes united into a porous layer; these tubes are undivided, separable from each other, long, cylindrical, or angular, open from end to end, and bear asci (spore-cases) on their inside; asci cylindrical, with small roundish spores; the stalk is central, and often netted; the cap is fleshy, soft, spread out into a hemispherical form; veil present in many of them. He includes within his definition but a small number of the old *Boleti*, referring the principal part to *Polyporus*, which is especially characterised by having the tubes of its hymenium inseparable from the cap, which is more leathery, and usually without a stalk.

Boletus luteus.

The true *Boleti* are generally found growing on the ground in woods and meadows, especially in pine woods: the *Polypori* are commonly met with on trees, especially pollards. Of the former, several species are eatable, as *B. edulis*, *B. scaber*, *B. subtomentosus*, and *B. granulatus*; others are acrid and dangerous. Of these Dr. Badham, who has written on the Esculent Funguses of England, recommends only *B. edulis* and *B. scaber*.

B. edulis, the Edible Boletus, has the following characters:—Pileus or cap from six to seven inches across, smooth, with a thick margin varying in colour from light brown or bronze to bay, dark brown, or black, or a mixture of all these colours; the epidermis firmly adherent to the flesh, which is fine, and except the part in immediate contact with the skin, white; the under surface of the cap nearly flat, often presenting a circular pit or depression round the stalk; the tubes at first white, then yellow, lastly of an olive or yellow green tint, in the earlier stage of their growth closed; afterwards as the cap expands stopped up with a waxy-looking material of a dirty pearl-colour; stem varying much in shape at different periods of the growth of the Boletus, always thick and solid, at first white but soon changing to fawn-colour, beautifully netted with reticulations. As the period of the ripening of the spores advances the under part of the cap swells, the waxy matter is absorbed, the tubes present deep and rounded orifices to the eye, and emit an ochreous green dust, which consists of sporules. After this the whole fungus becomes flaccid, the tubes turn to a dirty green, and decomposition rapidly proceeds. This Boletus grows in woods consisting of pines, oaks, or chestnuts; it is most abundant in autumn, but occurs in spring and summer. Dr. Badham says of other *Fungi* likely to be comfounded with it:—"The *B. castaneus*, which bears some little resemblance to it, is at once distinguished by having a cottony fibrillose stem without reticulations, a downy cap, and dirty yellow dust: neither can it be confounded with the *B. subtomentosus* or *B. luridus*, because in addition to many other points of difference, both these change colour on being cut or bruised." As an article of diet, Dr. Badham says "It imparts a relish alike to the homely hash and the dainty ragout, and may be truly said to improve every dish of which it is a constituent."

B. scaber has a cap from three to seven inches across the surface, which becomes viscid when moist and is invariably downy. There are two varieties, in one of which the pileus is of a beautiful deep orange hue and the stem black. In the other the pileus is gray and the stem covered with orange scales. The flesh is thick and flabby, of a dingy white, not greatly changeable in young specimens, but deepening in colour when old. It is not so agreeable as the last species.

B. officinalis, supposed to have been the 'Αγαρικὸν of Dioscorides, is an old-fashioned medicine remarkable for the extreme acridity of its powder; it acts as a powerful purgative, but is never employed at the present day.

B. igniarius, when dried and sliced, furnishes the German Tinder, or Amadou, a leathery substance sold in the tobacconists' shops. [AMADOU.]

B. destructor is one of the many species of *Fungi* the ravages of which are too well known under the name of Dry Rot. Their destructive qualities are not however caused by the fructification, or the part which we commonly consider the fungus itself, but by the ramifications through the substance of the wood of what botanists call the Thallus and gardeners the Spawn of such plants, which is in effect their stem and root in a mixed state. Other species of *Fungi* produce dry rot. [MERULIUS.]

BOLITO'PHAGUS (Fabricius), *Eledona* of Latreille, Leach, and Millard, and *Opatrum* of some other authors, a genus of Coleopterous Insects of the section *Heteromeia* and family *Tenebrionidæ*. The principal generic characters are as follows:—Head short, partially hidden by the thorax, in the males sometimes armed with a horn or tubercle; antennæ very short and thick, the three or four apical joints much broader than the rest; maxillary palpi rather large and distinct, the terminal joint truncated, its length equalling that of the two preceding joints; labial palpi small; thorax coarsely punctured or rugose, the lateral margins more or less toothed; elytra deeply striated; legs short and thick, the anterior tibiæ compressed.

There are about six species of this genus known: they live in *Boleti*, and are of a small size, a short ovate form, and their prevailing colours are brown-black. In this country but one species has as yet been discovered, *B. Agaricola* or *Agaricicola*. It is of a brown colour, and about one-twelfth of an inch long. It is rather local, but where it does occur it is found in tolerable abundance.

BOLOGNA SPAR, a variety of Sulphate of Barytes. [BARYTES.]

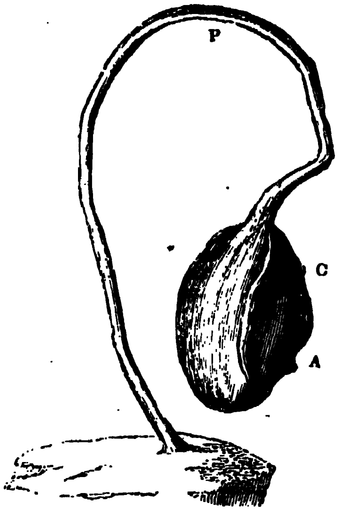
BOLSOVER STONE. The yellow limestone of Bolsover in Derbyshire is used in the construction of the new Houses of Parliament. It was selected for its durability, strength, fitness for ornamental work, and colour. It is a combination of carbonate of magnesia with carbonate of lime [DOLOMITE] in small granular crystals, without the slightest trace of organisation, flinty nodules, or other blemishes. It has been subjected to various and severe mechanical pressures, chemical re-agents, &c., and has sustained them with credit; but it is yet to be seen whether it can withstand the atmosphere of London, which has destroyed the Bath and Portland Oolites. Many other public buildings in England have been built with stone from the same formation, which is called Magnesian Limestone.

BOLTE'NIA, a subgenus of *Ascidiidæ*, a family of the group *Tunicata*, which, according to W. S. M'Leay, are the animals that connect the *Acrita*, or lowest primary division of the animal kingdom, with the *Mollusca*, from which he observes they differ in the following points: first, in having an external covering consisting of an envelope distinctly organised and provided with two apertures, of which one is branchial, the other anal; secondly, in their mantle forming an internal tunic corresponding to the outer covering or test, and provided like it with two openings; and thirdly, in having branchiæ which occupy all or at least part of the membranous cavity formed by the internal sides of the mantle. From the *Acrita* the *Tunicata* (or *Heterobranchiata*, as De Blainville calls them) differ in having distinct nervous and generative systems, while their intestinal canal is provided with two openings, both internal. [TUNICATA.]

The following is the generic character of *Boltenia* (Savigny) as reformed by M'Leay:—Body with a coriaceous test, supported from the summit by a long pedicle, and having both orifices lateral and cleft into four rays. Branchial pouch divided into longitudinal folds, surmounted by a circle of compound tentacula, and having the reticulation of its respiratory tissue simple; abdomen lateral; ovary multiple.

There are three species recorded, namely, *B. ovifera*, *B. fusiformis*, and *B. reniformis*.

The following is M'Leay's character and description of *B. reniformis* (*Ascidia globifera*, Sabine, *A. clavata*, Fabricius):—Obscure, roughish; body sub-reniform, the orifices being somewhat prominent; peduncle terminal; envelope sub-pellucid, whitish; mantle or tunic very thin, provided with transverse circular narrow muscles, which cut each other very obliquely; tentacula about ten or twelve in number, very unequal, clavate, with the clava plumiform, or beautifully divided into a number of regular laciniæ; branchial pouch marked with about fifteen or sixteen large folds, and having the net-work simple and regular; dorsal sulcus having the two lateral filaments winged and the intermediate simple; œsophagus descending vertically to the lower end of the body, as suspended, and there meeting an ascending ovoidal stomach without any apparent internal folioli; intestine with an oblong, longitudinal, open loop, which is prolonged to the pedicle; rectum narrow, subconical, and ascending nearly parallel to the œsophagus, only higher; anus having a scolloped margin; liver coating the stomach behind the right ovary, and running from the lower end of the body, as suspended, about half way up; it is divided into several granulated globes, some of which are separated from the others, particularly towards the pharynx; ovaries two, elongate, lobate, situated on each side of the body, and directed towards the anal orifice; right ovary straight, claviform, lying close within the loop of the intestine; left ovary larger and less lobate, but undulated and extending downwards behind the branchial vein.



Boltenia reniformis, from a preserved specimen.

P, pedicle; C, branchial orifice of envelope; A, anal orifice of envelope.

M'Leay gives the northern seas of America as the locality of the animal. Captain J. C. Ross says that a single specimen was dredged up from a depth of seventy fathoms near Elizabeth Harbour. He observes that he can add nothing to M'Leay's admirable description except that the colour of the body is a very light brown; that of the pedicle darker.

The sphere wherein this Ascidian moves must necessarily be very contracted. Anchored by its pedicle, the length of its moorings fixes the limit of its motions, which are most probably confined to the oscillations arising from the agitation of the waves. Both the body and pedicle, as M'Leay observes, are scabrose, or covered with a rough surface, which is formed by exceedingly short coarse hairs. The original colour he could not ascertain; but in spirits it was cinereous, or dirty white, which, he adds, may possibly be the true colour of the animal, as it is not unfrequently that of the other *Ascidiadæ*. M'Leay's specimen was brought home from Winter Island by W. N. Griffiths, Esq., while under the command of Captain (now Sir Edward) Parry.

BOLTONITE, a native anhydrous Silicate of Magnesia. It occurs massive with a granular structure, or in yellowish or bluish-gray grains. The cleavage is in one direction; the lustre vitreous; transparent to translucent. It is found disseminated through limestone in the United States of America, at Bolton, Roxborough, and Nittleton, Massachusetts; and Ridgefield and Reading, Connecticut.

BOMBA'CEÆ, a group of plants considered by some a distinct natural order, by others as a mere section of *Sterculiaceæ*. They are usually large trees, with broad deep-green leaves, and flowers of considerable size. Technically they differ from *Malvaceæ* in having two cells to their anthers which are often doubled down upon themselves, in their calyx opening in an irregular rather than a valvate manner, and in their stamens being usually collected into five parcels. Their anthers are often described as having only one cell; but this is an inaccurate mode of speaking of them, inasmuch as they are formed upon the common two-celled type, and merely have the cells united at the point of the connective.

This group contains some of the most majestic and beautiful trees that are known, but nothing of much medical or economical importance is furnished by them. Their wood is light and spongy; the long cottony substance found within their fruit, and which has gained for some of them the name of Cotton-Trees, is too short in the staple to be manufactured into linen; and the slightly acid or mucilaginous qualities that occur in the group are altogether inferior to those of many *Malvaceæ*. The Baobab Tree is one of them. [ADANSONIA.] It is remarkable for the excessive thickness of its trunk as compared with its height, and this is a character of common occurrence. Several American species spread enormously near the ground, forming huge buttresses with the angles of their trunks. This is especially the case with the genus *Eriodendron*, which is moreover often defended by very large conical prickles, which do not fall off till they are exfoliated by the gradual distension of the trunk. Among these plants is a singular instance of a flower resembling the paw of some animal. [CHEIROSTEMON.] No bombaceous plants are found far beyond the tropics.

BOMBAX (from βόμβυξ), a genus of plants, the type of the natural order *Bombaceæ*. It has a naked, campanulate, unequally 2-5-lobed or truncately 5-toothed calyx; five petals joined together, and somewhat connected at the base with the column of the stamens; numerous stamens, monadelphous at the base, but free at the apex; the anthers inserted at the middle, kidney-shaped or oblong, opening above by a transverse chink; the capsules large, 5-celled, 5-valved, woody; cells many-seeded; albuminous seeds surrounded by silky cotton. The species of this genus are large trees with a soft spongy wood, which is frequently used for making canoes. They are natives of South America and the East Indies.

B. Ceiba, Common Silk-Cotton Tree, has a prickly trunk, palmate leaves with five leaflets, turbinate fruit concave at the apex. This plant is a very large tree, and is a native of the West Indies and South America. Some of the older travellers gave extravagant accounts of its height; it is however frequently seen reaching above 100 feet. The down, which is contained in the seed-vessel, is very soft, but is too short to be used in the manufacture of cloth. It is made into hats and bonnets, and used for stuffing chairs and pillows by the poor people in the districts in which it grows. It is not made into beds, as it is reputed unwholesome to lie upon. The trunks of the largest are made into canoes, and some of these will carry from fifteen to twenty hogsheads of sugar. Columbus in his first voyage to America speaks of having seen a canoe made of this tree in Cuba, which contained 150 men. When the stem decays it becomes the prey of the larva of the Macaca Beetle, which when gutted and fried is esteemed as a great delicacy in the districts where it occurs.

B. pubescens has an unarmed trunk, the lower leaves quinate, the upper ones ternate; the leaflets obovate, elliptical, emarginate, coriaceous, smooth, or covered with black dots of stellate pili beneath; the pedicles inflated and hollow under the flower, and as well as the calyxes covered with black dots of stellate tomentum; the petals tomentose, three times longer than the calyx, with a smooth ovary. This plant reaches from 20 to 30 feet in height. It is a native of Brazil, in the province of Minas Gernes, where the tree is called Embirussu. The bark is very tough, and is used for making ropes. The other species of *Bombax*, of which from fourteen to twenty have been described, possess the same general qualities as the two species described. The wool of the pods of the *B. Malabaricum* is used in India to stuff pillows and beds. *B. insigne* is a native of the Birman Empire, and is remarkable for its large red very showy flowers. All the species grow best in a rich loamy soil. Cuttings not too ripe, when taken off at a joint, will root freely in sand under a hand-glass in a moist heat. The best mode of propagating them is from seeds brought from the places of their natural growth. None of the species seem to have flowered in stoves, but this arises probably from the want of height.

(Burnett, *Outlines*; Loudon, *Encyclopædia of Plants*; G. Don, *Gardener's Dictionary*.)

BO'MBUS, the generic name of those Insects commonly called Humble-Bees: this latter name was derived (Messrs. Kirby and Spence conjecture) from the German Hummer- or Hummel-Biene, a name probably given to these insects from the humming sound which they emit. The *Bombi* belong to the order *Hymenoptera* and family *Apidæ*, and as regards the English species are by far the largest of the tribe. They may be distinguished by the following characters:—Body thickly covered with hair; head with a longitudinal groove and an indentation extending across from the upper part of the eyes; in this indentation the three stemmata are placed, being arranged nearly in a straight line; and it is from the central stemmatum that the longitudinal groove has its origin, whence it extends downwards; antennæ with twelve joints; labrum with its surface uneven; mandibles with several longitudinal grooves on the upper side; posterior tibiæ compressed, smooth, margined with strong recurved hairs, and armed with spines at the apex.

The above are the peculiarities of the females. In the males the antennæ are thirteen-jointed and considerably longer than those of the other sex; the hinder tibiæ want the corbicula; the mandibles are bidentate at the apex and each furnished with a tuft of curved hairs; they differ likewise in possessing no sting and in the structure of their claws, but these two last characters are common to the whole tribe of *Apidæ*.

The neuter bees resemble the females in every respect excepting size; in this they are inferior to the males, which latter are rather less than the females.

Kirby, in his monograph on the bees of this country, enumerates 37 species as belonging to his section '*. * c. 2:' this section, with the exception of a few species [PSYTHIRUS], now constitutes the genus of which this article treats.

The prevailing colours of the species are yellow, red, and black: and as these colours are disposed with a certain degree of uniformity, we have arranged the following, which form the principal part of the British species, under three heads, namely, those which have the apex of the body more or less red, those which have that part white, and those in which the ground-colour of the body is yellow or buff: by this arrangement much repetition in the descriptions is avoided.

Section I. *Apex of the Body red.*

B. lapidarius (female), black. The male is rather long and narrow; head and anterior and posterior portions of the thorax yellow.

This species, well known by the name Red-Tailed Bee, is one of the largest and commonest of the genus; the females are to be seen in the spring and summer months; in the autumn, when the males make their appearance, they are less common.

B. Raiellus (female). Smaller and shorter in proportion than the last, from which it may moreover be distinguished by having red hair on the hinder tibiæ.

B. Derhamellus, colour ashy-brown. Thorax and abdomen each with a black fascia. Most probably the male of the last described.

B. subinterruptus (female), black. Anterior portion of the thorax yellow; abdomen with a subinterrupted fascia of the same colour towards the base.

B. Pratorum, black. Anterior portion of the thorax yellow.

B. Burrellanus (male), yellow. Thorax with the central portion black; abdomen with a black fascia near the middle.

B. Cullumanus (male). Like the last, but the fascia of the abdomen is very narrow, occupying only one segment.

B. Donovanellus (female), black. Thorax with the anterior portion yellow; abdomen with the basal portion yellow. In the male the anterior portion of the thorax is obscurely coloured.

Section II. *Apex of the Abdomen white.*

B. terrestris.—This is the largest and most common of the yellow and black Humble-Bees. It has the anterior margin of the thorax and the segment next the basal one of the abdomen of a yellow or buff colour; the rest of the body is black, with the exception of the apex, which is sometimes of a dirty yellow colour and at others white.

The neuters of all the species are very variable in size, but in this there appears to be the greatest extreme; we have specimens which are scarcely as large as the common hive-bee.

B. Hortorum, black. Thorax with the anterior and posterior portions yellow; abdomen with the base yellow; rather less than the preceding species.

B. Tunstallanus (female), black. Thorax with the anterior and posterior margins narrowly edged with yellow.

The insect described by Kirby under the name of *Latreillella* has lately been discovered by Mr. Pickering to be the male of this species. It is of a pale yellow colour, with the central portion of the thorax and two indistinct fasciæ towards the base of the abdomen black.

B. Jonellus (male), yellow. Thorax and abdomen each with a black fascia.

B. lucorum (male), yellow. Thorax with the central portion black; abdomen with the two basal segments yellow, and the two following black, the remainder white.

Section III. *Ground-Colour of the Body yellow or buff.*

B. Muscorum, yellow. Thorax orange.

B. floralis, yellow. Abdomen with a black spot on each side of the second segment, the three following segments with their bases black.

B. Beckwithellus, pale buff colour. Thorax and apex of the abdomen reddish yellow, the latter with a black fascia in the middle.

B. Curtisellus. Like the last, but the abdomen is black, with the base of reddish-yellow.

B. Fosterellus. Thorax buff coloured, with the anterior part blackish; abdomen with three obscure black fasciæ.

(Observation.—We have reason to believe the last four to be varieties of the same species.)

B. Sylvarum, yellowish-white. Thorax with a black fascia; abdomen with two black fasciæ; the apex red interspersed with white.

B. fragrans, bright yellow. Thorax with a black fascia.

Of the above species, *B. terrestris* and *Lapidarius* are the largest. *B. fragrans*, *Tunstallanus*, and *Hortorum*, are the next in size. All the rest of the species are nearly of a size, with the exception of *B. Pratorum.*

The habits and economy of these insects are not less interesting than other members of the order *Hymenoptera.*

In the autumnal months, when the cold weather begins to be felt, and the various honey-yielding flowers disappear, the male and neuter Humble-Bees die, having performed their allotted task, which as far as we can discover, appears to be that of fecundating certain plants, by conveying the pollen from the male to the female flowers: a task which is unavoidably accomplished by their visiting different flowers for the purpose of collecting honey and pollen to rear their young. Some female Humble-Bees also die, whereas others (probably those only which had been reared in the previous summer) seek a convenient spot in which they may pass the winter as little exposed to the cold as possible; sometimes in rotten wood of old pollard trees, and sometimes in moss, or among dead leaves, or in fact in almost any situation which will afford the desired protection. Here they remain in a torpid state and without food. The warmth of the spring causes these females again to make their appearance, and having been impregnated the previous autumn, they seek a convenient spot wherein they may construct their nests. Grassy banks are the localities most frequently chosen for this purpose, but various situations, and even a difference of soil apparently, are selected by the different species of Humble-Bees; for we observe certain species abounding more in one situation than another, and that in places distant from each other but similar in character. The nests are sometimes built upon the ground, but most generally they are in a hole excavated by the bee. These excavations vary in depth and form, even though made by the same species of bee. In their construction the animal uses its jaws to dislodge the particles of earth, which are then, by means of the anterior pair of legs, passed backwards to the hinder pair, which perform the same office: but as the burrow becomes deeper, the whole body of the bee is used to eject the grains of soil. In saying that the Humble-Bees form the burrows in the ground in which we find them, we speak upon the authority of Réaumur, for although we have frequently observed the female bee commence removing particles of earth, apparently with intent to make such an excavation, upon returning to the same spots after a sufficient interval of time, the work was always abandoned. Huber, who paid much attention to these insects, says, "I have not discovered in what manner they excavate the holes which lead to their nests, nor do I know how they form the vaults in which they are placed, neither am I aware whether they always construct these vaults themselves, or whether they do not sometimes avail themselves of the holes made by moles or other animals." Upon consulting some other authors, these points appear to be treated of in too vague a manner. When a small cylindrical but generally tortuous gallery is formed, it is terminated by an arched chamber of considerable extent, and it is in this chamber that the nest is constructed. Those species which do not burrow in the ground choose a situation in which the herbage is sufficiently thick to afford shelter, and there form on the surface of the ground an arched chamber of moss thickly matted together. In what manner the female first commences the interior arrangement of her nest, and how she brings up her young whilst in her solitary state, Huber and some of the earlier authors did not ascertain. We are indebted to M. le Comte Saint-Fargeau for this portion of the present history. This author informs us that having collected a quantity of pollen and honey, these substances are formed by the female humble-bee into a ball, in which the eggs are deposited, so that when the eggs are hatched the larvæ are surrounded by the substance, which serves them both for food and protection. The balls generally contain numerous eggs, and consequently when these are hatched numerous larvæ. Réaumur found them to vary from three to thirty. Each larva feeding upon the food nearest to it, the original crust of their enclosure becomes thin, and the parent insect then takes care to add fresh alimentary paste to the weakest parts. When the larvæ are full grown each one incloses itself in a silken cocoon of an oval form and placed always in a perpendicular position. A certain number of neuters, or workers, having undergone their final transformation, the nest is enlarged, and an inner coating of wax is attached to it, and in those nests which are constructed with moss the particles of wax are so amalgamated with it that a portion of the moss cannot be removed without injuring the interior more or less. Wax is also used by the workers in the construction of little cells for the reception of honey. Each species of Humble-Bee makes these cells, as Huber informs us, in a different manner; some construct them on the top of the cocoons, and of a half oval form; others build them of an egg-shape, with the apex truncated. In some again they resemble the first, but have a ring of wax within the top. The next variety is almost a perfect oval, having but a small opening at the apex. Lastly, these Humble-Bees show, says Huber, "that they are not inferior to the hive-bee in the art of economy. Between four honey-pots there would necessarily be a vacant space; but this is occupied by a fifth reservoir, which is not of the same form as those by which it is surrounded, but sometimes approaches to a square," &c. As an instance of the intelligence of these bees, Huber relates that when a bee is prevented from obtaining the honey at the bottom of the flower by the tube of the corolla being too narrow and deep, they drill a hole with their proboscis through the calyx and corolla right into the tube, and in this manner tap the vessel containing the liquid of which they are so fond.

The male Humble-Bees are not reared till late in the season, and do not appear in any abundance till the autumn. As in the case of the hive-bee therefore, they take no part in the duties of rearing the young, which it appears are almost entirely under the protection of the neuters as soon as they are hatched.

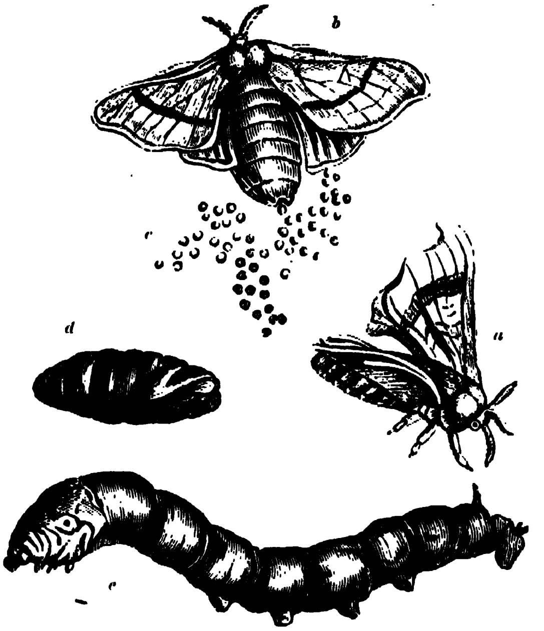
When the nest is tolerably well peopled, it presents a mass of oval cocoons spun by the larvæ as before described; interspersed with which there are numerous masses of an irregular but generally somewhat rounded form, and of a brown colour: some of the largest are about the size of a small walnut. Each of these masses incloses either eggs or larvæ, and is composed of pollen mixed with honey. To these must be added the little honey-pots which are irregularly interspersed with the cocoons.

BOMBY'CIDÆ, a family of Insects of the order *Lepidoptera*, belonging to the section *Lepidoptera nocturna* of Latreille, or Moths.

The principal characteristics of this family are—their possessing only rudimentary maxillæ, remarkably small palpi, and bipectinated antennæ.

Some of the species fly very rapidly, and make their appearance in the day-time as well as in the evening. The caterpillars of most of the species are hairy (some produce great irritation to the hand when touched), and assume the pupa state in a cocoon spun for its protection. The pupa is simple.

One of the most interesting of the family is the *Bombyx Mori*, well known as the moth to which the Silkworm turns. This species which was originally from China is of a white or cream colour, with a brown fascia and two or more waved lines of a deeper colour crossing the upper wings. In this country the eggs of this moth hatch early in May; the caterpillar or silkworm is at first of a dark colour, but soon becomes light, and in its tints much resembles the perfect insect, a circumstance common in caterpillars. Its proper food is the mulberry, though it will likewise eat the lettuce and some few other plants; on the latter however it does not thrive equally well, and the silk yielded is of a poor quality.



a and *b*, *Bombyx Mori*; *c*, the eggs; *d*, the pupa; *e*, silkworm or caterpillar.

The Silkworm is about eight weeks in arriving at maturity, during which period it changes its skin four or five times. When about to cast its skin it ceases to eat, raises the fore part of the body slightly, and remains in perfect repose. In this state it is necessary that it should continue for some little time, in order that the new skin, which is at this time forming, may become sufficiently mature to enable the caterpillar to burst through the old one. This operation, which is apparently one of considerable difficulty, is performed thus:—the fore part of the old skin is burst; the silkworm then by continually writhing its body (but not moving from the spot) contrives to thrust the skin back to the tail, and ultimately to disengage itself altogether; this last part of the operation however is the most difficult, since it is no uncommon occurence for them to die from not being able to disengage the last segment of the body from the old skin.

Those who have reared silkworms must have observed how large the head is in proportion to the body in those which have just changed their skins; this circumstance is worthy of observation, for in it will be found a most beautiful contrivance.

When the larva of an insect has just changed its skin, every part is soft, and in many cases (such as caterpillars) the greater portion of the body still remains in this flexible state; but the skin of the head and some few other parts in all instances soon become hardened, after which it never grows. The same happens with those larvæ which have the body in a great measure covered with hard plates, which circumstance leaves no parts to enlarge but such as are flexible. In the instance of a caterpillar the body increases in size rapidly after change of skin, but the head it will be observed does not enlarge, and although the body may have increased very much it does not appear that the skin has grown; it seems only to be stretched with the increase of size of the inner parts. In the case of those larvæ which have the body covered with hard plates, it is the skin between the plates that stretches to allow of growth in the inner parts, so that just before changing skin all the plates are considerably separated.

From the above we conclude that the external covering of insects does not grow at all, except at the time of repose previous to the casting off the old skin, after which operation the head and those parts which soon become hard are sufficiently grown to last until the next change; and also that the soft parts of the external covering will bear stretching to a certain extent and no further when it becomes necessary that they should change that covering for a larger one. With respect to the silkworm and other caterpillars, an unobserving person would not readily understand how the head, which is much larger than the one the case of which has just been cast off, can have come out of it; but if the silkworm be examined just before it is about to change its skin, it will be seen that such is not exactly the case, for part of the new head may be seen thrust out behind the old one, so that the fore part only is inclosed by the latter.

When full grown the silkworm commences spinning its web in some convenient spot, and as it does not change the position of the hinder portion of its body much, but continues drawing its thread from various points and attaching it to others, it follows that after a time its body becomes in a great measure inclosed by the thread. The work is then continued from one thread to another, the silkworm moving its head and spinning in a zigzag way, bending the fore part of the body back to spin in all directions within reach, and shifting the body only to cover with silk the part which was beneath it. As the silkworm spins its web by thus bending the fore part of the body back, and moves the hinder part of the body in such a way only as to enable it to reach the farther back with the fore part, it follows that it incloses itself in a cocoon much shorter than its own body, for soon after the beginning the whole is continued with the body in a bent position. From the foregoing account it appears that with the most simple instinctive principles all the ends necessary are gained. If the silkworm were gifted with a desire for shifting its position much at the beginning of the work it could never inclose itself in a cocoon; but by its mode of proceeding, as above explained, it incloses itself in a cocoon which only consumes as much silk as is necessary to hold the chrysalis.

During the time of spinning the cocoon the silkworm decreases in length very considerably, and after it is completed, it is not half its original length; at this time it becomes quite torpid, soon changes its skin, and appears in the form of a chrysalis. The time required to complete the cocoon is about five days. In the chrysalis state the animal remains from a fortnight to three weeks; it then bursts its case and comes forth in the imago state, the moth having previously dissolved a portion of the cocoon by means of a fluid which it ejects.

The moth is short-lived; the female, in many instances, dies almost immediately after she has laid her eggs; the male survives her but a short time.

The silkworms, which are most extensively reared for the purpose of producing silk [Silk, in Arts and Sc. Div.], are liable to many diseases, and none have been more destructive than that called muscardine. This disease attacks the caterpillar when about to enter the chrysalis state. It is always attended with the development within the body of a minute fungus closely resembling our common mould. It is probable the fungus only attacks those worms which are predisposed to disease, but in certain seasons this fungus has been so extensively developed as to lead to the supposition that it produces the disease itself. It is very certain that, when this fungus is prevailing and its spores are introduced into the body of the silkworm, it becomes rapidly diseased and dies. The fungus spreads internally before the death of the worm and afterwards it shoots forth from the surface of the skin. The chrysalis and moth will have the disease if inoculated with the fungus, but it only occurs spontaneously on the caterpillar.

BOMBYCILLA, a genus of Tooth-Billed Birds (*Dentirostres*). Cuvier places the genus among the Dentirostral genera of his second order *Passereaux*; Latreille also arranges it under that order, but does not allow it to belong to the *Dentirostres*, and classes it among his first family, that of the Broad-Billed Birds (*Latirostres*). Temminck, considering it to be an omnivorous bird, finds a place for it under the name of *Bombycivora*, in his second order *Omnivores*. Vieillot's second order (*Sylvicolæ*) contains two tribes; and in the sixteenth family (*Baccivori*) of the second tribe (*Anisodactyli*), the genus in question will be found. Vigors places it in the second tribe *Dentirostres* of his second order, *Insessores*, or Perching Birds; and after some hesitation, and expressing his doubt whether its natural situation is not in the family *Merulidæ*, is inclined to arrange it provisionally among the *Pipridæ*, his last family of *Dentirostres*. Bonaparte makes it a genus of his family *Sericati*. Swainson, in the 'Fauna Boreali-Americana,' arranges it under his *Bombycillinæ*, a subfamily belonging to the aberrant group of his *Ampelidæ*, or Fruit-Eaters; but in giving his table of *Ampelidæ*, he expresses considerable doubts on the true nature of the aberrant divisions. Linnæus at one time made it a Butcher-Bird (*Lanius*), and afterwards an *Ampelis*. Brisson classed it among the Thrushes (*Turdus*), and Illiger among the Crows (*Corvus*).

The birds of this genus are known by the English names of Wax-Wings or Waxen-Chatterers; and the following are the principal generic characters according to Temminck:—Bill short, straight, elevated; upper mandible curved towards its extremity, with a strongly marked tooth; nostrils basal, ovoid, open, hidden by strong hairs directed forwards; feet, with three toes before and one behind, the exterior toe connected (soudé) with the middle one; wings moderate, the first and second quills longest.

Only three species have been recorded. The first has a wide geographical range; the second is confined to North America; and the third is Oriental.

B. garrula, European Wax-Wing or Chatterer. This elegant species, which is also known by the English names of the Bohemian Chatterer, Bohemian Wax-Wing and Silk-Tail, is Le Jaseur de Bohême (Buffon, &c.), Grand Jaseur (Temminck), and Geay de Bohême of the French; Garrulo di Boemia of the Italians; Rothlichgrauer Seidenschwantz (Meyer), Europäischer Seidenschwanz, and Gemeine Seidenschwanz (Bechstein) of the Germans; *Garrulus Bohemicus* of Gesner; *Bombycilla* of Schwenck.; *Ampelis* of Aldrovand.; *Bombycilla Bohemica* of Brisson; *Ampelis garrulus* of Linnæus; *Bombyciphora garrula* of Brehm; *Bombyciphora poliocælia* of Meyer; *Bombycivora garrula* of Temminck; and *Bombycilla garrula* of Vieillot.

In addition to the nomenclature above given, the bird is said to be named by the Italians in some localities Becco-Frisone, in others, Galletto del Bosco; and by the bird-catchers of Bologna, Uccello del Mondo Novo; by the Germans, Zinzerelle, Wipstertz, Schnee-Vogel and Schnee-Leschke, and by those in the neighbourhood of Nürnberg, Beemerle and Behemle; by the Swedes, Siden-Swantz; and by the Bohemians, Brkoslaw.

That the Bohemian Chatterer was known to the ancients there can be little doubt; but a great deal of obscurity prevails as to the names by which it was distinguished. Some have taken it to be the *Incendiaria Avis* of Pliny (book x. c. 13), the inauspicious bird, on account of whose appearance Rome more than once underwent lustration, but more especially in the consulship of L. Cassius and C. Marius, when the apparition of a great owl (*Bubo*) was added to the horrors of the year. Others have supposed that it was the bird of the Hercynian forest (book x. c. 47), whose feathers shone in the night like fire. Aldrovandus, who collected the opinions on this point, has taken some pains to show that it could be neither the one nor the other. The worthy Italian gravely assures his readers that its feathers do not shine in the night; for he says he kept one alive for three months, and observed it at all hours ("quâvis noctis horâ contemplatus sum").

It is by no means improbable that this bird was the *Γνάφαλος* of Aristotle ('Hist. Anim.,' book ix. c. 16).

The geographical range of the Bohemian Chatterer is extensive, comprehending a great portion of the arctic world. It appears generally in flocks, and a fatality was at one time believed to accompany their movements. Thus Aldrovandus observes that large flights of them appeared in February, 1530, when Charles V. was crowned at Bologna; and again in 1551, when they spread through the duchies of Modena, Piacenza, and other Italian districts, carefully avoiding that of Ferrara, which was afterwards convulsed by an earthquake. In 1552, according to Gesner, they visited the banks of the Rhine, near Mentz, in such myriads that they darkened the air. In 1571 troops of them were seen flying about the north of Italy, in the month of December, when the Ferrarese earthquake, according to Aldrovandus, took place, and the rivers overflowed their banks.

Necker, in his Memoir on the Birds of Geneva, observes that from the beginning of this century only two considerable flights have been observed in that canton, one in January, 1807, and the other in 1814, when they were very numerous, and having spent the winter there, took their departure in March. In the first of those years they were scattered over a considerable part of Europe, and early in January were seen near Edinburgh. Savi observes that they are not seen in Tuscany except in very severe winters, and that the years 1806 and 1807 were remarkable for the number of them which entered Piedmont, especially the valleys of Lanzo and Suza.

It has been said that it is always rare in France, and that of late years it has become scarce in Italy and Germany; but Bechstein observes that in moderate seasons it is found in great flights in the skirts of the forests throughout the greater part of Germany and Bohemia, and that it is to be seen in Thuringia only in the winter: if the season be mild in very small numbers, the greater portion remaining in the north; if the weather be severe, it advances farther south.

The Bohemian Chatterer must be considered only as an occasional visitant to the British Islands, though Pennant says that they appear only by accident in South Britain, but that about Edinburgh they come annually in February, and feed on the berries of the mountain-ash; adding that they also appear as far south as Northumberland, and like the fieldfare make the berries of the white thorn their food: he records the death of one which was killed at Garthmeilio in Denbighshire in a fir-tree during the severe frost of December, 1788. Latham, in a note to this statement, says that the late Mr. Tunstall informed him that in the winter of 1787 many flocks were seen all over the county of York, and that towards the spring a flock of between twenty and thirty were observed within two miles of Wycliffe, his place of residence. Bewick states that in the years 1790, 1791, and 1803 several of them were taken in Northumberland and Durham as early as the month of November. Selby says that in the winter of 1810 large flocks were dispersed through various parts of the kingdom, and that from that period it does not seem to have visited our island till the month of February, 1822, when a few came under his inspection, and several were again observed during the severe storm in the winter of 1823. Montagu says that he received it out of Staffordshire, and that he has known others killed in the more southern counties in the autumn and winter. In Mr. Rennie's edition of the 'Ornithological Dictionary' (1833) it appears that one had been shot in the park of Lord Boringdon at Saltram in Devonshire, and that not less than twenty have been killed in the counties of Suffolk and Norfolk during the last three winters. Graves says that about Christmas, 1803, a number were shot in the neighbourhood of Camberwell, from one of which, being but slightly wounded, his figure was taken. In 'Loudon's Magazine' it is stated that a fine specimen was shot near Coventry in December, 1830, where it appeared to associate with starlings, and that during the same month of the same year six were killed in the vicinity of Ipswich. The late Mr. W. Thompson records various instances of the occurrence of this bird in Ireland. In the British Islands it more frequently occurs in the north than the south, and Mr. Yarrell states that "the winters of 1787, 1788, 1789, 1790, 1791, 1803, 1810, 1820, 1822, 1828, 1830, 1831, 1834, and 1835, are particularly recorded as having afforded opportunities of obtaining specimens in some one or other of various northern localities."

Although called the Bohemian Wax-Wing, it is not more common in Bohemia than England. In the central and southern parts of the European continent it is only an occasional visitor.

In northern Russia and the extreme north of Norway, according to C. L. Bonaparte, they are seen in great numbers every winter, being observed there earlier than in temperate countries. In northern Asia and eastern Europe their migrations are tolerably regular. Very numerous flocks pass through Scania in November, and are again seen on their return in the spring.

But the species is not confined to Europe and Asia. "By a singular coincidence," says the Prince of Canino, "whilst we were proclaiming this species as American, it was received by Temminck from Japan, together with a new species, the third known of the genus." He says that his best specimen was shot on the 20th of March, 1825, on the Athabasca River, near the Rocky Mountains; and observes that the species appears to be spread widely, as he had been credibly informed by hunters that "cedar-birds of a large kind" had been shot a little beyond the Mississippi; adding that he is at a loss to conceive why it should never have been observed on this side of the last-mentioned river. Mr. Drummond in the spring of 1826 saw it near the sources of the Athabasca, and Sir John Richardson observed it in the same season at Great Bear Lake in lat. 65°, where a male, of which he gives a description, was shot on the 24th of May of that year. He also says that he observed a large flock of at least three or four hundred on the banks of the Saskatchewan, at Carlton House, early in May, 1827. They alighted in a grove of poplars, settling all on one or two trees, and making a loud twittering noise. They stayed only about an hour in the morning, and were too shy to allow him to approach within gunshot.

The district where these birds breed is unknown. Bechstein says that it does not build in Germany when wild, but within the Arctic Circle.

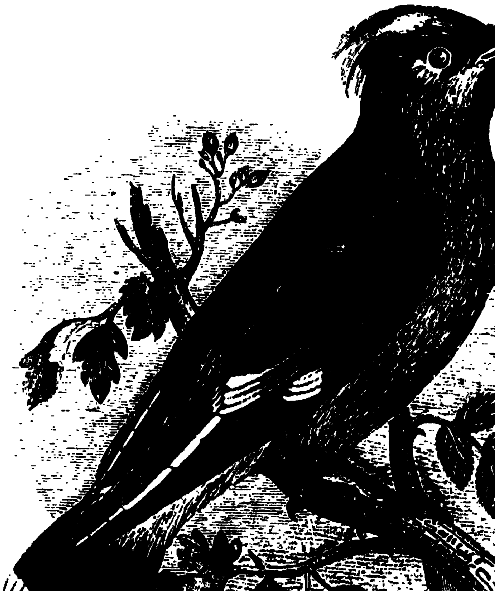
Bonaparte gives a very amiable character of the European Wax-Wing in a state of nature, attributing to them a particular sentiment of benevolence, even independent of reciprocal sexual attraction. "Not only," says the Prince, "do the male and female caress and feed each other, but the same proofs of mutual kindness have been observed between individuals of the same sex." Speaking of their habits he says, "They always alight on trees, hopping awkwardly on the ground. Their flight is very rapid: when taking wing they utter a note resembling the syllables zi, zi, ri, but are generally silent notwithstanding the name that has been given them." Bechstein says, "When wild we see it in the spring eating, like thrushes, all sorts of flies and other insects; in autumn and winter, different kinds of berries; and in time of need, the buds and sprouts of the beech, maple, and various fruit-trees." Willughby states that it feeds upon fruit, especially grapes, of which it is very greedy. "Wherefore it seems to me," he adds, "not without reason, to be called by that name *Ampelis*." Bonaparte makes their food to consist of different kinds of juicy berries, or of insects, observing that they are fond of the berries of the mountain-ash and *Phytolacca*, and that they are extremely greedy of grapes, and also, though in a less degree, of juniper- and laurel-berries, apples, currants, figs, and other fruits. He adds that they drink often, dipping their bills repeatedly.

In captivity its qualities do not appear to be very attractive, according to Bechstein, who says that nothing but its beauty and scarcity can render the possession of it desirable, for that it is a stupid and lazy bird. Indeed he draws such a picture of its greediness and dirty habits, that, if it be not overcharged, few we should think would wish to have it as an inmate. Leaving out the more unpleasant parts of his description, we take the following extract from his 'Cage Birds':—"During the ten or twelve years that it can exist in confinement, and on very meagre food, it does nothing but eat and repose for digestion. If hunger induces it to move, its step is awkward, and its jumps so clumsy as to be disagreeable to the eye. Its song consists only of weak and uncertain whistling, a little resembling the thrush, but not so loud. While singing it moves the crest, but hardly moves the throat. If this warbling is somewhat unmusical it has the merit of continuing throughout every season of the year. When angry, which happens sometimes near the common feeding-trough, it knocks very violently with its beak. It is easily tamed." The same author says, that in confinement the two universal pastes appear delicacies to it; and it is even satisfied with bran steeped in water. It swallows everything voraciously, and refuses nothing eatable, such as potatoes, cabbage, salad, fruit of all sorts, and especially white bread. It likes to bathe, or rather to sprinkle itself with water, for it does not wet itself so much as other birds.

It is taken in nooses, to which berries are fixed, which for this purpose, says the author last quoted, "should always be kept in store till February. It appears to be frightened at nothing, for it flies into nets and traps, though it sees its companions caught, and hanging and uttering cries of distress and fear."

Length about eight inches; the size altogether approaching that of a starling.

Male. Bill strong, black, except at the base, where the colour inclines to a yellowish-white; nostrils hidden under small black feathers. Irides purplish-red. Chin and throat velvety black, as is also the streak (in the midst of which is the eye) passing from the bill to the hinder part of the head. Forehead reddish-brown. Head feathers long, silky, forming a reclining crest approaching to reddish-chestnut, which the bird can erect or depress at pleasure. Upper parts purplish-red, or vinaceous-brown dashed with ash-colour, the rump lightest. Breast and belly pale purplish-ash, tinged with pale brownish-red. Vent and under tail-coverts orange-brown inclining to reddish-orange. Greater wing-coverts black, tipped with white. Lesser wing-coverts of a shade darker than the general tint of the upper plumage. Primaries black, with a bright yellow spot near the white tips of their outer webs. Montagu says that the three first are tipped with white, and the others with yellow on their outer margins. Secondaries gray, tipped with white on the outer web, and seven or eight of them terminated with small flattish, oval, horny appendages, of the colour of red sealing-wax. Sometimes there are not more than 5 or 6 of these wax-like tips, and in Montagu's specimen there were 5 on one side and 6 on the other. Graves gives the number at from 6 to 9 (Bechstein at from 5 to 9), and mentions the specimen in Mr. Haworth's collection, which had some on the tail, which is black tipped with yellow, and dashed with ash-colour at the base. Shanks, toes, and claws, black.



European Wax-Wing (*Bombycilla garrula*), male.

Female. Generally similar to the male; but the yellow on the wings and tail is not so bright, nor are the wax-like appendages so large or so numerous.

The flesh of this species is said to be delicate food.

B. Carolinensis, the American Wax-Wing, or Cedar-Bird, was considered by some of the older naturalists to be identical with the European species, from which it had degenerated.

This species is the *Ampelis garrulus*, var. β. of the 'Systema Naturæ'; *Garrulus Carolinensis*, le Jaseur de Caroline, the Chatterer of Catesby; *Turdus garrulus Carolinensis* of Klein; Coquantotot of Hernandez; *Avis Americana cristata, Xomotl dicta* of Seba; Chatterer of Carolina of Edwards; Cedar-Bird, *Ampelis Americana*, of Wilson; Recollet of the Canadian Voyageurs; *Bombycilla Carolinensis* of Brisson, Bonaparte, Audubon, and others. It is said to be found in the whole extent between Mexico and Canada, and parties are said occasionally to roam as far south as the forests of Guyana. In the United States it is a resident during the whole year, the northern and middle states being its more usual quarters in the summer, and the southern in the winter season. It is stated that the bird has been found on the north-west coast of America, but its northern boundary appears to fall short of that of *Bombycilla Bohemica.* Say saw it near the Winnipeg River, in lat. 50°, and Sir John Richardson states his belief that it has not been hitherto observed to the northward of the 54th parallel. He says that Mr. Drummond saw several small flocks on the south branch of the Saskatchewan on the 27th June, and gives a description of a male killed there in lat. 52½° on that day, 1827. He adds that it frequents the northern shores of Lake Huron and of Lake Superior in summer.

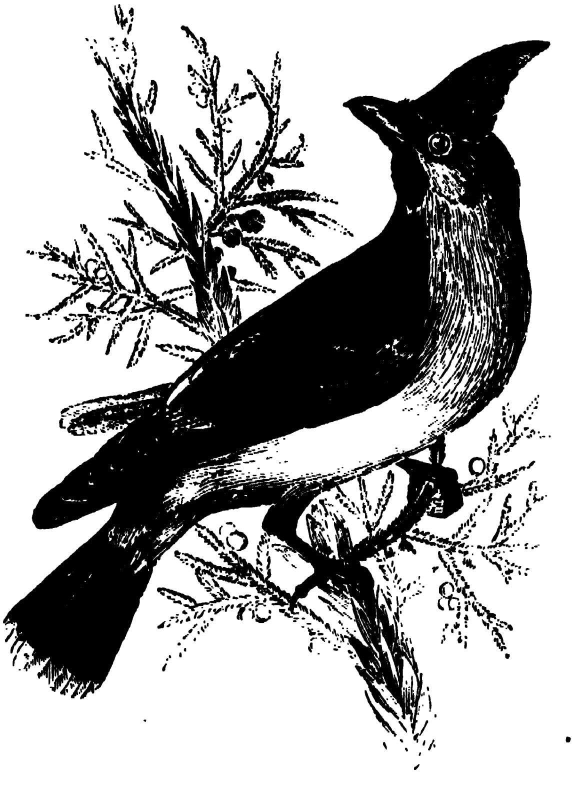
The Cedar-Birds utter a feeble lisping sound, and fly, says Wilson, "in compact bodies of from twenty to fifty; and usually alight so close together on the same tree, that one half are frequently shot down at a time. In the months of July and August they collect together in flocks, and retire to the hilly parts of the state, the Blue Mountains, and other collateral ridges of the Alleghany, to enjoy the fruit of the *Vaccinium uliginosum*, Whortleberries, which grow there in great abundance, whole mountains for many miles being almost entirely covered with them; and where in the month of August I have myself found the cedar-birds numerous. In October they descend to the lower cultivated parts of the country, to feed on the berries of the sour gum and red cedar, of which last they are immoderately fond; and thirty or forty may sometimes be seen fluttering among the branches of one small cedar-tree, plucking off the berries. . . . . In the fall and beginning of summer, when they become very fat, they are in considerable esteem for the table; and great numbers are brought to the market of Philadelphia, where they are sold at from twelve to twenty-five cents per dozen. During the whole winter and spring they are occasionally seen; and about the 25th of May appear in numerous parties, making great havoc among the early cherries, selecting the best and ripest of the fruit." Audubon says that they reach Louisiana about the beginning of November, and retire towards the middle districts in the beginning of March. "The holly," writes the author last quoted, "the vines, the persimon, the pride of China, and various other trees, supply them with plenty of berries and fruits, on which they fatten, and become so tender and juicy as to be sought by every epicure for the table. I have known an instance of a basketful of these little birds having been forwarded to New Orleans as a Christmas present." And delicious these fruit-eating birds (for such is their general diet, albeit they are said to be excellent fly-catchers) undoubtedly are; though Hernandez, who met with them near Tetzeuco (apud Tetzcoquenses), says that neither in their song nor in the flavour of their flesh are they better than other small birds ("neque est cantu aut nutrimento cæteris aviculis commendatior"). Their appetite is extraordinary: "They gorge themselves," observes Audubon, "to such excess, as sometimes to be unable to fly, and suffer themselves to be taken by the hand. Indeed I have seen some which, although wounded and confined in a cage, have eaten of apples until suffocation deprived them of life in the course of a few days. When opened afterwards they were found to be gorged to the mouth."

Notwithstanding this greediness they are, according to some writers, remarkable for their social and kindly disposition in a state of nature. Nuttall, on the authority of an eye-witness, states that one among a row of these birds seated upon a branch, darted after an insect, and offered it to his associate when caught, who very disinterestedly passed it to the next, and each delicately declining the offer, the morsel went backwards and forwards before it was appropriated.

After fattening on the fruits of May and early June they begin to turn their attention to the continuation of their species, and commence about the 10th or 12th of the latter month building a nest large in proportion to the bird, sometimes in their favourite cedar-tree (*Juniperus Virginiana*, Willd.), but more frequently in the orchards, generally choosing a forked or horizontal branch of an apple-tree, some ten or twelve feet from the ground. Outwardly and at the bottom is laid a mass of coarse dry stalks of grass; the inside is lined entirely with very fine stalks of the same material. The eggs are three or four, of a dingy bluish-white, thick at the great end, tapering suddenly, and becoming very narrow at the other, marked with small roundish spots of black of various sizes and shades; and the great end is of a pale dull purple tinge, marked likewise with touches of various shades of purple and black. About the last week in June the young are hatched, and are at first fed on insects and their larvæ, but as they advance in growth on berries of various kinds.

The following is Nuttall's account of the manners of this bird in captivity:—

"A young bird from one of the nests described in the hemlock was thrown upon my protection, having been by some means ejected from his cradle. In this critical situation however he had been well fed or rather gorged with berries, and was merely scratched by the fall he had received. Fed on cherries and mulberries he was soon well fledged, while his mate in the nest was suffered to perish by the forgetfulness of his natural protectors. Coeval with the growth of his wing-feathers were already seen the remarkable red waxen appendages, showing that their appearance indicates no particular age or sex; many birds, in fact, being without these ornaments during their whole lives. I soon found my interesting protégé impatient of the cage, and extremely voracious, gorging himself to the very mouth with the soft fruits on which he was often fed. The throat, in fact, like a craw admits of distension, and the contents are only gradually passed off into the stomach. I now suffered the bird to fly at large, and for several days he descended from the trees in which he perched to my arm for food; but the moment he was satisfied he avoided the cage, and appeared by his restlessness unable to survive the loss of liberty. He now came seldomer to me, and finally joined the lisping muster-cry of 'tze, tze, tzó,' and was enticed away after two or three attempts by his more attractive and suitable associates. When young, nature provided him with a loud impatient voice, and 'té-did, té-did, kai-té-did' (often also the clamorous cry of the young Baltimore) was his deafening and almost incessant call for food. Another young bird of the first brood, probably neglected, cried so loud and plaintively to a male Baltimore bred in the same tree, that he commenced feeding it. Mr. Winship of Brighton informs me that one of the young Cedar-Birds which frequented the front of his house in quest of honeysuckle-berries, at length on receiving food, probably also abandoned by his roving parents, threw himself wholly on his protection. At large day and night, he still regularly attended the dessert of the dinner-table for his portion of fruit, and remained steadfast in his attachment to Mr. Winship till killed by an accident, being unfortunately trodden under foot."

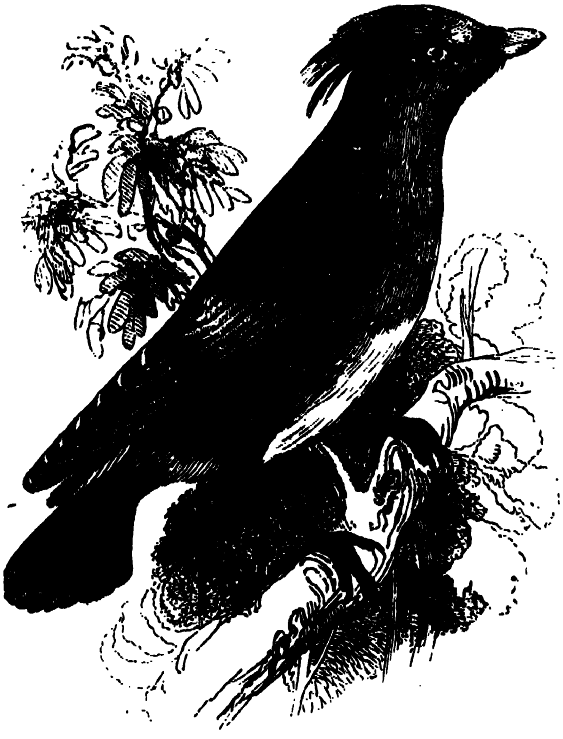


American Wax-Wing (*Bombycilla Carolinensis*), male.

The following is Wilson's description:—"Length seven inches, extent eleven inches; head, neck, breast, upper part of the back and wing-coverts, a dark fawn colour, darkest on the back and brightest on the front; head ornamented with a high, pointed, almost upright crest; line from the nostril over the eye to the hind head velvety black, bordered above with a fine line of white, and another line of white passes from the lower mandible; chin black, gradually brightening into fawn-colour, the feathers there lying extremely close; bill black, upper mandible nearly triangular at the base, without bristles, short, rounding at the point, where it is deeply notched; the lower scolloped at the tip, and turning up; tongue as in the rest of the genus, broad, thin, cartilaginous, and lacerated at the end; belly yellow; vent white; wings deep slate, except the two secondaries next the body, whose exterior vanes are of a fawn-colour, and interior ones white, forming two whitish strips there, which are very conspicuous; rump and tail-coverts pale light blue; tail the same, gradually deepening into black, and tipped for half an inch with rich yellow. Six or seven and sometimes the whole nine secondary feathers of the wings are ornamented at the tips with small red oblong appendages, resembling red sealing-wax; these appear to be a prolongation of the shafts, and to be intended for preserving the ends and consequently the vanes of the quills from being broken and worn away by the almost continual fluttering of the bird among the thick branches of the cedar. The feathers of those birds which are without these appendages are uniformly found ragged on the edges, but smooth and perfect in those on whom the marks are full and numerous. These singular marks have been considered as belonging to the male alone, from the circumstance perhaps of finding female birds without them. They are however common to both male and female. Six of the latter are now lying before me, each with large and numerous clusters of eggs, and having the waxen appendages in full perfection. The young birds do not receive them until the second fall, when in moulting time they may be seen fully formed, as the feather is developed from its sheath. I have once or twice found a solitary one on the extremity of one of the tail-feathers. The eye is of a dark blood-colour; the legs and claws black; the inside of the mouth orange; gape wide; and the gullet capable of such distension as often to contain twelve or fifteen cedar-berries, and serving as a kind of craw to prepare them for digestion. The chief difference in the plumage of the male and female consists in the dulness of the tints of the latter, the inferior appearance of the crest, and the narrowness of the yellow bar at the tip of the tail."

B. phœnicoptera, the Asiatic Wax-Wing. The discovery of the Red-Winged Chatterer, or Japanese Wax-Wing, is one of the fruits of Dr. Siebold's scientific mission to Japan by the government of the Netherlands. In size it bears a greater resemblance to the Cedar-Bird than to the Bohemian Wax-Wing, but differs from both in the nakedness of the nostrils (which are not hidden by the small feathers of the front, like the nostrils of the other two species of this small but natural group), in the length of the crest, and the beautiful black plumes with which it is ornamented, and by the entire absence of the wax-like appendages that tip the secondaries of its congeners.

The length of the Japanese Wax-Wing is six inches and six lines. The base of the bill is bordered by a black band, which passes to the back of the head, surrounding the eye in its way, and terminates in the lower crest-feathers, which are of the same colour throughout; the chin and throat are black; the crest is long, composed above of feathers of an ashy-reddish colour with an inferior layer of the black plumes already alluded to; the breast, upper parts, and wing-coverts are of a brownish-ash, and a red band traverses the wing about the middle of it; all the quills are of an ashy-black, the greater quills terminated with black and tipped with white; the tail is of an ashy-black, tipped with vivid red; the middle of the belly is of a whitish-yellow; and the lower tail-coverts chestnut; shanks and feet black.



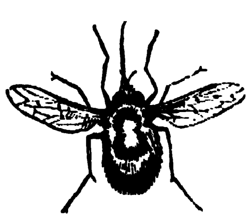
Asiatic Wax-Wing (*Bombycilla phœnicoptera*), male.

The species is found in the neighbourhood of Nangasaki.

Temminck, to whom we are indebted for our knowledge of the bird, which is described and figured in his 'Planches Coloriées,' says that there is a specimen in the galleries of the museum of the Pays-Bas, and another in the collection of M. Blomhof, the resident at Japan; and he observes that the absence of the nostril-plumes furnishes a proof, also afforded in the genera *Corvus* and *Garrula*, in contradiction to the opinion of those systematists who would separate the omnivorous birds with covered nostrils from those which have those organs smooth or naked, and divide them into distinct groups. He also considers the proper position of the genus to be near the *Pirolles* (Kitta), and the *Rolles* (*Colaris* of Cuvier, *Eurystomus* of Vieillot).

BOMBY'LIDÆ, a family of Insects of the order *Diptera*, distinguished chiefly by having a long proboscis. The body is short and very hairy. Antennæ moderate, four-jointed, the basal joint long, second very short, third longest, the apical joint minute and tapering to a fine point. The legs are long and very slender. Wings horizontal.

The species of this tribe are all remarkable for their great swiftness of flight; two species of the genus *Bombylius* are not uncommon in open parts of woods, frequenting sunny banks, where they may be seen, in the month of April, hovering over flowers, from which they sip the sweets by means of their long proboscis, which enables them to do this without settling on the flowers.



Bombylius medius.

At one time they will be seen apparently quite motionless in the air—for their wings vibrate so rapidly that they cannot be discerned—a moment after they will make their appearance at a few yards' distance, having darted from one spot to the other with such rapidity that the eye cannot follow them. In their flight they emit a humming sound.

The two species here spoken of are *B. major* and *B. medius;* they are about one-third of an inch long and of a brown colour; the former has the anterior part of its wings clouded with an opaque brown colour, and the posterior part transparent—the latter has the wings adorned with numerous brown spots, and their anterior portion but slightly clouded.

Mr. Stephens enumerates seven species of this genus as indigenous to this country; they are sometimes called Humble-Bee Flies.

BOMBYX. [BOMBYCIDÆ.]

BONA'SIA, a genus of Birds belonging to the *Tetraonidæ* (Grouse Family). It is thus characterised by C. L. Bonaparte:—

Lower portion of the tarsus or shank and the toes naked; tail long and rounded; the head adorned with a crest, and the sides of the neck with a ruff. The plumage of the female nearly the same as that of the male, and varying but little throughout the year.

Swainson retains the Linnæan name for the bird, and makes *Tetrao* the typical group of the subgenera into which he divides the genus, expressing however considerable doubt on the value of the types.

The Ruffed Grouse (*Bonasia Umbellus* of Bonaparte; *Tetrao Umbellus* and *Tetrao togatus* of Linnæus; *Tetrao Umbellus* of Linnæus and Swainson) is the Shoulder-Knot Grouse of Latham; the Ruffed Heathcock or Grouse of Edwards; La Gelinote Hupée de Pensilvanie of Brisson; La Grosse Gelinotte de Canada and Le Coq de Bruyère à Fraise of Buffon; the Pheasant of the Pennsylvanians, and of the inhabitants of the southern States; the White Flesher and Pheasant of the Anglo-Americans generally.

Audubon says that to the west of the Alleghanics, and on those mountains, the term Pheasant is generally used to designate the bird, and that the same appellation is employed in the middle States to the east of the mountains, till the State of Connecticut is entered, where the name of Partridge prevails. Lawson uses the term Pheasant. "The pheasant of Carolina differs some small matter from the English pheasant, being not so big, and having some difference in feather; yet he is not any wise inferior in delicacy, but is as good meat or rather finer. He haunts the back-woods, and is seldom found near the inhabitants." Wilson calls it throughout Pheasant, except in one place, where he terms it the Pheasant or Partridge of New England.

According to the author last quoted, this bird is known in almost every quarter of the United States; is common at Moose Fort, on Hudson's Bay, in lat. 51°; frequent in the upper part of Georgia, and very abundant in Kentucky and Indiana. In the lower parts of Carolina, Georgia, and Florida, according to the same authority, it is very seldom observed, but on advancing inland to the mountains it again makes its appearance; and though it is occasionally met with in the lower parts of New Jersey, its occurrence there is considered to be owing to the more northerly situation of the country; for even here they are far less numerous than among the mountains.

Captains Lewis and Clarke found it in crossing the Rocky Mountains which divide the basin of the Columbia from that of the Mississippi, more than 3000 miles by their measurement from the mouth of the latter river. Sir John Richardson says that it exists as far north as the 56th parallel, and that it is very plentiful on the banks of the Saskatchewan; adding in a note, that Mr. Drummond procured specimens at the sources of the Peace River, in the valleys of the Rocky Mountains, which do not differ from those killed on the Saskatchewan. The limit of its southern range has been stated to be the Gulf of Mexico. Audubon found these birds most numerous in the States of Pennsylvania and new York, and says that they are to be met with as you travel towards the south, through the whole of Tennessee and the Choctaw territory; but that as you approach the city of Natchez they disappear; nor had he ever heard of one of these birds having been seen in the State of Louisiana.

"The manners of the pheasant," says, Wilson, "are solitary; they are seldom found in coveys of more than four or five together, and more usually in pairs or singly. They leave their sequestered haunts in the woods early in the morning, and seek the path or road to pick up gravel, and glean among the droppings of the horses. In travelling among the mountains that bound Susquehanna, I was always able to furnish myself with an abundant supply of these birds every morning without leaving the path. If the weather be foggy or lowering, they are sure to be seen in such situations. They generally move along with great stateliness, with their broad fan-like tail spread out."

Audubon states that, although they are attached to the craggy sides of mountains and hills, and rocky borders of small streams thickly mantled with evergreen trees and shrubs, they at times remove to the lowlands, and even enter the thickest cane-brakes, where they sometimes breed, and where he shot some, and heard them drumming when there were no hills nearer than 15 or 20 miles. The lower parts of the State of Indiana, and also those of Kentucky, were amongst the places where he so discovered them. The following is his account of their autumnal migrations, which he seems to have first observed:—

"The ruffed grouse although a constant resident in the districts which it frequents, performs partial sorties at the approach of autumn. These are not equal in extent to the peregrinations of the wild turkey, our little partridge, or the pinnated grouse, but are sufficiently so to become observable during the seasons when certain portions of the mountainous districts which they inhabit become less abundantly supplied with food than others. These partial movings might not be noticed, were not the birds obliged to fly across rivers of great breadth, as whilst in the mountain lands their groups are as numerous as those which attempt these migrations; but on the north-west banks of the Ohio and Susquehanna rivers, no one who pays the least attention to the manners and habits of our birds can fail to observe them. The grouse approach the banks of the Ohio in parties of eight or ten, now and then of twelve or fifteen, and on arriving there linger in the woods close by for a week or a fortnight, as if fearful of encountering the danger to be incurred in crossing the stream. This usually happens in the beginning of October, when these birds are in the very best order for the table, and at this period great numbers of them are killed. If started from the ground, with or without the assistance of a dog, they immediately alight on the nearest trees, and are easily shot. At length however they resolve upon crossing the river; and this they accomplish with so much ease that I never saw any of them drop into the water. Not more than two or three days elapse after they have reached the opposite shore, when they at once proceed to the interior of the forests in search of places congenial to the general character of their habits. They now resume their ordinary manner of living, which they continue until the approach of spring, when the males, as if leading the way, proceed singly towards the country from which they had retreated. The females follow in small parties of three or four. In the month of October, 1820, I observed a larger number of ruffed grouse migrating thus from the states of Ohio, Illinois, and Indiana into Kentucky, than I had ever before remarked. During the short period of their lingering along the north-west shore of the Ohio that season, a great number of them was killed, and they were sold in the Cincinnati market for so small a sum as 12½ cents each."

Wilson says that the Ruffed Grouse is in the best order for the table in September and October. At this season they feed chiefly on whortleberries, and the little red aromatic Partridge-Berries (*Gaultheria procumbens*), the last of which give their flesh a peculiarly delicate flavour. With the former the mountains are literally covered from August to November; and these constitute at that season the greater part of their food. During the deep snows of winter they have recourse to the buds of alder, and the tender buds of the laurel (*Kalmia*). He frequently found their crops distended with a large handful of these latter alone; and adds, that it has been confidently asserted, that after having fed for some time on the laurel-buds, their flesh becomes highly dangerous to eat of, partaking of the poisonous qualities of the plant. The same has been asserted of the flesh of the deer, when in severe weather and deep snows they subsist on the leaves and bark of the laurel. "Though," continues Wilson, "I have myself eat freely of the flesh of the pheasant after emptying it of large quantities of laurel buds, without experiencing any bad consequences, yet from the respectability of those, some of them eminent physicians, who have particularised cases in which it has proved deleterious, and even fatal, I am inclined to believe that in certain cases where this kind of food has been long continued, and the birds allowed to remain undrawn for several days, until the contents of the crop and stomach have had time to diffuse themselves through the flesh, as is too often the case, it may be unwholesome and dangerous. Great numbers of these birds are brought to our markets at all times during fall and winter, some of which are brought from a distance of more than a hundred miles, and have been probably dead a week or two, unpicked and undrawn, before they are purchased for the table. Regulations prohibiting them from being brought to market unless picked and drawn would very probably be a sufficient security from all danger. At these inclement seasons however they are generally lean and dry, and indeed at all times their flesh is far inferior to that of the quail or of the pinnated grouse. They are usually sold in Philadelphia market at from three-quarters of a dollar to a dollar and a quarter a pair, and sometimes higher."

Audubon observes that they are brought to the market in great numbers during the winter months, and sell at from 75 cents to a dollar a-piece in the eastern cities. At Pittsburg he bought them some years ago at 12½ cents the pair. Nuttall says, when he wrote, that they were greatly thinned throughout the more populous parts of the Union, and that they sold in Philadelphia and New York at from 75 cents to a dollar a-piece.

The food of the Ruffed Grouse consists commonly in the spring and fall, according to the author last quoted, of the buds of trees, the catkins of the hazel and alder, even fern-buds, acorns, and seeds of various kinds, among which he detected the capsules, including the seeds, of the common small Canadian Cistus (*Helianthemum*). At times he has seen the crop almost entirely filled with the buds of the apple-tree, each connected with a portion of the twig, the wood of which appears to remain a good while undigested; cinquefoil and strawberry leaves, buds of the Azaleas and of the broad-leaved Kalmia, with the favourite Partridge-Berries (*Gaultheria procumbens*), Ivy-Berries (*Cissus hederacea*), and gravel pebbles, are also some of the many articles which form the winter fare of the bird. In summer they seem often to prefer berries of various kinds, particularly dew-berries, strawberries, grapes, and whortleberries.

We will now lay before the reader the modes of capturing the bird. The following is Wilson's account:—

"The pheasant generally springs within a few yards, with a loud whirring noise, and flies with great vigour through the woods beyond reach of view, before it alights. With a good dog however they are easily found; and at some times exhibit a singular degree of infatuation, by looking down from the branches where they sit on the dog below, who, the more noise he keeps up, seems the more to confuse and stupify them, so that they may be shot down one by one till the whole are killed, without attempting to fly off. In such cases those on the lower limbs must be taken first, for should the upper ones be first killed, in their fall they alarm those below, who immediately fly off. In deep snows they are usually taken in traps, commonly dead traps, supported by a figure 4 trigger. At this season when suddenly alarmed, they frequently dive into the snow, particularly when it is newly fallen, and coming out at a considerable distance, again take wing. They are pretty hard to kill, and will often carry off a large load to the distance of two hundred yards and drop down dead. Sometimes in the depth of winter they approach the farm-house and lurk near the barn, or about the garden. They have also been often taken young and tamed, so as to associate with fowls; and their eggs have frequently been hatched under the common hen; but these rarely survive until full grown. They are exceedingly fond of the seeds of grapes; occasionally eat ants, chestnuts, blackberries, and various vegetables. Formerly they were numerous in the immediate vicinity of Philadelphia; but as the woods were cleared and population increased they retreated to the interior. At present (1812) there are very few to be found within several miles of the city, and those only singly, in the most solitary and retired woody recesses."

Audubon denies that they are ever so easily shot as stated above.

The pairing time of these birds is marked by a curious and sonorous act on the part of the male. Most of the grouse family gesticulate considerably at this period, and some produce very peculiar vocal noises; but the Ruffed Grouse makes the woods echo with the vibrations of his wings. The following is Audubon's account of this fact:—

"Early in April the ruffed grouse begins to drum immediately after dawn, and again towards the close of the day. As the season advances, the drumming is repeated more frequently at all hours of the day; and where these birds are abundant this curious sound is heard from all parts of the woods in which they reside. The drumming is performed in the following manner:—The male bird, standing erect on a prostrate decayed trunk, raises the feathers of its body in the manner of a turkey-cock, draws its head towards its tail, erecting the feathers of the latter at the same time, and raising its ruff around the neck, suffers its wings to droop, and struts about on the log. A few moments elapse, when the bird draws the whole of its feathers close to its body, and stretching itself out, beats its sides with its wings, in the manner of the domestic cock, but more loudly, and with such rapidity of motion after a few of the first strokes, as to cause a tremor in the air not unlike the rumbling of distant thunder. In perfectly calm weather it may be heard at the distance of two hundred yards, but might be supposed to proceed from a much greater distance. The female, which never drums, flies directly to the place where the male is thus engaged, and on approaching him, opens her wings before him, balances her body to the right and left, and then receives his caresses. . . . I have shot many a fine cock by imitating the sound of its own wings striking against the body, which I did by beating a large inflated bullock's bladder with a stick, keeping up as much as possible the same time as that in which the bird beats. At the sound produced by the bladder and the stick, the male grouse, inflamed with jealousy, has flown directly towards me, when being prepared I have easily shot it."

The pairing time in April is succeeded by the nidification in the early part of May. The root of a bush, the side of a fallen log, or some other sheltered nook in the thickest part of the woods, is selected by the hen, and there she forms a rude nest of withered leaves and grass on the ground. The eggs, from nine to fifteen in number, are of a uniform dull yellowish colour, or brownish-white, and are nearly as large as those of a pullet. As soon as the young are out of the shell they begin to run about, and are conducted by the mother, clucking as she goes, very much like the domestic hen. Like her too at night and in bad weather she covers her young ones beneath her wings, and in a week or ten days they begin to try their powers of flight. Her manœuvres to decoy the intruder from the spot where her young are concealed, by counterfeiting lameness and by mimicry of distress, are well known.

The Ruffed Grouse is surrounded by enemies. In addition to the common persecutor, man, the different species of hawks are on the watch for these birds, and particularly the red-tailed hawk and the Stanley hawk, according to Audubon. The former of these hawks, silently perched on the tops of trees, seizes his opportunity and dashes irresistibly down upon them; the latter gliding rapidly through the woods pounces upon them before they are aware of their danger. Among the quadrupeds, pole-cats, weasels, racoons, opossums, and foxes, are said by the same author to be destructive foes to them.

The following is Sir John Richardson's description of a male killed on the 4th of May, on the Saskatchewan plains:—

"Back, rump, and upper tail-coverts chestnut-brown, mottled and finely undulated with blackish-brown; the broad tips and a cordiform central mark on each feather pale-gray. Back of the neck, scapulars, and wing-coverts having the same colours; but the gray tips very narrow, the blackish-brown in large blotches, and instead of central marks, stripes along the shafts of orange-brown and brownish-white. Top and sides of the head, the tertiaries, and outer edges of the secondaries, mottled with the same. Eye stripe from the nostrils whitish. Shoulder-tufts velvet-black, glossed with dark-green. Quills liver-brown, the outer webs barred near the base and mottled towards the tips with cream-yellow. Tail gray, finely undulated, and also crossed by about nine narrow bars and a broad subterminal one of blackish-brown. Throat and breast yellowish-brown, belly and vent brownish-white; are remotely barred, but most broadly on the sides of the belly, with blackish-brown, which also forms a band across the upper part of the breast between the ruffs. Inner wing-coverts and axillaries clove-brown, barred and tipped with white. Bills and nails dark horn-colour. A male killed at the same time with the preceding, and of equal dimensions, shows more of the chestnut or orange-brown in its plumage, and the ground colour of its tail is yellowish-brown, the extreme tips and a bar next the broad subterminal dark one being gray. Females have less of the blackish-brown colour; the shoulder-tufts are orange-brown instead of black; and the subterminal bar on the tail is chestnut-coloured. In young birds orange-brown is the prevailing tint of colour. They have a short crest on the top of the head: a fringed comb over the eye in the male. Shoulder tufts consisting of about fifteen fan-shaped feathers. Fourth quill the longest, slightly exceeding the third and fifth. Tail fan-shaped, of eighteen feathers, the central pair more

Ruffed Grouse (*Bonasia Umbellus*), male.

than half an inch longer than the outer ones; the individual feathers nearly square at the end. Tarsus feathered more than halfway down anteriorly, and about half an inch lower posteriorly. All the toes strongly pectinated."

The dimensions on an average may be taken as 18 inches in length, and 23 or 24 inches in extent.

Sir John Richardson states, that after a careful comparison of the specimens of Mr. Douglas's *Tetrao Sabini*, deposited in the Edinburgh Museum, they appeared to differ in no respect from the young of *Tetrao Umbellus* (*Bonasia*), and that the characters by which Mr. Douglas distinguishes his bird are equally applicable to the latter.

Douglas also found in the valleys of the Rocky Mountains, 54° N. lat., and a few miles northward, near the sources of Peace River, a bird which he regarded as a variety of *B. Umbellus*.

BONASSUS. [BISON.]

BONE, the organ which in higher animals forms the basis of the fabric of the body. Many of the creatures placed at the bottom of the animal scale, composed of soft gelatinous matter, and buoyant in water, need no solid support; but all animals that possess solid organs, and whose body rests upon particular points, must have some substance of a dense and inflexible nature to afford to their various tissues and structures the requisite resistance and support. The substances that serve this purpose are various, but the most common are the salts of lime, sometimes the carbonate, sometimes the phosphate, and at other times both combined in different proportions. Carbonate of lime constitutes the solid basis of many of the compound zoophytes and the corals. It also constitutes the principal part of the fabric of the shells of *Mollusca*. It is found also in the external skeleton of the *Crustacea*, as the crabs and lobsters, but in this instance the phosphate of lime is also present, and predominates. It is in the skeletons of the Vertebrate animals that we find the phosphate of lime greatly preponderating. This is characteristic of bone.

When an animal possesses bone as the solid support of its fabric it indicates a high degree in the scale of organisation. Bone is an elaborate structure found in no class below the *Vertebrata*. Even the lowest order of this, which is the highest class of animals, is wholly destitute of it; for it is not found in large tribes of fishes, the shark, the sturgeon, the ray, &c. In these the less highly-organised substance called cartilage is substituted, and accordingly these fishes are called cartilaginous in contradistinction to the osseous; and in all classes below the cartilaginous fishes the dense and inflexible substance which sustains the soft parts of the body, and which affords points of resistance for the action of those parts, consists either of shells or of some modification, and not of true organised bone.

In general the structure which performs the office of bone in the lower animals is placed on the exterior of the body, and often indeed forms its external envelope; true bone, on the contrary, is always placed in the interior. Even when it approaches the surface bone is always covered by some soft part, as muscle, membrane, skin, &c. Crust, shell, horn—the substances which form the skeleton of the inferior animals—are thus external, the soft parts being internal; but in the higher animals the skeleton is always internal, and the soft parts, which are sustained by it and which re-act upon it, are external.

The office of bone in the animal economy is chiefly mechanical, and the mechanical purposes to which it is subservient require that it should be of different sizes and forms. In the human skeleton there are commonly enumerated 260 different bones, which present every variety of size and figure. But all these varieties may be reduced to three classes: the long and round, as the bones of the upper and lower extremities; the broad and flat, as the bones of the skull; or the short and square, as the separate bones that compose the vertebral column. The long bones are adapted for motion, the flat for protection, and the square for motion combined with strength. Accordingly the long bones, which are adapted to communicate a free range of motion, are moulded into lengthened cylinders, and form so many levers, constituting organs of locomotion exquisitely constructed and combined for the accomplishment of their office, as is seen in the fin of the fish, in the wing of the bird, and in the limb of the quadruped. In the employment of the flat bones for the covering of some of the more tender and delicate organs, as the brain and spinal cord, the form of these bones is such as to add to their strength, as is manifest in the vaulted roof of the skull; while in the construction of the vertebral column, composed of the short and square bones, which are so adjusted as to afford a limited range of motion with a great degree of strength, many and opposite purposes are effected.

The structure, disposition, and connection of the individual bones accomplish in the most perfect manner the following mechanical uses:—1. By their hardness and firmness they afford a support to the soft parts, forming pillars to which the more delicate and flexible organs are attached, and kept in their relative positions. 2. By the same properties of hardness and firmness they defend the soft and tender organs, by forming solid and strong cases in which such organs are lodged and protected; as the case formed by the bones of the cranium for the lodgment and protection of the brain; by the bones of the vertebral column for the lodgment and protection of the spinal cord; and by the bones of the thorax for the lodgment and protection of the lungs, the heart, and the great vessels connected with it. 3. By affording fixed points for the action of the muscles, and by assisting in the formation of joints, they aid and are indeed indispensable adjuncts to the muscles in accomplishing the function of locomotion.

Bone is a complex organ, and the arrangement and combination of its constituent parts are highly curious. It is composed essentially of two distinct substances, an animal and an earthy matter. The animal matter is composed of gelatine; the earthy matter consists principally of phosphoric acid combined with lime, forming phosphate of lime.

This structure of bone is rendered manifest by subjecting it to certain chemical processes. If a bone be placed in a charcoal fire, and the heat be gradually raised to whiteness, it appears on cooling as white as chalk; it is extremely brittle; it has lost very much of its weight, yet its bulk and shape are little changed. In this case the membranous matter is wholly consumed by the fire, while the earth is left unaltered. Over the surface of a bone so treated are visible a number of minute crevices, the spaces which were filled in the natural state of the bone with the animal matter; and on breaking the bone across, the size and shape of the cavities which contained the marrow become manifest. If on the other hand the same bone be placed in an acid sufficiently diluted to prevent its injuring the animal membrane, and yet strong enough to dissolve the phosphate of lime—if for this purpose it be macerated in diluted nitric or hydrochloric acid—every particle of the phosphate of lime may be removed, and the animal matter alone will remain perfectly uninjured and unaltered. Accordingly the remaining substance retains the exact figure and dimensions of the original bone, but it has lost all its other mechanical properties. It is so soft and flexible that if either of the long bones of the human arm—that, for example, called the radius—be treated in this manner, it can with the utmost ease be tied in a knot. By the first process the earth is obtained, deprived of its animal constituent; by the second, the membranous matter free from the earth. In the bone both are combined; in every constituent atom of it there is an earthy in intimate combination with an animal matter. The first gives it hardness, the second tenacity; and thus by the intimate combination of these elements two qualities which in unorganised matter are scarcely compatible are combined. By increasing the proportion of phosphate of lime any degree of hardness can be obtained: the bony portions of the ear, the bony portions of the teeth, for example, are as hard as marble, or even flint; but substances so hard would not do for the ordinary purposes of bone, because they would be brittle in proportion to their hardness, and would be productive of fatal mischief whenever they were subject to any sudden and violent concussion.

In certain diseased states of the human system the earthy matter preponderates in the whole osseous system, and in this condition persons are liable to fracture their bones by the slightest accident. On the other hand, the earthy matter is sometimes deficient; then the bones give way and become bent, and ultimately the body becomes an immoveable mass.

Bones not only differ so much from one another in their comparative hardness according to the office which each has to serve that no two bones possess the same degree of rigidity, but no bone is equally hard in its entire substance. When a section of a bone is made in such a manner as to show its structure throughout, it is seen to consist of two varieties, a hard or compact and an alveolar or spongy substance. In general the compact forms the external and the spongy the internal portion of the bone; the compactest part of the bone forms a completely solid body, exhibiting scarcely any visible arrangement, without apparent fibres and laminæ; but towards the inner part of the bone the substance becomes less and less dense, until at length it presents the appearance of minute and delicate fibres, which intersect each other in every direction, forming the cells termed cancelli (lattice-work). The transition from the compact to the spongy or cancellated part is not marked by any distinct boundary; the one passes into the other by insensible degrees, showing that there is no essential difference between them; and indeed the evidence is complete that, although in the densest part of the bone there is scarcely any trace of specific organisation, it is made up of fibres and plates perfectly similar to those of the spongy or cancellated part, differing from it principally in its greater degree of condensation. Often in the centre of the bone there is scarcely any even of the spongy matter, but a hollow space is left, which is filled up with a series of membranous cells in which the substance called marrow is lodged.

In the arrangement of the fibres in different bones, so as to adapt them to the specific offices they have to serve, there is exquisite mechanism. Where the principal object is either extensive protection, or the provision of broad surfaces for the attachment of muscles, the osseous fibres are so disposed as to form flattened plates, as in the bones of the skull. When on the other hand a system of levers is wanted, as in the limbs which have to sustain the weight of the trunk, and to confer extensive powers of locomotion, the bones are modelled into lengthened cylinders, generally somewhat expanded at the extremities for greater convenience of mutual connection. The shank or body of this hollow cylinder consists principally of compact with but little spongy matter, while the extremity or head of it is principally composed of spongy matter, with only a thin crust of compact substance. The principal mechanical property required in every cylindrical lever is rigidity, and more especially the power of resisting forces applied transversely, that is, tending to break the cylinder across; it has been often stated that a given quantity of materials could not possibly have been disposed in a manner better calculated for such resistance than those in the form of a tube or hollow cylinder. The hollow stems of vegetables derive their chief strength from possessing this form. Bones also are rendered both lighter and stronger by being made hollow than if the cylinder had been solid; and as it is in the middle of the shaft that the strain is greatest, so it is here that the cavity is largest and the resistance most effectual.

Bone has been recently submitted to rigid chemical analysis, and the result is that in healthy bone about two-thirds, or 66·7 per cent., consist of saline or earthy matters, and 33·3 per cent., or one-third, of animal matter. The bones of children contain more animal matter, and of aged persons more earth. Different bones also in the same skeleton contain different proportions of these constituents. Thus, according to Dr. G. O. Rees, the bones of the head and the limbs contain more earth than those of the trunk. The following are two ultimate analyses of bone from Dr. Sharpey's Introduction to 'Quain's Anatomy:' the one is by Berzelius, the other by Mr. Middleton of University College:—

	Berzelius.	Middleton.
Animal Matter	33·30	33·43
Phosphate of Lime	51·04	51·11
Carbonate of Lime	11·30	10·31
Fluoride of Calcium	2·00	1·99
Magnesia, wholly or partially in the state of a phosphate	1·16	1·67
Soda and Chloride of Sodium . . .	1·20	1·68

The phosphate of lime in bones is peculiar, and is known amongst chemists as the 'bone-earth phosphate.' It is what is called a tribasic phosphate, consisting of 8 equivalents of lime, 3 of phosphoric acid, and 10 of water. Fluoride of calcium is found in larger quantities in fossil than in recent bones; and such is its abundance in some fossils, as those brought from the Sevalik Hills, in India, by Dr. Falconer, that we must have recourse to the supposition of a substitution of this substance for phosphate of lime, in order to account for its presence.

We have referred to the statement that the bones of the limbs contain more earth than the trunk. The following analysis by Lehmann shows that the bones of the arms and legs have a different compostion:—

	Humerus.	Femur.
Phosphate of Lime and Fluoride of Calcium	56·61	58·93
Carbonate of Lime	9·20	9·28
Phosphate of Magnesia	1·08	1·09
Chloride of Sodium	0·37	0·40
Soda	1·35	1·04
Organic Matter	31·52	28·61

When examined under the microscope, sections of the different bones present very different appearances, not at first easily reconciled with a common mode of origin or growth. The result of a close investigation, however, shows that the osseous tissue like all other parts of the body originates in cells. This fact is not easily traced, and we shall first speak here of the appearances presented on a minute examination of the texture of the bone.

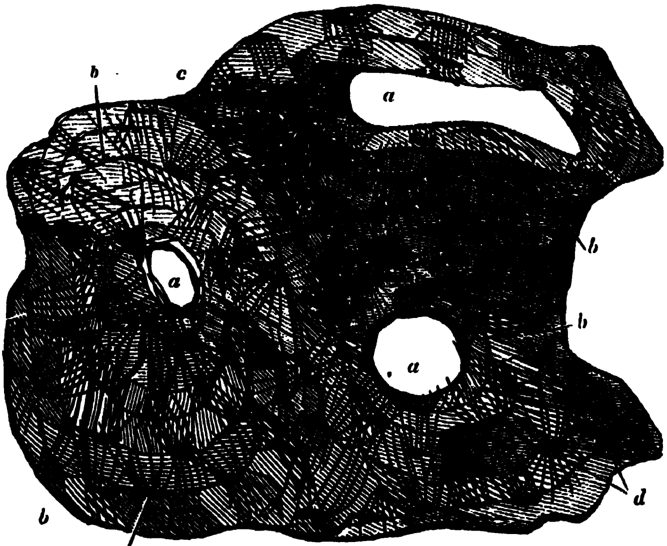


Fig. 1.—Transverse Section of the dense portion of the [illegible] a, Haversian Canals; b, concentric laminæ; c, laminæ of co[illegible]; d, corpuscles with their system of tubes. The parts marked a, b, an[illegible] constitute an Haversian system.

The canals which are everywhere found traversing variously the substance of bone, and giving passage to the blood-vessels for the nourishment of the tissue, are called Haversian Canals, a name given them in consequence of Clopton Havers having been the first who gave a full account of them. The parietes of these canals have a laminated arrangement. The laminæ themselves are numerous and placed concentrically; the internal lamina, that which is in immediate contact with the vessel or vessels, being the most distinctly marked, and each succeeding one having a less distinct outline.

Besides the concentric laminæ, there are others which surround the exterior of the bone, and may be known as the superficial laminæ. In connection with both the concentric and superficial laminæ are a third set, which cannot belong to either of the other orders, but which are placed between them, and form the bond of union between each system.

Much has been lately written on the bone-corpuscles. These are small cells of oval form placed between the laminæ, and having numerous distinct tubes running from them in almost every direction. They have been sometimes compared to a spider with many legs. The corpuscles, or as they are occasionally called the calcigerous cells, have a definite relation to the Haversian Canals and to each other.

The Haversian Canals, the Osseous Laminæ, and the Bone-Corpuscles are therefore the leading points to be mentioned in treating of the structure of the bone. Upon a closer view, however, it will be seen that it is only the laminæ which are bone; the canals and corpuscles are spaces existing in bone, and are not really necessary to the existence of osseous tissue, though they are requisite where the amount of substance is appreciable to the unaided senses.

Of the Substance of Bone, or Hyalitic Substance.—The substance of bone has been considered, with but one or two exceptions, as homogeneous, and without appreciable structure. If it be examined however under advantageous circumstances, with high magnifying powers, there will be no difficulty in detecting a very definite though delicate structure. A very small portion of a thin plate of bone should be taken for the purpose of examination: such may be found in the ethmoid bone of small animals, as of the rat. If the piece is properly chosen it will be found to contain no Haversian Canals nor corpuscles, but will be extremely thin and transparent. A piece of this kind will present a delicate granular aspect with the surface nodulated. This granular appearance proceeds from the substance of the bone being composed of minute irregularly spherical granules. This structure may be traced without much difficulty in any specimen of bone, although it varies much in distinctness in different specimens. The object should be placed between two slips of glass with a little plain water for examination. A delicate spiculum from the point where ossification is going on illustrates the granular tissue exceedingly well. The granules may be obtained separated from each other, so that each individual may be examined independently of the others. When seen in this manner they exhibit a tolerably regular character, being mostly spherical, though a few have an oval form. In a few specimens the oval form predominates.

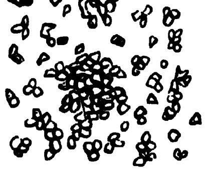

Fig. 2.—Ultimate osseous granules, obtained by depriving bone of its animal matter.

Of the Laminæ.—The form assumed by the osseous tissue is that of laminæ, and these laminæ have a definite arrangement, so much so that three distinct systems are recognised, namely, laminæ of the Haversian Canals; secondly, the laminæ which connect the Haversian systems; and, thirdly, the laminæ which form the surface of the bone, and inclose the two previous orders. The laminæ of the Haversian Canals have a concentric arrangement, and when divided transversely present a series of more or less distinct and perfect rings. They vary very much in number, but the most common amount is ten or twelve. Of these, the internal lamina, that which forms the parieties of the Haversian Canal, is most distinctly marked, while each succeeding one as we proceed outwards becomes less distinct. Connecting these Haversian systems is a second series of laminæ, without which the former would exist but as a bundle of loose tubes (*fig.* 1, *c*). In this substance we find the laminated arrangement less distinct, far less regular, and the laminæ individually subject to great irregularity of thickness. They are generally more transparent than either the Haversian or external system. The last division consists of those laminæ which surround the exterior of the bone. These have greater individual extent, but are the least numerous. They are continuous with the laminæ of the Haversian system whenever the latter arrive at the surface of the bone; the external laminæ in this case being continuous with the inner laminæ of the Haversian system.

The effect of madder upon the osseous system, when given to an animal with its food, may here be noticed, since the colour is imparted to the laminæ. By introducing madder into the stomach, a deep red tinge is very soon observed: in a pigeon the bones were rendered brilliantly red in 24 hours. A similar effect was produced on a young pig in three weeks. On making sections of bone so affected, the colour is found to be present in the external laminæ of the bone, and in the inner laminæ of the Haversian system, thereby proving that the action of colouring takes place upon those surfaces which lie in contact with vessels.

Of the Haversian Canals.—These canals must be considered in relation to their number, their size, and the parts which they contain. The number of canals in a given space varies perhaps a little, but this variation will be regulated in some degree by the situation of the bone, but more especially by its age. Thus the transverse section of the femur of a human fœtus of seven months will present many more canals than a section of equal measurement from the femur of an adult. The size of the Haversian Canals takes a considerable range, varying from the 300th to the 500th of an inch. The Haversian Canals undoubtedly give passage to blood-vessels, this being their principal if not only purpose.

The Corpuscles or *Cells of Bone* cannot be described as having any definite unvarying shape or size. The general form is a compressed oval, though not unfrequently they are circular. Again, they are sometimes almost triangular in their outline, while in other instances they approach a linear shape. These are the most common varieties of outline to which the bone-cells are subject, as they occur in the bones of man and the higher animals. In the four great classes of animals, namely, mammalia, birds, reptiles, and fishes, it has been shown by Professor Quekett that there are certain characters connected with these cells by which a bone of one class of animals may be distinguished from that of another, and that the size of these cells bears a direct relative proportion to that of the blood-corpuscles. He has shown that they are smallest in birds, a little larger in mammals, and largest of all in the reptiles; while in fishes they are altogether unlike those in the preceeding classes. The importance of this observation in relation to fossil osteology is obvious. Connected with the cells are numerous delicate branching tubes, called canaliculi, which are slightly dilated as they enter the cells. The number arising from each cell does not allow of any very definite enumeration, since no two cells will be found possessed of a like number of branching tubes. The general arrangement of the tubes is radiate as regards the cells which form their common centre. The connections are so numerous between the tubes and between the cells through the tubes, that a fluid introduced into one cell in a bone, may enter every other cell in that bone. The cells are situated between the laminæ, or on their surface; but where concentric laminæ occur, as in the Haversian system, the cells are placed in circular lines between the laminæ, each line of cells having the Haversian Canal as an exit common to it and the connecting laminæ. When the canals for vessels are in great abundance, the bone-cells are more rarely met with; indeed in some cases they are almost entirely absent. When the cells are seen by transmitted light, particularly in a transverse section of bone, they are frequently opaque. There is no doubt that the bone-cells perform the function of circulation.

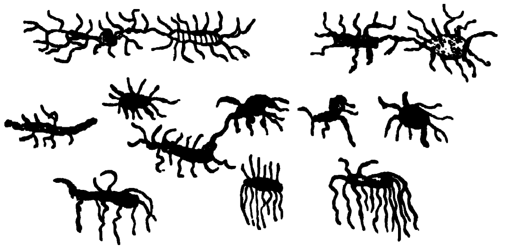

Fig. 3.—The Forms assumed by the Bone-Cells in Man.

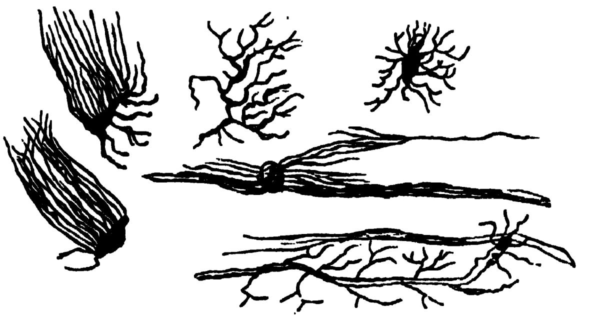

Fig. 4.—Various Forms of Bone-Cells in the Bone of the *Boa Constrictor*.

Formation of Bone.—The commencement of the growth of bone is generally preceded by the formation of a cartilaginous matter which occupies the place afterwards taken by bone. From this circumstance it has been supposed that bone is formed from the ossification of cartilage. This however is not the case, as it is found that although ossification takes place in the first instance in cartilage, the bony matter thus formed has not a permanent character. The formation of bone always takes place in the first instance in the immediate neighbourhood of blood-vessels in canals excavated in the cartilaginous substance, and the spots where these canals are formed are called centres of ossification. There is usually one of these in the centre of a long bone and one at each end, and frequently another for any considerable process or projection, such as the trochanter in the femur of the human body. Up to the time that the bone is fully formed these centres are only connected by cartilage, and this arrangement serves the obvious purpose of allowing the increase of the whole bone by means of cartilage until the time comes when no further increase of size is needed. In the early conditions of the skeleton of the vertebrate animals there is a much closer correspondence in this respect than is subsequently seen; for according to the habits of the animal the whole of the cartilage is converted into bone, or by its absorption and disappearance separate bones are formed. It is upon this fact that the science of transcendental anatomy rests, in which the whole of the modifications of the vertebrate skeleton are referred to departures from a type which is found generally to exist in the embryo condition of the whole class. Thus it is found, from an extensive comparison, that the regular number of distinct bones in the wrist (carpus) and instep (tarsus) is ten, but in the human wrist the number is reduced to eight and in the instep to seven, whilst the reduction is still greater in the hoofed mammalia. [Skeleton.]

The structure of the temporary cartilage of bone is precisely the same as permanent cartilage. The first calcareous deposit is made in the space between the proper cells of the cartilage. These cells subsequently disappear leaving large open areolæ having no very definite form. In these areolæ there is subsequently deposited a fluid blastema containing cells, and through the agency of this blastema the Haversian canals and cancelli appear to be formed, whilst the interspersed cells are changed into the bone-cells and their projecting canaliculi. Although in most instances the formation of bone is preceded by that of cartilage, yet this is not universally the case, as we see bone formed in the substance of the tissues, as for instance the fibrous membrane. This is seen in the development of the bones of the roof of the skull, and also in the growth of bones subsequently to their first development by the progressive calcification of the inner layers of the periosteum, or fibrous covering of the bones.

It has been stated that the central cavities of some of the larger bones are filled with the substance called marrow, an oily matter contained in a series of membranous cells, which, like those in which the fat is deposited do not communicate with each other. Even the pores and cancelli of bone also contain a kind of oily matter, which is supposed to differ from marrow only in possessing a greater degree of fluidity. This oily matter is deposited in longitudinal canals, which pass through the solid substance of the bone, together with its nutrient vessels. The use of the marrow, and of the modification of it which constitutes the oily matter, is not well understood. Without doubt it serves the same general use in the economy as the other oily secretions. [Adipose Tissue.]

All bones are covered by a membrane, named, on account of its affording them an external envelope, Periosteum. The outer surface of this enveloping membrane is connected to the surrounding parts by cellular tissue, but its inner surface is firmly adherent to the substance of the bone. This adhesion is effected by innumerable fibres or threads, which on examination are found to consist of blood-vessels. The periosteum is in fact the membrane on which the nutrient arteries of the bone rest, divide, and ramify in order to enter the osseous substance. These threads are much more numerous in the child than in the adult; and accordingly the adhesion of the periosteum to the bone is much firmer in the former than in the latter, as the quantity of blood distributed to the bone is greater. Moreover, in general the inner surface of bones is also lined by a fine and delicate membrane, commonly termed the internal periosteum, the continuation of which forms the membranous bags in which the marrow is contained.

BONE-BEDS. Accumulations of the bones of extinct animals, more especially of fish and Saurian reptiles, are not uncommon in various strata, and have had this name given them by geologists. They generally occur at the termination of one formation and the commencement of another. These Bone-Beds are local, and are not in any case very extensive. The thickest and most widely-distributed is that of the Lias, which seems to mark the commencement of the New Red-Sandstone epoch. The most remarkable Bone-Beds are the following:—

Bone-Bed at the base of the Lower Greensand at its junction with the Wealden; at the base of the Inferior Oolite, at its junction with the Lias; at the base of the Lias, at its junction with the New Red-Marl; at the base of the Mountain Limestone, at its junction with the Old Red-Sandstone; at the base of the Old Red-Sandstone, at its junction with the Ludlow Rock of the Silurian System.

(Brodie, *On the Basement-Beds of the Inferior Oolite*; *Proc. Geol. Soc.*

BONE-DOG, a name given in Sussex to the picked Dog-Fish (*Acanthias vulgaris*, Risso). [Squalidæ.]

BONE'LLIA, a genus of *Echinodermata*, formed by Rolando, and placed by Cuvier in the tenth order of his first class of Zoophytes, the

Echinoderms (*Echinodermatous Radiaria*) of Lamarck. This tenth order consists of the Footless Echinoderms, and *Bonellia* forms its sixth genus. Cuvier says that *Bonellia* has an oval body and a proboscis formed of a folded fleshy plate (lame) susceptible of great elongation and forked at its extremity. The vent is at the opposite end of the body; the intestine is very long, being folded several times, and near the vent are two ramified organs for the purpose of respiration. The eggs are contained in an oblong sac which has its opening near the base of the proboscis.

The animal is described as living deep in the sand, and projecting its proboscis till it arrives at the water when it is high, or till it reaches the air when the water is low.

The cut represents *Bonellia viridis*, which is found in the Mediterranean.

Bonellia viridis.

BONGAR, a name given to the Rock-Snake of the East Indies. [Boidæ.]

BONGARDIA, a genus of plants belonging to the natural order *Berberidaceæ*. [Berberidaceæ.]

BONITO, the name of Fishes belonging to the family *Scomberidæ*. They resemble the Tunny. The Bonito is the *Thynnus pelamys*, Cuv.; the Belted Bonito, *Pelamys Sarda*, Cuv.; the Plain Bonito, *Auxis vulgaris*, Cuv. [Thynnus.]

BONPLANDIA, a genus of plants belonging to the natural order *Rutaceæ*. The only species described, *B. trifoliata*, yields the Angostura Bark. The genus is now referred to *Galipæa*. [Galipæa.]

BONSDORFITE, a mineral belonging to the group of double hydrous Silicates of Alumina, to which the term *Zeolites* has been applied. The following is the analysis of this mineral by Bonsdorf, after whom it is named:—

Silica	45·05
Alumina	30·05
Magnesia, with a trace of Manganese . .	9·00
Protoxide of Iron	5·30
Water	10·60
	100·00

It occurs crystallised in regular six-sided prisms, the lateral edges of the prism being usually replaced by so many planes that the prism appears almost cylindrical. The cross fracture is conchoidal. The texture foliated, the foliations being perpendicular to the axis of the prism. The colour is a greenish-brown or dark olive-green. Lustre of the faces like that of talc, of the cross fracture waxy. Opaque in thick plates, translucent in thin plates. This mineral is found in a red granite, at Birkopsokern near Abo in Finland.

BONUS HENRICUS, a kind of weed, formerly supposed to possess medicinal properties. [Chenopodium.]

BOOBY, the English name for a genus of *Pelecanidæ* (*Dysporus* of Illiger, *Morus* of Vieillot, Les Fous of the French), separated with good reason from the true Pelicans by Brisson under the name of *Sula*.

The term Booby is more particularly applied by navigators to that species (*Sula fusca* of Brisson) which inhabits the desolate islands and coasts where the climate is warm or even temperate throughout the greater part of the globe. The apparent stupidity of the Boobies is proverbial; calmly waiting to be knocked on the head as they sit on shore, or perching on the yard of a ship till the sailor climbs to their resting-place and takes them off with his hand, they fall an easy prey to the most artless bird-catcher. Even Byron's shipwrecked wretches, though

> ——— "Stagnant on the sea
> They lay like carcases,"

"caught two boobies and a noddy;" and the incident actually did occur in Bligh's celebrated boat-voyage, consequent on the mutiny on board the Bounty, when he and his boat's crew were in a most deplorable state.

"Monday, the 25th," says Bligh, "at noon, some noddies came so near to us that one of them was caught by hand. . . . In the evening, several boobies flying very near to us, we had the good fortune to catch one of them. . . . I directed the bird to be killed for supper, and the blood to be given to three of the people who were the most distressed for want of food. The body, with the entrails, beak, and feet, I divided into eighteen shares. . . . Tuesday, the 26th. In the morning we caught another booby, so that Providence appeared to be relieving our wants in an extraordinary manner. The people were overjoyed at the addition to their dinner, which was distributed in the same manner as on the preceding evening, giving the blood to those who were the most in want of food."

Dampier says that in the Alcrane Islands (Alacranes), on the coast of Yucatan, the crowds of these birds were so great that he could not pass their haunts without being incommoded by their pecking. He observed that they were ranged in pairs, and conjectured that they were male and female. He succeeded in making some fly away by the blows he bestowed on them, but the greater part remained in spite of his efforts to compel them to take flight. De Gennes, in his voyage to the Straits of Magalhaens, says that in the Island of Ascension there were such quantities of Boobies that the sailors killed five or six at a time with one blow of a stick. The Vicomte de Querhoent says that the French soldiers killed an immense quantity at this same island, and that their loud cries when disturbed at night were quite overpowering.

This apparent exception to the general rule of self-preserving instinct is so remarkable, that we are led to look for some cause, and perhaps this is to be found in the structure of the animal; for according to many writers whose veracity cannot be questioned, the Boobies stay to be taken and killed after they have become familiar with the effect produced by the blows or shot of their persecutors. In the case of most other animals, which, from not knowing his power, have suffered man to approach them to their destruction, alarm has been soon taken, the idea of danger has been speedily associated with his appearance, and safety has been sought in flight; but the wings of the Booby are so long and its legs so short, that when once at rest on level ground the bird has great difficulty in bringing the former into action, and when so surprised it has no resource but to put on a show of resistance with its beak, which is to be sure generally despised by the aggressor.

In the cases recorded by Bligh the birds were probably fatigued by wandering too far from the rocky shores, which are their ordinary haunts. There they are generally to be seen constantly on the wing over the waves which beat at the foot of the crags, intent on fishing. Though so well furnished with oars, they are said to swim but seldom, and never to dive. Their mode of taking their prey is by dashing down from on high with unerring aim upon those fishes which frequent the surface, and instantly rising again into the air. They walk with difficulty, and when at rest on land their attitude is nearly vertical, and they lean on the stiff feathers of the tail, like the cormorants, as a third point of support. The ledges of rocks or cliffs covered with herbage are the places generally selected for the nest, and there in great companies they lay their eggs, each hen bird depositing from two to three. The young birds for some days after their exclusion are covered with a down, so long and thick that they resemble powder-puffs made of swan's down.

The Boobies seldom wander more than twenty leagues from land, to which they usually return every evening, and their appearance is considered by mariners as a sure token of their vicinity to some island or coast.

The colour of the *Sula fusca*, or Brown Booby, is blackish-brown, or ashy-brown above and whitish beneath; the primaries are black, and the naked skin about the face is reddish; the orbits and base of the bill are yellow, and the point of the bill is brown; the legs are of a straw colour.

In length the Brown Booby is about 2 feet 5 inches, the bill measuring 4½ inches or thereabout, and the tail 10 inches: the young birds are spotted with white and brown.

It is almost impossible to open the pages of the old voyagers who have fallen in with these Boobies without finding some entertaining accounts of the constant persecution to which the latter are subjected by the Frigates or Man-of-War Birds. Lesson indeed doubts this. He says, "The boobies have been so named because it has been supposed that the frigates compelled them to disgorge the fish which they had taken; but this appears to us to be erroneous. The booby is warlike, he lives fearlessly near the frigate, and swallows the fish which he has captured in peace." Buffon, Cuvier, and Temminck, on the contrary, evidently give credence to the narratives of the Frigate-persecution, and indeed it is difficult to believe that so many eyewitnesses should be mistaken.

Brown Booby (*Sula fusca*).

Feuillée says, "I have had the pleasure of seeing the frigates give chase to the boobies. When they return in bands towards evening from their fishing, the frigates are in waiting, and dashing upon them compel them all to cry for succour, as it were, and, in crying, to disgorge some of the fish which they are carrying to their young ones. Thus do the frigates profit by the fishing of the boobies, which they then leave to pursue their route." Leguat in his voyage thus writes:—"The boobies come to repose at night upon the Island Rodriguez, and the frigates, which are large birds, so called from their lightness and speed in sailing through the air, wait for the boobies every evening on the tops of the trees. They rise on the approach of the latter very high in the air and dash down upon them like a falcon on his prey, not to kill them but to make them disgorge. The booby, struck in this manner by the frigate, gives up his fish, which the frigate catches in the air. The booby often shrieks and shows his unwillingness to abandon his prey, but the frigate mocks at his cries, and rising dashes down upon him anew till he has compelled the booby to obey." William Dampier observes that he remarked that the man-of-war birds and the boobies always left sentinels near their young ones, especially while the old birds were gone to sea on their fishing expeditions; and that there were a great number of sick or crippled man-of-war birds which appeared to be no longer in a state to go out for provision. They dwelt not with the rest of their species, and whether they were excluded from their society or had separated themselves voluntarily, they were dispersed in various places waiting apparently for an opportunity of pillage. He adds that one day he saw more than twenty on one of the islands (the Alcranes), which from time to time made sorties to procure booty. The man-of-war bird that surprised a young booby without its guard gave it a great peck upon the back to make it disgorge (which it instantly did) a fish or two as big as one's wrist, which the old man-of-war bird quickly swallowed. He further speaks of the persecution of the parent boobies by the able-bodied frigates, and says that he himself saw a frigate fly right against a booby, and with one blow of its bill make the booby give up a fish just swallowed, upon which the frigate darted with such celerity that he seized it before it reached the water. Catesby and others mention similar encounters. Nuttall says, "The boobies have a domestic enemy more steady, though less sanguine in his persecutions, than man; this is the frigate pelican or man-of-war bird, who with a keen eye descrying his humble vassal at a distance, pursues him without intermission, and obliges him by blows with its wings and bill to surrender his finny prey, which the pirate instantly seizes and swallows.

The booby utters a loud cry, something in sound betwixt that of the raven and the goose; and this quailing is heard more particularly when they are pursued by the frigate, or, when assembled together, they happen to be seized by any sudden panic."

Their nests, according to Dampier, are built in trees in the Isle of Aves, though they have been observed in other places to nestle on the ground. They always associate in numbers in the same spot, and lay one or two eggs. The young are covered with a very soft and white down. Nuttall says that they abound on rocky islets off the coast of Cayenne and along the shores of New Spain and Caracas, as well as in Brazil and on the Bahamas, where they are said to breed almost every month in the year. In summer, he adds, they are not uncommon on the coasts of the Southern States of North America. The flesh he describes as black and unsavoury.

Other species of *Sula* are also called Boobies. [Sula.]

BO'OPS, a genus of Fishes of the order *Acanthopterygii*, and, according to Cuvier's arrangement, belonging to the fourth family of that tribe called *Sparoïdes* or *Sparidæ*.

This genus is chiefly characterised by the species possessing trenchant teeth; the mouth is small and not protractile. The species are generally of brilliant colouring. Most of them occur in the Mediterranean.

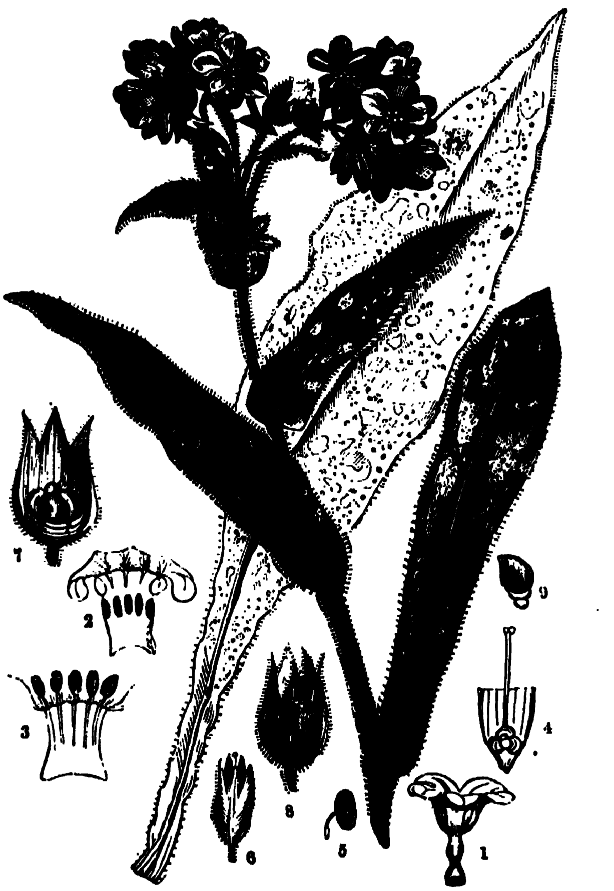
Boops salpa (*Sparus salpa* of Linnæus) is of an oblong-ovate form. The ground colour of its body is bluish, on which are several longitudinal yellow stripes.

BOOTTIA, a genus of plants belonging to the natural order *Hydrocharidaceæ*, the species of which are eaten as pot-herbs.

BORACITE. [Boron.]

BORAGE. [Borago.]

BORAGINA'CEÆ, *Borage-Worts*, the Borage Tribe, a natural order of regular-flowered Monopetalous Dicotyledons, which are readily distinguished from all others by having their ovary deeply divided into four lobes, from the middle of which arises a single style. They are moreover characterised by their flowers being arranged in a gyrate manner before they expand. The Common Borage is often taken as the type of this order, and in fact represents not only its peculiarities of structure, but sensible properties; for all the known species agree in having an insipid juice, and their surface covered over with stiff white hairs, which communicate a peculiar asperity to the skin, whence these plants were formerly called *Asperifoliæ*, or 'rough-leaved.' In the structure of their ovary these plants are closely allied with *Lamiaceæ*. Their regular flowers and the absence of volatile oil in



Lung-Wort (*Pulmonaria angustifolia*).

1, A corolla; 2, the same cut open; 3, the tube of the same; 4, the base of the same with the ovary and its four lobes; 5, an anther; 6, calyx; 7, a section of the calyx, showing the four-lobed fruit; 8, a ripe calyx; 9, an achenium.

their leaves, and five stamens, at once distinguish them. They also resemble *Nolanaceæ*, but from these they are distinguished by their gyrate inflorescence. The species are principally natives of the temperate countries of the northern hemisphere. The properties of this order are not active. Nevertheless several have been used in medicine; one species yields alkanet, and many of them are cultivated. It contains 53 genera and about 600 species. [ANCHUSA; ECHIUM; PULMONARIA; STEENHAMMARIA; LITHOSPERMUM; MYOSOTIS; SYMPHYTUM; BORAGO; CYNOGLOSSUM.]

BORA'GO, a genus of plants, the type of the natural order *Boraginaceæ*, and placed in the tribe *Anchuseæ*. This tribe is distinguished by possessing four nuts affixed to an hypogynous disk, with an excavated space surrounded by a tumid ring at their base. The genus *Borago* has a calyx with five deep segments; a rotate corolla with the tube very short, the throat with short erect emarginate scales; exserted stamens, the filaments bifid, the inner fork bearing the anther; the anthers linear, lanceolate, connivent in the form of a cone. All the species are rough plants, with fusiform roots, oblong or lanceolate leaves, and blue panicled drooping flowers.

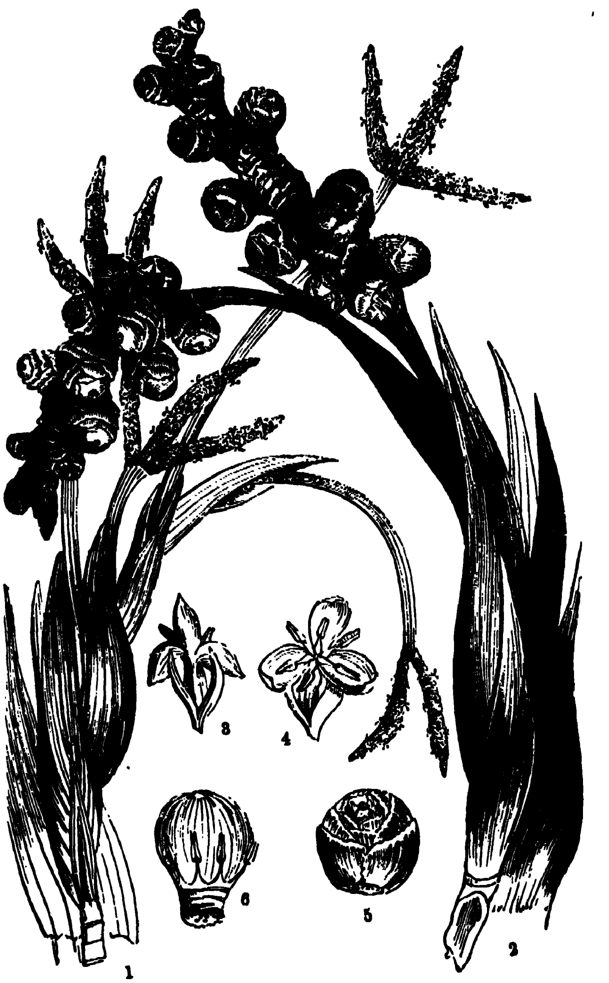
B. officinalis, Common Borage, has the lower leaves obovate, obtuse, attenuated below; the segments of the corolla ovate, acute, flat, spreading. The flowers are blue, and the whole plant is hispid, with tubercled hairs. This plant appears to be originally a native of Aleppo, but is now naturalised in most countries of Europe. In Great Britain it is not uncommon on rubbish and in waste places. Borage had formerly a great reputation as a cordial. Its virtues in this respect must have been overrated, as in common with the whole family to which it belongs it possesses no very active properties. The tissues contain gum, and on this account it may be used as a demulcent. It also possesses nitrate of potash, as well as other plants of the order, which renders it slightly febrifuge. Withering says the young tender leaves may be used as salads or as a pot-herb. Three other species are described: *B. crassifolia*, a native of Persia; *B. longifolia*, from Numidia; and *B. laxiflora*, a native of Corsica. They are all plants of the easiest culture. They may be always propagated by seed, which should be sown in the open ground. They form pretty border-flowers.

(Babington, *Manual of British Botany;* G. Don, *Gardener's Dictionary.*)

BORA'SSUS, a genus of Palms, called Tala in Sanscrit and Palmyra by the English, in imitation of the Portuguese, who name it Palmeira Brava. It is defined by Roxburgh as having diœcious hexandrous flowers; the calyx and corolla in the males consisting each of three distinct pieces, and in the females of from eight to twelve in a confused state; and the ovary of three cells, changing to a three-seeded drupe. There is but one species according to writers on Indian botany; but it is not certain that more than one distinct palm is not confounded under the common name of Palmyra.

Borassus flabelliformis is the only species. This plant grows all over India, both on the continent and in the islands, where it is esteemed of the greatest use on account of the vinous sap and the sugar which are extracted from it. Its trunk is from 25 to 40 feet high when full grown, and is perceptibly thicker at the base than at the summit. The leaves are fan-shaped, about 4 feet long, and placed upon stalks of about the same length, which are spiny at their edges; each leaf is divided into from 70 to 80 rays, which are ragged at the end, and the largest of which are placed in the centre. The fruit is about as big as a child's head, three-cornered, with the angles rounded off, and a little furrowed. It consists of a thick, fibrous, rather succulent, yellowish-brown rind, containing three seeds the size of a goose-egg. When young the shell of the seed is so soft that it may be readily pierced by the finger, and the pulpy matter which it then contains is cool and sweet and refreshing; but when ripe all this changes to a hard bluish albumen, which is insipid and uneatable. The outer wood of the stem when old becomes very hard and brown, and although scarcely to be cut transversely, nevertheless divides freely in a longitudinal direction: it is capable of taking a fine polish, and is frequently made use of for bows. The young wood in the centre is white, soft, and worthless. "This magnificent palm," says Sir William Jones, "is justly considered the king of its order, which the Hindoos call 'trina druma,' or grass-trees. Van Rheede mentions the bluish, gelatinous, pellucid substance of the young seeds, which in the hot season is cooling and rather agreeable to the taste; but the liquor extracted from the tree is the most seducing and pernicious of intoxicating juices. When just drawn it is as pleasant as Pouhon water fresh from the spring, and almost equal to the best mild champagne. From this liquor, according to Rheede, sugar is extracted; and it would be happy for these provinces if it were always applied to so innocent a purpose."

The mode of obtaining the sap of this palm is stated by Rumf to be by crushing the young inflorescence and amputating the upper half; the lower is then tied to a leafstalk, and has a vessel usually of bamboo attached to its end. The vessel gradually fills with sap, and is removed every morning; when replaced a fresh slice is cut from the wounded end of the inflorescence—an operation which is repeated daily until the whole of the raceme is sliced away. In procuring the sugar exactly the same process is followed, but the inside of the receiver is powdered with lime, which prevents fermentation taking place: the juice is afterwards boiled down and finally dried by exposure to smoke in little baskets.



Palmyra (*Borassus flabelliformis*).

1, A male spadix; 2, a female spadix, inflorescence with the spathes at its base; 3, the back of a male flower; 4, the front of the same; 5, a female flower; 6, the same stripped of its scales and showing barren stamens enveloping the ovary.

BORAX. [BORON.]

BO'RBORUS (*Iphærocera* of Latreille), a genus of Dipterous or Two-Winged Flies, of the family *Muscidæ*. Its chief characters exist in the posterior thighs, which are much compressed, and the two basal joints of the posterior tarsi, which are considerably larger than the following. The head is concave in front and reflexed towards the mouth: the antennæ diverge, and are sometimes almost as long as the fore part of the head. The second cell of the posterior extremity of the wing (the last of the two which occupy the middle of its length) is closed before it reaches the margin.

These little flies are found in marshy places, and on putrid substances, but more particularly dung-heaps, in which probably their larvæ reside; they are always abundant about cucumber frames, and are of a brownish colour; most of the species when expanded would scarcely measure a quarter of an inch.

BORECOLE, a variety of *Brassica oleracea*, also called Sprouts. [BRASSICACEÆ.]

BORER, a name for the worm-like fish, known also by the name of the Myxine, the Glutinous Hag, and Blind Fish. [GASTROBRANCHUS.]

BO'REUS (Latreille), a genus of Insects of the order *Neuroptera*, and family *Panorpidæ*. This genus, of which only one species is known (*B. hyemalis*), is not only remarkable for its structure, but from the curious circumstance of its having been found in the winter months only, and is said even to have been seen on the Alps running about on the snow: its most common abode however appears to be in moss.

B. hyemalis is about one quarter of an inch long and of a greenish colour, with the legs inclining to red; and, unlike the rest of its tribe, the female possesses no wings, and those of the male are only rudimentary. The antennæ are long and thread-like, the parts of the mouth are produced into a kind of proboscis; the abdomen of the female is furnished with a large ovipositor. It is rather a scarce insect in this country.

BORNIA, a genus of Fossil Plants from the Coal Formation, including *Bornia equisetiformis*, which Lindley ranks in *Asterophyllites* ('Foss. Flora,' t. 124).

BORON. Minerals containing Boron or any of its compounds as an essential component part are comparatively few in number, and only found in a few spots; it may be therefore considered as one of the least predominating of the elements. It is the basis of *Sassoline*, or native boracic acid; *Borax*, or borate of soda; *Boracite*, or borate of magnesia; *Datholite*, or borate and silicate of lime; and *Botryolite*. It also enters as boracic acid into the composition of *Axinite* and *Tourmaline*, but only in small quantity, most analyses giving between two and three per cent. of the acid in the former mineral, and between four and five per cent. in the latter.

The presence of Boron in any mineral may be readily detected with the blow-pipe, owing to the beautiful green tint communicated to the flame by the boracic acid. The facility with which the tint is obtained depends on the element with which the boracic acid is combined; in every instance however it may be detected by the following process:—Let a flux, composed of 4½ parts of bisulphate of potash and one of finely-powdered fluor-spar, be well mixed with about an equal quantity of the assay, which must then be formed into a paste by the addition of a little moisture. A small quantity of this being taken up on the extremity of a platinum wire must first be dried, and then exposed to a high temperature until it is fused, being held within but near the extremity of the blue flame. When the mass is fused it appears for a few moments enveloped in a pure green flame, which soon disappears, and cannot be again produced. The theory of the changes is this:—The fluorine of the flux being set free by the excess of sulphuric acid unites with the boron of the assay, forming the fluoboracic acid, which at the moment of its volatilisation communicates the green tint to the flame. This process is, however, only necessary for the detection of the boracic acid in axinite and tourmaline, as the flame is permanently coloured by sassoline, boracite, datholite, and botryolite; and the same effect is produced by moistening the glass of boron with sulphuric acid and again fusing it.

The native boracic acid is found as a deposit in several of the lagunes of Tuscany, and also in considerable abundance in the hot springs near Sasso in the same country, whence it has been called *Sassoline*. It occurs in the form of thin scaly particles, or crystalline grains either loose or aggregated in the form of a crust. These crystalline grains are hydrated boracic acid, the constitution of which may be expressed by the formula—

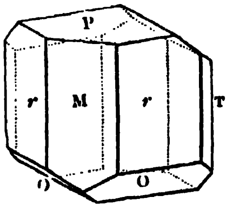
Boron 1; Oxygen 6; Water 6,

as given by Berzelius, 100 parts of sassoline being composed of boracic acid 56·37, water 43·63: their specific gravity is 1·48. The lustre is pearly, and the colour is grayish or yellowish-white: they are slightly translucent.

It loses its water of crystallisation and fuses at a very low temperature, forming a glassy globule, which is a non-conductor of electricity, and becomes resinously electric on friction. It has also been found more recently by Dr. Holland to be a deposit of the solfatara within the crater of Volcano, one of the Lipari Isles, being an exhalation of the fumaroles, around the edges of which it forms thin filaments or cakes on the surface of the sulphur.

Borax, or borate of soda, is principally employed in the arts as a flux in several metallurgical processes, and is very advantageously used in the process of soldering metals. To the chemist it is an invaluable re-agent in experimenting with the blow-pipe.

Borax is soluble in twelve times its weight of cold and twice its weight of boiling water, from which it may be readily obtained in very perfect crystals of the oblique prismatic system. The more usual form of these is represented in the accompanying figure, where the faces r are the vertical prism, the angles of which are, according to the measurements of Phillips, 86° 30′ and 93° 30′, the acuter edge of which is truncated by M, the obtuser by T, while P is the inclined terminal plane, and makes with M an angle of 106° 30′; O are the faces of a hemi-octohedron.



The following are the measurements given by Phillips:—

r on r	86° 30′
P on r	101° 30′
M on r	133° 20′
P on M	106° 30′
P on O	139° 15′
O on O	122° 34′

It is very common to find the edges between O and r truncated. The specific gravity varies from 1·5 to 1·7; the hardness from 2 to 2·5. When coloured it is of a light yellowish-green: the fracture is conchoidal and of a resinous lustre.

The chemical composition as given by Berzelius is—

Boracic Acid	36·52
Soda	16·37
Water	47·11

Boracite is in many respects one of the most interesting bodies of the inorganic kingdom. It was first described by Lasius in 1787 under the name of cubic quartz, and was found in the gypsum rocks near Lüneburg in Brunswick, where it occurs in small crystals, which are perfectly developed on every side and imbedded in the gypsum. The crystals usually present a combination of the cube, dodecahedron, and the two hemi-octohedrons, in which combinations sometimes the one sometimes the other form predominates. The locality was for some time the only spot where boracite was found, until the crystals were discovered in a gypsum rock called Segeberg in Holstein, at the foot of which is situated a small village of the same name. The crystals of the *Boracite* of this spot possess the same characters as those of Lüneburg, and add considerable interest to the very peculiar rock in which they are found, which is itself a very remarkable object from its abrupt elevation over the sandy plain of Holstein. It is described in the 'Geognostischen Aufsätzen' of Steffens, who considers it to be of the same formation as the gypsum of the Paris basin.

Boracite has been analysed by Stromeyer, who found it to be composed of boracic acid 67, magnesia 33. The specific gravity is 2·9; it is transparent, but also frequently opaque; the hardness is 6·5 to 7; it is brittle, and has a conchoidal fracture. The lustre is vitreous, inclining to adamantine. The colour is usually a yellowish or greenish gray.

It fuses easily before the blowpipe, at first with much foam, and then forms a glass globule, which crystallises on cooling, so that the surface is covered with fine acicular points. When just so much soda is added as will form with it a clear glass, it will then crystallise as perfectly as the phosphate of lead.

BORRERA, a genus of plants belonging to the natural order of *Lichens*, named by Acharius in honour of William Borrer, F.L.S., who has very successfully cultivated Cryptogamic Botany, especially that of Great Britain. One species *B. furfuracea* has the reputation of being astringent and febrifuge. A genus of Cinchonaceous plants has also been named after Mr. Borrer. [BORRERIA.]

BORRERIA, a genus of plants named in honour of William Borrer, F.L.S. It belongs to the natural order *Cinchonaceæ*, and has the following characters:—Calyx with an ovate tube, and a permanent limb which is parted into 2-4 teeth; corolla salver-shaped or funnel-shaped, 4-lobed; stamens 4, exserted or inclosed; stigma bifid or undivided; capsule crowned by the limb of the calyx, 2-celled, opening from the apex at the dissepiment when mature, but without any dissepiment; coccæ or nuts 1-seeded, opening by a longitudinal chink inside. The species, which are very numerous, are most of them herbs or undershrubs, and are nearly all natives of tropical America.

B. ferruginea, has a herbaceous, hard, erect, branched stem; tetragonal hairy branches; oblong, acute, obliquely 3-4-nerved leaves, scabrous above and pale beneath, and scabrous on the nerves from hairs; bristles of the stipules the length of the sheath; whorls of flowers globose, terminal, and axillary; capsule downy, crowned by the four subulate teeth of the calyx. This plant is a native of Brazil, in elevated pastures in the provinces of Minas Geraes and St. Paul. The plant is called Poaya, and Poaya da Maya at Cape Frio. This is one of the plants which yield a bastard ipecacuanha. The roots are of a brown colour, and when taken produce sickness and vomiting.

B. Poaya is glabrous, and has a herbaceous simple tetragonal stem; sessile oblong-elliptic acute leaves, obliquely 6-nerved on both sides of the midrib; the stipules cleft into many long bristles; whorls of flowers capitate, sessile, few, axillary, and a larger terminal one; lobes of calyx 4, lanceolate linear acute, longer than the ovarium; corolla smooth; anthers exserted. A native of Brazil in elevated pastures. It has blue flowers. The roots are white, and produce sickness when taken, and are consequently frequently substituted for ipecacuanha. The leaves when chewed have a sweet taste at first, and afterwards an acid one; a decoction of them is sometimes employed in the cure of colic. Upwards of 80 species of this genus have been described, of which only the above two appear to be used by man. They may be cultivated in this country in greenhouses. A light soil suits them best, and cuttings of the shrubby pieces readily strike root under a hand-glass in heat. The herbaceous species require the same treatment as other tender annuals.

(Don, *Gardener's Dictionary*.)

BOS. [BOVIDÆ.]

BO'STRICHUS (Latreille), a genus of Insects belonging to the order *Coleoptera*, of the family *Xylophagi*. Generic characters:—Body oblong, cylindrical, or nearly so; head rounded, capable of being retracted within the thorax as far as the eyes; eyes distinctly projecting; antennæ ten-jointed, short, the three terminal joints large and distinct, twice as broad as the remainder; the five following joints small and close together; the two remaining, or two basal joints, slightly thickened; palpi tolerably distinct, about equal in length to the mandibles, short, and three-jointed; thorax convex above, the anterior part humped; legs rather short, tarsi four-jointed, simple. The insects of this tribe are found on old trees, upon which their larvæ feed, and in so doing they generally construct their burrows under the bark.

Bostrichus capucinus (a rare species in this country) is about half an inch long; the head, antennæ, thorax, and legs are black; the rest of the body is red.

BOSWE'LLIA, a genus of balsamic plants belonging to the natural order *Amyridaceæ*. One of the species is believed by Colebrooke to be the *Λίβανος* of Theophrastus, and the *Thurea virga* of the Romans. ('Asiatic Researches,' vol. ix.)

It appears that the gum-resin called olibanum is the frankincense that was used by the ancients in their religious ceremonies. Linnæus was of opinion that it was yielded by the Lycian juniper; but that plant is a native of the south of France as well as of the Levant, and the botanists of that country deny that any such substance is produced by their juniper. The Greeks obtained their frankincense from Arabia. The Arabians call olibanum both Lubán and Cundur; but as benzoin is most used at the present day for religious purposes, the Mohammedan writers of India on Materia Medica apply only the term Cundur to olibanum. This Cundur has been ascertained by Messrs. Colebrooke, Hunter, and Roxburgh to be yielded by *Boswellia thurifera* or *B. serrata*. It is a large timber-tree found in the mountainous parts of India, yielding a most fragrant resin from wounds made in the bark. Its leaves are pinnate, and consist of about ten pairs of hairy serrated oblong leaflets, each of which is from an inch to an inch and a half in length. The flowers are pale pink, small, and numerous. The calyx is 5-lobed, the corolla of 5 downy petals, the disk a fleshy crenelled cup, and the stamens 10, alternately shorter. The fruit is a 3-sided, 3-valved, 3-celled capsule, containing a single-winged pendulous seed in each cell.

From this Roxburgh distinguishes as a different species *Boswellia glabra*, a plant also yielding a resin which is used for incense and as pitch in some parts of India. It differs from the last in having no hairs on its leaves, in its leaflets being often toothless, and in its flowers being panicled.

A substance analogous to olibanum, and used in a similar way in various parts of the world, is procured from several different trees, such as, in America, the *Croton nitens* (Schwartz), *C. thurifer* (Kunth), *C. adipatus* (Kunth): in Columbia, *Baillieria nervifolia* (Kunth) yields the American frankincense; the *Amyris* (*Icica Tacamahaca*, Kunth) *ambrosiaca* (Linn.), yields also the resin coumier, likewise called American frankincense.

Laëtia apetala (Jacq.) also yields a substance similar to frankincense.

Olibanum occurs in commerce of two kinds, the Arabian and East Indian. The former kind is now seldom met with, and its origin is a subject of doubt; the latter is obtained from the tree above described, and to it we limit our remarks. There are two varieties or degrees of fineness of it, the best called 'olibanum electrum,' or 'in granis,' sometimes called 'thus mannæ' or 'thus masculum': the other is termed 'olibanum commune,' or 'in sortis,' also 'fœmineum.' The first occurs in pieces varying from the size of a hazel-nut to that of a walnut, or larger, which are roundish or irregular in shape, of a light yellowish colour, varying to red or brown in some pieces, opaque or semi-transparent, the outside often covered with a white powder, and upon being pounded the whole becomes a white powder. It is very friable, and breaks with a dull, sometimes even, sometimes splintery fracture.

The second sort is generally in larger pieces, mostly of a dirty-gray or fawn-colour, and intermingled with pieces of wood and other impurities.

BOTANY is that branch of science which comprehends all that relates to the Vegetable Kingdom. The term Botany is derived from the Greek, in which βοτάνη signifies any kind of grass or herb, and βοτανική the art which teaches the nature of plants and herbs. The structure of plants, their mode of growth, their habits of life, their mutual relations, their uses to man or the danger that results from their employment, the station they occupy in the scale of the creation, and many other similar considerations, form each an extensive field of inquiry which botany combines into one connected whole.

Although the limits of the science of Botany can be easily defined to be the structure and functions of plants, it is not so easy to define the nature of a plant. It is true that with regard to the great mass of organic forms which belong to the vegetable kingdom there is no difficulty in at once assigning them their position, but there are a very large number of organised bodies that stand in such intimate relations with the animal kingdom as to create a perpetual difficulty with regard to their real nature. At the time when it was considered a sufficient distinction between plants and animals that the former were fixed and the latter had the power of locomotion, large orders of beings which are now classed with plants were regarded as animals. To some of these it may be interesting to draw attention, as it is amongst them that the naturalist is enabled to observe in its simplest forms the true nature of the functions of vegetable structure. It was in the large order *Algæ* [ALGÆ], to which belong the various forms of sea-weeds, and the lowest orders of plants inhabiting fresh-water, that those functions were first observed that were supposed to be peculiar to animals. Amongst the *Oscillatoriæ* it was found that a number had a distinct power of self-movement, so that as far as these were concerned it became evident that locomotion would not distinguish plants from animals. Many of the early observers with the microscope had also seen that the spores or cells that represented seeds in the higher plants had the power of motion. In order to distinguish between these movements and those possessed by the ova of animals, it was supposed that the latter had cilia whilst the former had not. Unger and Thuret however, in 1843, both announced the fact that the spores of many *Algæ* possess vibratile cilia, not to be distinguished from those on animal bodies. This important discovery has been followed by a very rigid examination of the various organised bodies admitted by Ehrenberg into the class of Animalcules, in his 'Infusionsthierchen,' on account of their locomotion by means of cilia. The consequence has been that large numbers of the *Infusoria* of Ehrenberg are now regarded as plants. One of the most remarkable of these is the *Volvox globator*, or Globe Animalcule, which, although endowed with cilia and possessing the most active powers of motion, has through the recent researches of Professor Williamson and Mr. Busk been shown to be an undoubted plant. Not only does the history of its development and its mode of reproduction bear out this conclusion, but also the presence of starch, detected by Mr. Busk during the growth of the young *Volvox* ('Microscopical Transactions,' vol. i. New Series). The placing this form in the vegetable kingdom is important, as a large number of the forms placed by Ehrenberg near *Volvox* must now be regarded also as plants. This serves to remove the anomaly which has sometimes been insisted on, that the lower animals perform the functions of the higher plants, that is, take up carbonic acid and throw out oxygen. The fact is, these lower animals are plants. [ANIMAL KINGDOM.]

Ehrenberg also describes and figures the families of *Diatomaceæ* and *Desmideæ* in his *Infusoria*. They have the power of movement but are destitute of cilia. The *Desmideæ* contain chlorophyle, are developed similar to the *Algæ*, and the fact of their conjugating after the manner of the *Zygnæmata* amongst the *Algæ*, first observed by Mr. Thwaites, has led naturalists to place them amongst plants. Mr. Ralfs, whose work on the 'British Desmideæ' is one of the best on the subject, states that he has found starch universally present amongst them. The *Diatomaceæ* are not so decidedly vegetable in their nature. Lindley in his 'Vegetable Kingdom,' however, admits *Diotomaceæ*, and regards *Desmideæ* as a sub-kingdom. The presence of a shell or frustule of silica, sometimes very complicated in its structure, has led Schleiden to reject the *Diatomaceæ* as plants, whilst Kützing admits some and rejects others. Their general resemblance to *Desmideæ* has given them their position in the vegetable kingdom.

On the other hand the Sponges (*Spongiadæ*), which were placed amongst animals on account of the active motile habits of their ova, seemed to be destined to classification again with plants when motility no longer became the distinguishing mark of the two kingdoms. There are, however, other points of structure which still induce the zoologist to lay claim to the sponges. The corallines (*Corallina*) which were formerly classed with the sponges, first as plants, then as animals, are now again placed with the *Ceramiaceæ* amongst the sea-weeds, and have a decided relation to the vegetable kingdom.

From these facts it is very evident that no mere technical definition will enable the naturalist to separate the animal and vegetable kingdoms, and that it is only by observing the structure and functions of organic beings through the whole course of their existence that we can hope to assign them their right position as plants or anim[illegible]

In [illegible]ermining the sphere of Botany by the inquiry into the nature of the plant, it will at once be seen that the study of plants cannot be successfully prosecuted without inquiry into the nature of animals. Again, the chemical elements of which plants and animals are formed, exert a great influence through their peculiar properties on the life of these beings. These must be always taken into consideration in speaking of the structure of a plant or the functions it performs. Hence we see that Botany is but the part of a great series of facts in which the inorganic elements, the cells of plants, and the cells of animals, are constantly taking a part.

In order to study Botany therefore successfully, the first knowledge that is necessary is that of the properties of the elements which enter into the composition of plants and animals. These are more especially four, carbon, hydrogen, oxygen, and nitrogen, which on account of their universal presence in plants and animals have been called organic or necessary elements. In addition to these are found twelve or thirteen other elements, which not being universally present may be called occasional or inorganic elements. Sulphur, phosphorus, calcium, potassium, sodium, iron, magnesium, iodine, bromine, silica, are the most conspicuous of these elements. The organic elements enter into various compounds which are found in plants, as sugar, starch, cellulose, protein, chlorophyle, gums, resins, alkaloids, acids, &c.; whose properties should be studied in order that their presence may be readily recognised in the dissection of plants. In order to accomplish this, re-agents must be employed, as iodine, potassa, sulphuric acid, iron, and many others, which on being applied to the parts of plants reveal by their action the nature of the vegetable compounds.

One of the most important aids to the study of the structure of plants, and by which the great recent progress in physiology has been made, is the microscope. The textures of plants as well as animals take their origin in cells so minute that they cannot be seen by the naked eye. It is in and around these cells that the active functions of every part of an animal or plant are going on; and it is only as the botanist gets to know the nature of the changes which the vegetable elements and their compounds undergo in the cells of plants, that he can comprehend the general laws of vegetable life. Not only is it necessary to the botanist to study these laws by the aid of the microscope, but the general physiologist and student of the functions of the human body will find it necessary to begin his inquiries by the study of the nature of vegetable cells. It was by following up the researches made by Schleiden on vegetable cells, that Schwann was enabled to demonstrate the cellular structure of the animal body, and thus to initiate a new era in physiology. It is still in the plant that the simplest condition of the cell is observed. It is also in the plant that the greatest chemical activity of the cell exists. The food of animals, and that which constitutes the substance of the tissues of animals, are all formed in the interior of the cells of plants. It is the cell of the plant which appropriates the carbonic acid of the atmosphere, and throws back again into it oxygen gas; on the one hand depriving it of an agent destructive to animal life, and on the other supplying the agent by which alone animal life could be carried on. It is also in the vegetable cell that the chemist must seek the solution of some of the most difficult problems of his science. The chemist cannot convert carbonic acid and ammonia into protein, sugar, starch, &c.—processes which are going on in every vegetable cell; he must therefore regard attentively the changes going on in the cells of plants, if he would manufacture the products of the vegetable kingdom independent of its aid.

Amongst the practical arts of life a knowledge of Botany is important to many. Agriculture and Horticulture are the two arts with which its relation is the most obvious; for although a considerable part of all the practices in each of them grew out of mere experience, or was discovered by chance, yet there is no possibility of improving them except by other fortunate accidents, or of advancing them at a more rapid rate, unless by the application of vegetable physiology. The world, especially that part of it to which these arts belong, is little accustomed to trace to their source the common practices with which it has been familiar from its infancy; and it is far from suspecting that many of the operations which are intrusted to the most ignorant rustics have one by one and piecemeal been hit upon during the careful study of nature by philosophers whose names it never heard. Gardening and Husbandry may be defined as the arts, firstly, of improving the quality of various useful plants, and secondly, of increasing the quantity which a given space of earth is capable of producing.

To improve the quality of any one plant, and to render it better adapted to the uses of mankind upon scientific principles, is a very complicated process, and is to be effected in many different ways, all of which require an intimate knowledge of the nature of the vital actions of plants, and of the degree in which they are affected by either external or internal causes. For example, a particular kind of flax produces fibres which are too coarse for the manufacturer; it is impossible to know how those delicate elementary tubes are to be rendered fine without being aware of the manner in which vegetable tissue is affected by light, air, and earth. The flavour of some fruit is too acid; it is the botanist only who could have discovered how to increase the quantity of saccharine matter. Potatoes are sometimes watery and unfit for food; we learn from vegetable physiology that this is often caused by the leaves not being sufficiently exposed to solar light, the great agent in causing the production of vegetable secretions. The leaves of the tea plant are harmless and only slightly stimulating in certain latitudes; they become narcotic and unwholesome in others; this apparent puzzle is explained by the connection that exists between climate and vegetation, a purely botanical question. Certain races of plants may exist, of which one is too vigorous, the other too debilitated for the purposes of the cultivator; the botanist shows how an intermediate race may be created, having the best qualites of both.

Certain vegetable productions are susceptible of being produced in particular latitudes, others are not, or not to any useful purpose: for instance, in England, on account of the want of the necessary heat at the period of ripening the grape, the vine will never yield grapes capable of making such wine as even that of champagne, nor will tobacco ever acquire that peculiar principle which gives it so great a value in tropical and subtropical climates when grown in other countries; and yet both these plants flourish in the soil of England. The botanist can explain the cause of this, and thus prevent the commencement of speculations which can never end except in loss and disappointment.

The quantity of produce which may be procured from a given space of ground varies very much according to the skill of the cultivator, but that skill is in reality the mere application of the rules of vegetable physiology to each particular case; an application that is most frequently made unconsciously, but which nevertheless is made. We are too apt to overlook causes in effects, and to ascribe the improvements we witness to a mere advance in art, without considering that that advance must have had a cause, and that the cause can only be the working of some master-hand which is afterwards blindly followed by the community. The crops of orchard-fruit are doubled and trebled in many places: old exhausted races are replaced by young, vigorous, and prolific ones; the cider and perry farmer will feel the benefit of this, but he will forget that he owes the change to the patient skill of a vegetable physiologist. The produce of the potato is augmented in the same proportion; twice at least the ordinary quantity of this important article of food may now be obtained from every field. The peasant will feel the additional comfort thus diffused around him, but he will never have heard of the name of Knight; nor will he know, after a few years, that the produce of the land was ever smaller.

Nor is it alone to articles of food that this science is to be applied. Next in importance to food are fire and shelter, both of which are mainly furnished by timber. The laws of nature which regulate the production of this substance are among the most curious in science: we possess the most absolute control over them; we hold in our very hands the means of regulating their action; and if we neglect them, as is too often the case, it is not science which is to blame, but those who undervalue and neglect her. Because trees will grow without assistance, and because in spite of neglect and ignorance timber is perpetually renewing itself upon the earth, we forget that either its rate of production may be accelerated or its quality improved. Instances are not wanting where plantations in this country made for particular purposes at a large expense have been totally ruined, with reference to the objects of those who planted them, from ignorance of the simplest laws of vegetable physiology.

Some allusion has already been made to the important results which arise out of the study of the connection between vegetation and climate. The quality of all vegetable productions is influenced essentially by external causes; intensity of light, atmospheric pressure, humidity, temperature, and seasons, are the great agents which modify the tissue, which control development, and which regulate the formation of sensible properties. Various combinations of these and other external causes are what constitute diversities of climate, and it is therefore obvious that the connection between the latter and vegetation is of the most intimate nature. But as this is a branch of the science of comparatively modern origin there are few instances of its application: one of the most striking was the declaration of Dr. Royle, that cotton might be obtained in the East Indies equal to the finest from America—a prophecy which has already been fulfilled, in consequence of the practical adoption of plans similar to those which he theoretically suggested. Can tea be cultivated as advantageously elsewhere as in China? Here is a single question of immense importance, involving the interests of millions of human beings, and affecting the pecuniary interests of Great Britain as much as any commercial problem ever did. This question has been answered by the botanist in the affirmative, and already the natives of the East Indies are supplied with tea from the Himalaya, and Asam tea may be bought in the shops of London.

To the medical man the study of botany is of the highest interest, as the members of the vegetable kingdom yield to him the most important means of his art. It is only as the properties of plants are studied that new agents for the alleviation of disease can be expected, or that substitutes for those already in use can be employed.

Thus far we have more especially referred to the study of vegetable physiology. Systematic Botany bears upon practice not less usefully, but in a different way. If the only advantage of classifying plants were to acquire the power of discovering their scientific names, even that would have a certain kind of interest, because it would ensure a uniformity of language in speaking of them; if it had the additional property of demonstrating the gradual connection that is discoverable between all the beings in the organised part of the creation, of proving that there is an insensible transition from one form of living matter to another without break or interruption, and of explaining in a clear and intelligible manner the nature of that universal harmony of which philosophers are used to talk, the interest and importance of botanical classifications would be still further enhanced; but the practical importance of them would still be extremely limited. It is only when we look to the coincidence between botanical affinities and sensible properties, and to the external indications of internal qualities, that we perceive the great features of its utility to man. If the qualities of every plant required to be ascertained by a circuitous and tedious series of experiments, no life could be long enough for the task, nor, if it were, could any memory however powerful remember so extensive a series of facts; and if under such circumstances botanists whose whole life is occupied in the study should be unable to master the difficulties, systematic botany could never be applied at all to any useful purpose, because it must of necessity be far beyond the acquirement of those persons who would be most likely to have occasion to employ it. But it was long since suspected that plants which agree with each other in organisation also agree in the secretions which may be supposed to be the result of that organisation. Linnæus, in his dissertation upon the properties of plants, declares that species of the same genus possess similar virtues, that those of the same natural order are near each other in properties, and that those which belong to the same natural class have also some relation to each other in their sensible properties. This doctrine is now admitted on all hands among men of science to be incontrovertible, and places the practical utility of systematic botany in the most striking light. Instead of endless experiments leading to multitudes of incongruous and isolated facts, the whole history of the medicinal or economical uses of the vegetable kingdom is reduced to a comparatively small number of general laws; and a student instead of being compelled to entangle himself in a maze of specific distinctions, is only obliged in practice to make himself acquainted with the more striking groups; and having accomplished this he is enabled to judge of the properties of a species he had never seen before, by what he knows of some other species to which it is related. Some idea of the extent to which this power of judging of plants à priori is practically useful may be formed from this—that supposing the vegetable kingdom to consist of 100,000 species arranged in 6000 or 7000 genera, the vast mass of characters required to distinguish them will be collected under about 300 heads, a knowledge of not more than two-thirds of which will be required for the purposes of the general observer. Thus the common hedge-mallow is a mucilaginous inert plant, whose woody tissue is tough enough to be manufactured into cordage; it has certain botanical characters, which are readily observed and remembered; and it belongs to a group of plants consisting of not fewer than 700 species. It is only necessary to understand the structure of the common mallow to recognise all the remainder of the group, and to be aware of their uses and properties; so that a person in a foreign country who finds a plant agreeing with the mallow in those marks by which the *Malvaceæ* are known, although he should never have seen or heard of the plant before, would immediately recognise it to be mucilaginous and inert, and would expect to find its vegetable fibre tough enough to be manufactured into cordage. It is this class of facts which alone can lead with any certainty to the discovery in one country of substitutes for the useful plants of another; it has shown the similarity between the violet roots of Europe and one of the kinds of ipecacuanha of South America; that the astringency of the alum-root of the United States finds a parallel in those of the geraniums of England; that madder has its representative in the Isle of France, cinchona in India, and that India-rubber trees exist in the east as well as in the west.

The artist also would confer an advantage on his art by the study of Botany. It is on account of the utter neglect of any attention to vegetable forms that in almost all objects of art where plants are introduced they are ridiculously wrong. Not only are these monstrous caricatures of the vegetable kingdom introduced upon our walls, carpets, plates, dishes, saucers, &c., but into many of the great works of art. Paintings strictly correct in regard to general outline and colour are filled up with botanical impossibilities. The plants of tropical climates are found flourishing in the forests of Great Britain, and an Assyrian monarch is surrounded with the vegetation of the New World. Such anomalies could not exist if the artist studied as attentively the structure of the vegetable kingdom as he does that of the human body.

The study of Botany may be divided and pursued under the following heads:—

1. The Chemistry of Plants, including a knowledge of the physical and chemical properties of the elements which enter into the composition of plants. [SECRETIONS, VEGETABLE.]

2. The Histology of Plants, including the facts connected with the origin of the vegetable cell, the various functions it performs, and its life in connection with others in the formation of organs. [CELL, VEGETABLE; TISSUES, VEGETABLE.]

3. The Morphology of Plants, embracing the history of the origin and growth of the individual organs of plants, and the relation of all forms of organs to one another, and the laws which regulate the changes which the same organ undergoes in the same and in different families of plants. [STAMEN; PISTIL; SEED; FLOWER; FRUIT; OVULE.]

4. The Organology of Plants, including the general phenomena of the entire life of the plant, and the consideration of the relations which animals bear to plants, and the way in which they take part in the great changes going on in the surface of the earth. [STEM; ROOT; LEAF.]

5. Systematic Botany, embracing the principles of classification and the arrangement of plants in groups according to their relations to each other. This department of botany has been only gradually developed. Under the heads of EXOGENS, ENDOGENS, and ACROGENS will be found in this work the subdivisions proposed by the most recent writers on systematic botany. In order however to facilitate the student in discovering the order to which any plant he may possess belongs, we give here an analysis of the orders contained in the ENGLISH CYCLOPÆDIA upon the plan followed by Dr. Lindley in his 'Vegetable Kingdom.'

Class, EXOGENS.

Sub-Class, POLYPETALÆ. (Petals not united).

I. Stamens more than 20 (Polyandrous).

A. Ovary wholly or partly inferior	
a. Stipules present	
1. Carpels more or less distinct or solitary	*Pomaceæ.* (*Rosaceæ.*)
2. Carpels combined	
Placentas central	
Leaves opposite	*Rhizophoraceæ.*
Leaves alternate	*Lecythidaceæ.*
Placentas on the side	*Homaliaceæ.*
b. Stipules absent	
1. Carpels more or less distinct	*Anonaceæ.*
2. Carpels united	
Placentas spread about	*Nymphæaceæ.*
Placentas on sides	
Petals definite, distinct	*Loasaceæ.*
Petals indefinite, confused	*Cactaceæ.*
Placentas in the centre	
Leaves dotted	
Ovary 1-celled	*Chamælauciaceæ.*
Ovary more than 1-celled	*Myrtaceæ.*
Leaves dotless	
Petals numerous	*Mesembryaceæ.*
Petals few	
Petals narrow	*Alangiaceæ.* (*Nyssaceæ.*)
Petals round	
Style 1	*Barringtoniaceæ.* (*Myrtaceæ.*)
Styles separate	*Philadelphaceæ.*
B. Ovary superior	
a. Stipules present	
1. Carpels more or less distinct or solitary	
Stamens hypogynous	
Carpel solitary	*Leguminosæ.*
Carpels 00	*Magnoliaceæ.*
Stamens perigynous	
Styles coming from apex of carpels	
Carpel 1	*Drupaceæ.* (*Rosaceæ*).
Carpels more than 1	*Rosaceæ.*
Styles coming from base of carpels	*Chrysobalanaceæ.*
2. Carpels united; placentas more than 1	
Placentas on the side (parietal)	
Leaves dotted, dots round	*Flacourtiaceæ.*
Leaves dotted, dots linear and round, mixed	*Samydaceæ.*
Placentas in the centre	
Calyx imbricated	
Flowers unisexual	*Euphorbiaceæ.*
Flowers hermaphrodite	
Ovary 1-celled; sepals 2	*Portulacaceæ.*
Ovary 2 or more celled	
Calyx double	*Chlænaceæ.*
Calyx single	*Cistaceæ.*
Calyx valvate	
Stamens monadelphous; anthers 2-celled	
Stamens columnar	*Sterculiaceæ.*
Stamens not columnar	*Byttneriaceæ.*
Stamens monadelphous; anthers 1-celled	*Malvaceæ.*
Stamens monadelphous; calyx irregular	*Dipteraceæ.*
Stamens distinct	*Tiliaceæ.*
b. Stipules absent	
1. Carpels more or less distinct or solitary	
Carpels immersed in a disk	*Nelumbiaceæ.*
Carpels not immersed	
Stamens perigynous	*Rosaceæ.*
Stamens hypogynous	
Embryo in a vitellus	*Cabombaceæ.*
Embryo naked, very minute	
Seeds with an aril	*Dilleniaceæ.*
Exarillate; albumen fleshy	
Flowers hermaphrodite	*Ranunculaceæ.*
Flowers unisexual	*Schizandraceæ.*
Exarillate; albumen ruminated	*Anonaceæ.*
Embryo nearly as long as seed	
Calyx much imbricated	
Fruit a legume	*Leguminosæ.*
Fruit not a legume	
Seeds smooth	*Hypericaceæ.*
Seeds hairy	*Reaumuriaceæ.*
Calyx little imbricated	
Fruit not a legume	*Anacardiaceæ.*
Fruit a legume	*Leguminosæ.*
2. Carpels united; placentas more than 1	
Placentas parietal, in lines	
Anthers versatile; juice watery	*Capparidaceæ.*
Anthers innate; juice milky	*Papaveraceæ.*
Placentas parietal, spread over the lining of the fruit	*Flacourtiaceæ.*
Placentas spread over dissepiments	*Nymphæaceæ.*
Placentas central	
Stigma broad and petaloid	*Sarraceniaceæ.*
Stigma simple	
Ovary 1-celled	*Portulacaceæ.*
Ovary many-celled	
Calyx much imbricated	
Leaves compound	*Rhizobolaceæ.*

- Leaves simple
  - Petals equal to sepals
    - Seeds few . *Clusiaceæ.*
    - Seeds numerous; petals flat . . *Marcgraaviaceæ.*
    - Seeds numerous; petals crumpled . *Cistaceæ.*
- Calyx little or not at all imbricated
  - Stamens perigynous; calyx tubular . *Lythraceæ.*
  - Stamens hypogynous; calyx many-leaved. *Humiriaceæ.*

II. Stamens fewer than 20 (Oligandrous).

- A. Ovary wholly or partly inferior
  - *a.* Stipules present
    - Placentas parietal . . . . . *Homaliaceæ.*
    - Placentas in the centre
      - Flowers unisexual . . . . *Begoniaceæ.*
      - Flowers hermaphrodite
        - Stamens opposite petals . . *Rhamnaceæ.*
        - Stamens alternate with petals
          - Leaves opposite . . . *Rhizophoraceæ.*
          - Leaves alternate . . . *Hamamelidaceæ.*
  - *b.* Stipules absent
    - Placentas parietal
      - Flowers unisexual . . . . *Cucurbitaceæ.*
      - Flowers hermaphrodite . . . *Grossulaceæ.*
    - Placentas in the centre
      - Flowers in umbels; styles 2 . . *Umbelliferæ.*
      - Flowers in umbels; styles 3 . . *Araliaceæ.*
      - Flowers not in umbels
        - Carpels solitary
          - Petals strap-shaped; stamens distinct . . . . *Alangiaceæ.* (*Nyssaceæ.*)
          - Petals very narrow; stamens growing on them . . *Loranthaceæ.*
          - Petals oblong; leaves hispid
            - Cotyledons convolute . *Combretaceæ.*
            - Cotyledons flat . . *Haloragaceæ.*
          - Petals oblong; leaves balsamic *Anacardiaceæ.*
        - Carpels divaricating
          - Leaves alternate: herbs . *Saxifragaceæ.*
          - Leaves opposite: shrubs . *Hydrangeaceæ.*
        - Carpels parallel, combined
          - Calyx valvate; petals opposite stamens . . . *Rhamnaceæ.*
          - Calyx valvate; petals alternate with stamens
            - Albumen none . . *Onagraceæ.*
            - Albumen copious . . *Cornaceæ.*
          - Calyx not valvate
            - Stamens doubled . . *Melastomaceæ.*
            - Stamens curved
              - Leaves dotted . . *Myrtaceæ.*
              - Leaves not dotted
                - Parts of flower 4
                  - Ovules ascending *Onagraceæ.*
                  - Ovules pendulous *Haloragaceæ.*
                - Parts of flower not 4; seeds many
                  - Leafy . . *Escallonaceæ.*
                  - Scaly . . *Monotropaceæ.*
                - Parts of flower not 4; seeds few . *Bruniaceæ.*
- B. Ovary wholly superior
  - *a.* Leaves stipulate
    - 1. Carpels distinct or solitary
      - Anthers with recurved valves . *Berberidaceæ.*
      - Anthers with longitudinal valves
        - Style from the base of the carpel *Chrysobalanaceæ.*
        - Style from apex of carpel; fruit a legume . . . *Leguminosæ.*
        - Style from apex of carpel; fruit a drupe or capsule . *Rosaceæ.*
    - 2. Carpels wholly combined
      - Placentas parietal
        - Flowers with appendages . *Passifloraceæ.*
        - Flowers without appendages
          - Leaves with round and oblong transparent dots . *Sanydaceæ.*
          - Leaves dotless, circinate when young . . *Droseraceæ.*
          - Leaves dotless, straight when young; fruit capsular . . . . *Violaceæ.*
          - Leaves dotless, straight when young; fruit siliquose . . . *Moringaceæ.*
      - Placentas central
        - Styles distinct
          - Calyx in a broken whorl . *Elatinaceæ.*
          - Calyx in a complete whorl
            - Flowers unisexual . *Euphorbiaceæ.*
            - Flowers hermaphrodite
              - Petals minute . *Illecebraceæ.*
              - Petals large; stamens hypogynous . . *Malpighiaceæ.*
              - Petals large; stamens perigynous; leaves opposite . . *Cunoniaceæ.*
              - Petals large; stamens perigynous; leaves alternate . . *Saxifragaceæ.*
          - Calyx valvate . . . *Tiliaceæ.*
        - Styles more or less combined, gynobasic
          - Gynobase fleshy . . *Ochnaceæ.*
          - Gynobase dry; leaves opposite . . . . *Zygophyllaceæ.*
          - Gynobase dry; leaves alternate
            - Fruit beaked . . *Geraniaceæ.*
            - Fruit not beaked . . *Oxalidaceæ.*
        - Styles more or less combined, not gynobasic
          - Calyx in a broken whorl
            - Flowers spurred . . *Vochyaceæ.*
            - Flowers not spurred, calyculate . . . *Chlænaceæ.*
            - Flowers not spurred, naked *Sapindaceæ.*
          - Calyx in a complete whorl
            - Leaves compound; sepals more than 2 . . *Staphyleaceæ.*
            - Leaves simple; sepals about 2 . . . *Malpighiaceæ.*
            - Leaves simple; sepals 2. *Portulacaceæ.*
          - Calyx valvate or open
            - Stamens columnar . *Sterculiaceæ.*
            - Stamens not columnar
              - Stamens opposite petals
                - Perigynous . . *Rhamnaceæ.*
                - Hypogynous . . *Vitaceæ.*
              - Stamens alternate with petals
                - Anthers porous . *Tiliaceæ.*
                - Anthers slit; petals split . . . *Chailletiaceæ.*
                - Anthers slit; petals undivided . . *Amyridaceæ.*
  - *b.* Stipules absent
    - 1. Carpels distinct or solitary
      - Anther-valves recurved. . . *Berberidaceæ.*
      - Anther-valves longitudinal
        - Fruit a legume; radicle next hilum . . . . . *Leguminosæ.*
        - Fruit a legume; radicle away from hilum . . . . *Connaraceæ.*
        - Fruit not leguminous
          - Carpels with 1 scale . . *Crassulaceæ.*
          - Carpels with two scales . *Francoaceæ.*
          - Carpels without scales
            - Albumen abundant; embryo minute
              - Flowers unisexual . *Lardizabalaceæ.*
              - Flowers hermaphrodite
                - Embryo in vitellus *Cabombaceæ.*
                - Embryo naked
                  - Albumen solid *Ranunculaceæ.*
                  - Albumen ruminate . *Anonaceæ.*
            - Albumen small or none
              - Carpels several
                - Enclosed . . *Calycanthaceæ.*
                - Naked . . *Menispermaceæ.*
              - Carpels solitary
                - Leaves dotted . *Amyridaceæ.*
                - Leaves dotless . *Anacardiaceæ.*
    - 2. Carpels combined into a solid pistil
      - Placentas parietal
        - Stamens tetradynamous . . *Cruciferæ.*

  - Stamens not tetradynamous
    - Flowers with sterile stamens
      - Stamens and pistils on distinct flowers
        - Pistil-flower crowned *Pangiaceæ.*
        - Pistil-flower not crowned . . *Papayaceæ.*
      - Stamens and pistils together; placentæ lining the fruit . . *Flacourtiaceæ.*
      - Stamens and pistils together; placentæ in rows . . . . *Malesherbiaceæ.*
    - Flowers without sterile stamens
      - Disk of flower large; stamens indefinite . *Capparidaceæ.*
      - Disk of flower large; stamens definite . *Resedaceæ.*
      - Disk of flower small or none
        - Albumen large . *Papaveraceæ.*
        - Albumen small
          - Calyx 5-leaved . *Turneraceæ.*
          - Calyx tubular . *Frankeniaceæ.*
- Placentas covering dissepiments . *Nymphæaceæ.*
- Placentas central
  - Styles distinct
    - Calyx valvate. . . . *Vivianaceæ.*
    - Calyx in a broken whorl
      - Seeds hairy . . . *Reaumuriaceæ.*
      - Seeds smooth; stamens polyadelphous . . *Hypericaceæ.*
      - Seeds smooth; stamens monadelphous, or free *Linaceæ.*
    - Calyx in a complete whorl
      - Carpels with a scale . *Crassulaceæ.*
      - Carpels without scales
        - Carpels divaricating . *Saxifragaceæ.*
        - Carpels not divaricating *Caryophyllaceæ.*
  - Styles united, gynobasic
    - Stamens arising from scales *Simarubaceæ.*
    - Stamens not arising from scales
      - Styles combined; flowers hermaphrodite . . *Rutaceæ.*
      - Styles combined; flowers unisexual . . . *Xanthoxylaceæ.*
      - Styles divided; flowers irregular . . . *Balsaminaceæ.*
  - Styles united, not gynobasic
    - Calyx in a broken whorl
      - Flowers symmetrical . *Clusiaceæ.*
      - Flowers unsymmetrical
        - Flowers regular
          - Petals without appendages . *Aceraceæ.*
          - Petals with appendages . . *Sapindaceæ.*
        - Flowers papilionaceous *Polygalaceæ.*
    - Calyx in a complete whorl
      - Carpels 4 or more; anthers porous
        - Embryo in the axis. *Ericaceæ.*
        - Embryo at the base *Pyrolaceæ.*
      - Carpels 4 or more; anthers slit
        - Seeds winged
          - Leafy . . . *Cedrelaceæ.*
          - Scaly . . . *Monotropaceæ.*
        - Seeds wingless
          - Stamens united . *Meliaceæ.*
          - Stamens free
            - Leaves dotted *Aurantiaceæ.*
            - Leaves dotless
              - Leafy . *Brexiaceæ.*
              - Scaly . *Monatropaceæ.*
      - Carpels fewer than 4
        - Flowers unisexual . *Empetraceæ.*
        - Flowers hermaphrodite
          - Sepals 2 . . *Portulacaceæ.*
          - Sepals above 2
            - Stamens hypogynous
              - Seeds comose . *Tamaricaceæ.*
              - Seeds naked
                - Ovules ascending . *Pittosporaceæ.*
                - Ovules pendulous . *Cyrillaceæ.*
            - Stamens perigynous
              - Ovules ascending. *Celastraceæ.*
              - Ovules suspended . *Bruniaceæ.*
    - Calyx valvate or open
      - Anthers porous . . *Tremandraceæ.*
      - Anthers slit
        - Stamens opposite petals . . . *Rhamnaceæ.*
        - Stamens alternate to petals
          - Leaves pinnate . *Amyridaceæ.*
          - Leaves simple; calyx tubular; stamens hypogynous . . *Olacaceæ.*
          - Leaves simple; calyx tubular; stamens perigynous . . *Lythraceæ.*

Sub-Class, MONOPETALÆ. (Petals united into a Tube).

I. Ovary superior.

- A. Flowers regular
  - *a.* 3- 4- 5-lobed
    - Leaves dotted . . . . . *Rutaceæ.*
    - Leaves dotless
      - Inflorescence gyrate . . . *Boraginaceæ.*
      - Inflorescence straight
        - Corolla plaited in æstivation . *Nolanaceæ.*
        - Corolla flat in æstivation . . *Stackhousiaceæ.*
  - *b.* Ovary not lobed
    - Carpels 4 or 5, or none
      - Anthers porous
        - Seeds winged . . . . *Pyrolaceæ.*
        - Seeds wingless
          - Anthers biporous. . . *Ericaceæ.*
          - Anthers uniporous . . *Epacridaceæ.*
      - Anthers slit
        - Stamens opposite petals
          - Shrubs. . . . . *Myrsinaceæ.*
          - Herbs . . . . . *Primulaceæ.*
        - Stamens not opposite petals
          - Seeds numerous
            - Carpels distinct . . *Crassulaceæ.*
            - Carpels combined . . *Monotropaceæ.*
          - Seeds few
            - Carpels distinct . . *Anonaceæ.*
            - Carpels combined
              - Ovules erect
                - Æstivation imbricate *Sapotaceæ.*
                - Æstivation plicate *Convolvulaceæ.*
              - Ovules pendulous
                - Number of stamens same as petals . *Aquifoliaceæ.*
                - Number of stamens double petals . *Ebenaceæ.*
    - Carpels usually 3
      - Inflorescence gyrate . . . *Hydrophyllaceæ.*
      - Inflorescence straight
        - Flowers unisexual . . . *Papayaceæ.*
        - Flowers hermaphrodite
          - An hypogynous disk . . *Polemoniaceæ.*
          - No hypogynous disk . . *Diapensiaceæ.*
    - Carpels 2
      - Stamens 2
        - Corolla valvate . . . . *Oleaceæ.*
        - Corolla imbricate . . . *Jasminaceæ.*
      - Stamens 4
        - Inflorescence gyrate
          - Fruit 1-celled . . . *Hydrophyllaceæ.*
          - Fruit 2-celled
            - Style bifid . . . *Ehretiaceæ.*
            - Style dichotomous . . *Cordiaceæ.*
        - Inflorescence straight
          - Calyx in a broken whorl
            - Leafy . . . . *Convolvulaceæ.*
            - Scaly . . . . *Cuscutaceæ.*
          - Calyx in a complete whorl
            - Flowers symmetrical
              - Carpels ⬭ . . *Solanaceæ.*

Carpels ()	
Anthers and stigma united .	*Asclepiadaceæ.*
Anthers and stigma separate	
Corolla imbricate .	*Gentianaceæ.*

Leaves opposite	
Stem square .	*Galiaceæ.*
Stem round .	*Caprifoliaceæ.*

Sub-Class, Apetalæ, or Incompletæ. (Without Petals, sometimes without Calyx.)

I. Without a Calyx (Achlamydeæ).

A. Stipules present	
Ovules numerous	*Balsamifluæ.*
Seeds winged	*Salicaceæ.*
Seeds comose	
Ovules solitary or very few	
Flowers with stamens and pistils	
Stamens unilateral	*Chloranthaceæ.*
Stamens whorled	*Saururaceæ.*
Flowers unisexual	
Carpel solitary ; ovules erect .	*Myricaceæ.*
Carpel solitary ; ovules pendulous	*Platanaceæ.*
Carpels tricoccous . . .	*Euphorbiaceæ.*
B. Stipules absent	
Ovules very numerous	*Podostemaceæ.*
Ovules single or few	
Flowers hermaphrodite	
Embryo in vitellus	*Piperaceæ.*
Embryo without vitellus . . .	*Oleaceæ.*
Flowers unisexual	
Flowers naked ; carpel single . .	*Myricaceæ.*
Flowers naked ; carpel double . .	*Callitrichaceæ.*
Flowers covered ; anther-valves recurved	*Atherospermaceæ.* (*Calycanthaceæ.*)
Flowers covered ; anther-valves slit .	*Monimiaceæ.*

II. Calyx present (Monochlamydæ).

A. Ovary inferior	
a. Stipules present	
Flowers with stamens and pistils .	*Aristolochiaceæ.*
Flowers unisexual ; fruit in a cup .	*Corylaceæ.*
Flowers unisexual ; fruit naked	
Many-seeded	*Begoniaceæ.*
1-seeded	*Artocarpaceæ.*
b. Stipules absent	
Flowers unisexual, in catkins	
Leaves simple, alternate . . .	*Myricaceæ.*
Leaves simple, opposite . . .	*Garryaceæ.*
Leaves compound	*Juglandaceæ.*
Flowers unisexual, not in catkins	
Seeds in a pulp	*Cucurbitaceæ.*
Seeds dry	
Numerous	*Datiscaceæ.*
Solitary	*Helwingiaceæ.*
Flowers hermaphrodite	
Leaves dotted	*Myrtaceæ.*
Leaves not dotted	
Ovary 3- 6-celled . . .	*Aristolochiaceæ.*
Ovary 1-celled	
Embryo straight ; cotyledons convoluted . . .	*Combretaceæ.*
Embryo straight ; cotyledons flat	
Albumen absent . .	*Haloragaceæ.*
Albumen fleshy . .	*Santalaceæ.*
Embryo curved . . .	*Chenopodiaceæ.*
Ovary 1-celled ; anthers many-celled	*Loranthaceæ.*
Ovary more than 1, but not 3 or 6-celled	
Embryo straight . . .	*Haloragaceæ.*
Embryo curved . . .	*Tetragoniaceæ.*
B. Ovary superior	
a. Stipules absent	
Flowers hermaphrodite	
Sepals 2	*Portulacaceæ.*
Sepals more than 2	
Carpels several, united	
Placentas parietal, in lines .	*Papaveraceæ.*
Placentas parietal, diffused .	*Flacourtiaceæ.*
Placentas in centre	
Ovules few	
Calyx short, with a gynobase . . .	*Rutaceæ.*
Calyx short, no gynobase	
Embryo curved .	*Phytolaccaceæ.*
Embryo straight .	*Celastraceæ.*
Calyx tubular . .	*Penæaceæ.*
Ovules numerous	
Carpels 2, divaricating	*Saxifragaceæ.*
Carpels not divaricating ; stamens hypogynous	
Leaves opposite .	*Caryophyllaceæ.*
Leaves alternate .	*Podostemaceæ.*
Carpels not divaricating ; stamens perigynous	
Fruit 1-celled .	*Primulaceæ.*
Fruit many-celled .	*Lythraceæ.*
Carpels solitary or separate	
Carpels several .	*Ranunculaceæ.*
Carpel single	
Anther - valves recurved, leafy	*Lauraceæ.*

- Anther-valves recurved, scaly . . . *Cassythaceæ.*
- Anther-valves slit
  - Fruit a legume . . . *Leguminosæ.*
  - Fruit not a legume
    - Calyx long or tubular
      - Base hardened . . . *Nyctaginaceæ.*
      - Tube hardened . . . *Scleranthaceæ.*
      - Not hardened
        - Stamens embedded in sepals . . . *Proteaceæ.*
        - Stamens not so
          - Ovules erect . . . *Elæagnaceæ.*
          - Ovules pendulous
            - Fruit 2-valved . . . *Aquilariaceæ.*
            - Fruit indehiscent . . . *Thymelaceæ.*
    - Calyx short
      - Leaves with scales . . . *Elæagnaceæ.*
      - Leaves dotted . . . *Amyridaceæ.*
      - Leaves smooth
        - Flowers in involucels . . . *Polygonaceæ.*
        - Flowers naked
          - Calyx dry . . . *Amarantaceæ.*
          - Calyx herbaceous
            - Stamens hypogynous . . . *Chenopodiaceæ.*
            - Stamens perigynous . . . *Basellaceæ.* (*Chenopodiaceæ.*)

- Flowers unisexual
  - Carpels several, united
    - Ovules numerous
      - Stamens columnar . . . *Nepenthaceæ.*
    - Ovules few
      - Leaves alternate
        - Dotted . . . *Xanthoxylaceæ.*
        - Not dotted . . . *Euphorbiaceæ.*
  - Carpel solitary
    - Calyx tubular . . . *Myristicaceæ.*
    - Calyx open
      - Carpels several . . . *Menispermaceæ.*
      - Carpel solitary
        - Embryo straight . . . *Casuarinaceæ.*
        - Embryo curved . . . *Chenopodiaceæ.*

- *b.* Stipules present
  - Flowers hermaphrodite
    - Sepals 2 . . . *Portulacaceæ.*
    - Sepals more than 2
      - Carpels several, united
        - Stamens hypogynous
          - Placentas parietal . . . *Flacourtiaceæ.*
          - Placentas central
            - Calyx valvate; stamens monadelphous
              - Partly sterile . . . *Byttneriaceæ.*
              - All fertile . . . *Sterculiaceæ.*
            - Calyx valvate; stamens distinct . . . *Tiliaceæ.*
            - Calyx imbricated
              - Fruit beaked . . . *Geraniaceæ.*
              - Not beaked . . . *Malpighiaceæ.*
        - Stamens perigynous
          - Placentas parietal . . . *Passifloraceæ.*
          - Placentas central
            - Leaves opposite . . . *Cunoniaceæ.*
            - Leaves alternate
              - Stamens alternate to sepals . . . *Rhamnaceæ.*
              - Calyx membranous . . . *Ulmaceæ.*
      - Carpels solitary or separate
        - Calyx membranous . . . *Illecebraceæ.*
        - Calyx herbaceous
          - Styles basal . . . *Chrysobalanaceæ.*
          - Styles terminal, 1 to an ovary
            - Fruit a legume . . . *Leguminosæ.*
            - Fruit not a legume . . . *Sanguisorbaceæ.*
          - Styles terminal, 3 to an ovary
            - Stipules ochreate . . . *Polygonaceæ.*
            - Stipules simple . . . *Phytolaccaceæ.*
  - Flowers unisexual
    - Carpels several, united
      - Flowers in catkins
        - Aril present . . . *Scepaceæ.*
        - No aril . . . *Betulaceæ.*
          - Seeds numerous . . . *Lacistemaceæ.*
      - Flowers not in catkins . . . *Euphorbiaceæ.*

Sub-Class, GYMNOGENS (Lindley).

- Stem jointed . . . *Gnetaceæ.*
- Stem continuous
  - Leaves pinnate . . . *Cycadaceæ.*
  - Leaves simple
    - Ovules in cones . . . *Pinaceæ.* (*Coniferæ.*)
    - Ovules solitary . . . *Taxaceæ.*

Class, ENDOGENS.

I. Flowers complete (having distinct Floral Envelopes).

- A. Ovary inferior
  - Flowers gynandrous . . . *Orchidaceæ.*
  - Flowers not gynandrous
    - Veins of leaves diverging from the midrib
      - Anther 1, with 1 cell . . . *Marantaceæ.*
      - Anther 1, with 2 cells . . . *Zingiberaceæ.*
      - Anthers 5 or 6 . . . *Musaceæ.*
    - Veins of leaves parallel with midribs
      - Stamens 3
        - Anthers turned outwards . . . *Iridaceæ.*
        - Anthers turned inwards . . . *Burmanniaceæ.*
      - Stamens 6
        - Leaves flat
          - Fruit 3-celled; sepals corolla-like
            - Radicle remote from hilum . . . *Hypoxidaceæ.*
            - Radicle next hilum . . . *Amaryllidaceæ.*
          - Fruit 3-celled; sepals calycine . . . *Bromeliaceæ.*
          - Fruit 1-celled . . . *Taccaceæ.*
        - Leaves equitant . . . *Hæmodoraceæ.*
      - Stamens more than 6 . . . *Hydrocharaceæ.*
- B. Ovary superior
  - Sepals calyx-like or glumaceous
    - Carpels separate, more or less
      - Placentas diffused . . . *Butomaceæ.*
      - Placentas narrow . . . *Alismaceæ.*
    - Carpels in a solid pistil
      - Petals distinct from calyx
        - Placentas central . . . *Commelinaceæ.*
        - Placentas parietal . . . *Mayaceæ.*
      - Petals not distinct from calyx
        - Flowers scattered . . . *Juncaceæ.*
        - Flowers spadicose . . . *Orontiaceæ.*
  - Sepals corolla-like
    - Carpels more or less separate
      - Seed solitary . . . *Palmaceæ.*
      - Seeds numerous
        - Anthers turned outwards . . . *Melanthaceæ.*
        - Anthers turned inwards
          - Parts of flower 6 . . . *Butomaceæ.*
          - Parts of flower 2 . . . *Philydraceæ.*
    - Carpels combined
      - Petals rolled inwards . . . *Pontederaceæ.*
      - Petals not rolled inwards
        - Flowers with appendages . . . *Gilliesiaceæ.*
        - Flowers without appendages . . . *Liliaceæ.*

II. Flowers incomplete (Floral Envelopes not distinct).

- A. Flowers in glumes
  - Stems hollow . . . *Graminaceæ.*
  - Stems solid
    - Carpel solitary; seed erect . . . *Cyperaceæ.*
    - Carpel solitary; seed pendulous . . . *Restiaceæ.*
    - Carpels several, distinct
      - Glumes only . . . *Desvauxiaceæ.*

Cup within glumes	*Eriocaulaceæ.*
Carpels several, combined	
Placentas parietal	*Xyridaceæ.*
Placentas central	*Restiaceæ.*
B. Flowers, or with a few verticillate leaves	
a. Flowers on a spadix	
Fruit a drupe	*Pandanaceæ.*
Fruit berried; leaves in bud, convolute	*Araceæ.*
Fruit dry; anthers clavate, on weak filaments	*Typhaceæ.*
b. Flowers not on a spadix	
Aquatic, with pendulous ovules	
Pollen globose	*Naiadaceæ.*
Pollen confervoid	*Zosteraceæ.*
Terrestrial; ovules erect . . .	*Juncaginaceæ.*
Aquatic; ovules erect	*Pistiaceæ.*

Sub-Class RHIZOGENS (Rhizanthæ).

Ovules indefinite	
Anthers opening by slits	*Cytinaceæ.*
Anthers bursting by pores	*Rafflesiaceæ.*
Ovules solitary	*Balanophoraceæ.*

Class, ACROGENS.

I. With Stems.

A. No distinct axis of growth	
Spores without elaters	*Ricciaceæ.*
Spores with elaters	
Spore-case with valves	*Jungermanniaceæ.*
Spore-case valveless	*Marchantiaceæ.*
B. A distinct axis of growth	
Spores with elaters	
Spore-case with valves	*Jungermanniaceæ.*
Spore-case in cones	*Equisetaceæ.*
Spores without elaters	
Spore-case on fronds	
Ringed	*Polypodiaceæ.*
Ringless	*Danæaceæ.*
Spore-case on edge of frond . . .	*Ophioglossaceæ.*
Spore-case in an involucre . . .	*Marsileaceæ.*
Spore-case naked	
Sessile in the axil of frond .	*Lycopodiaceæ.*
Stalked	
Valves	*Andræaceæ.* (*Musci.*)
Without valves	*Bryaceæ.* (*Musci.*)

II. Without Stems.

Mycelium present	
Spores in fours	
Hymenium naked	*Agaricaceæ.* (*Fungi.*)
Hymenium inclosed	*Lycoperdaceæ.*
Spore-case single	
Sporules naked	
Thallus obsolete	*Uredinaceæ.*
Thallus floccose	*Botrytaceæ.*
Sporules inclosed	
In asci	*Helvellaceæ.*
In a veil	*Mucoraceæ.*
Mycelium absent	
Aquatic	
Crystalline	*Diatomaceæ.*
Cellular or membranous	
Fresh-water chiefly	
Multiplied by zoospores . .	*Confervaceæ.*
Multiplied by spiral nucules . .	*Characeæ.*
Salt-water	
Multiplied by simple spores . .	*Fucaceæ.*
Multiplied by tetraspores . .	*Ceramiaceæ.*
Terrestrial	
Spores naked	*Graphidaceæ.*
Spores in asci	
Thallus gelatinous	*Collemaceæ.*
Thallus pulverulent	*Parmeliaceæ.*

It will be seen that many of the orders are repeated in this analysis under different divisions; and this arises from the fact that this analysis is artificial, and only expresses the general characters of each order. Besides this, in the strongest orders, exceptions to some very general points of structure frequently occur. Thus we have apetalous and irregular-flowered plants in the polypetalous regular-flowered order *Ranunculaceæ*. With a little practice such an analysis as the foregoing will enable any one acquainted with the structure of plants to refer any particular plant to its right order, and on turning to the order in the alphabetical part of this work he will find a detailed account of its structure and properties.

Before concluding this general article it may not be uninteresting just to glance at the steps by which the Science of Botany, more particularly the systematic department, has attained its present position. In doing this we shall confine ourselves to a mere sketch of the progress that has been made in elucidating the great principles of Botany by which its rank as a branch of philosophy is to be determined.

It is obvious, from various passages in the most ancient writers, that the art of distinguishing certain plants having medical virtues was taught at the earliest period of which we have any written record; and that the cultivation of something more than corn was already understood in the Homeric days, is sufficiently attested by the references to the vineyards of Laërtes and the gardens of Alcinous, and by the employment assigned to Lycaon, the son of Priam, of pruning figs in his father's garden.

The earliest tangible evidence that we possess of the real state of knowledge upon this subject is afforded by the remains of the writings of Aristotle and his school. From the absurd superstitions of the root-cutters (*rhizotomi*) of this period, it might be imagined that at this time botany was far from having any real existence; for it is to them that we have to trace the belief in the necessity of magical ceremonies and personal purification or preparation in collecting herbs: some sorts they tell us are to be cut against the wind, others after the body of the rhizotomist has been well oiled, some at night, some by day. Alliaceous food was a necessary preparation for procuring this herb, a draught of wine for that, and so on. But in fact at this very time the Peripatetic philosophers were in possession of a considerable mass of correct information concerning the nature of vegetable life, mixed up indeed with much that was fanciful and hypothetical, but calculated to give us a high opinion of their acuteness and of the amount of positive knowledge upon such subjects which had by that time been collected. It is by this school that botany must be considered to have been first formed into a science. Aristotle, in all probability, was its founder; for it is obvious, from the remarks upon plants scattered through his books concerning animals, that his knowledge of vegetable physiology was for his day of a most remarkable kind. But as the books immediately concerning plants ascribed to this philosopher are undoubted forgeries, it will be more convenient to take the works of Theophrastus as our principal guide to a determination of the state of botany at the commencement of this—

The First Era.—At the time when Theophrastus succeeded to the the chair of Aristotle (B.C. 324) no idea seems to have existed of classification, nor indeed was its necessity by any means apparent, for Theophrastus does not appear to have been acquainted with above 355 plants in all. In the application of their names, even to these, there was so much uncertainty, that the labours of commentators must be to a great extent bestowed in vain in endeavouring to elucidate them: for instance, Sprengel asserts that the name Aphake is applied indifferently to the dandelion and to a kind of vetch (*Lathyrus aphaca*), and Scorpios to a species of broom, to *Arnica Scorpioides*, and to a kind of ranunculus. But while Theophrastus was thus careless in his denominations of species, he has the great credit of having attended accurately to differences in the organs of plants, to some of which he gave new and special names; the form of leaves, their margin, the manner of their indentation, and the nature of the leaf-stalk, especially attracted his attention. He distinguished naked-seeded from capsular plants, and he demonstrated the absence of all philosophical distinction between trees, shrubs, and herbs, for he saw that myrtle-trees would degenerate into shrubs, and certain oleraceous plants become arborescent. Cellular tissue is spoken of as a sort of flesh interposed between the woody tissue or vegetable fibre; and even spiral vessels appear to be indicated under the name of *Ives*; leaves are correctly said to have their veins composed both of woody tissue and spiral vessels, and the parallelism of the veins of grasses is particularly pointed out; palm-wood is shown to be extremely different from that of trees with concentric layers; bark is correctly divided into liber and cortical integument, and the loss of the former is said to be usually destructive of life. The nutritive properties of leaves are clearly pointed out, and the power which both surfaces possess of absorbing atmospheric nourishment. Some notion appears to have existed of the sexes of plants, contrary to the opinion of Aristotle, who denied them to the vegetable kingdom. In particular Theophrastus speaks of the necessity of bringing the male dates into contact with the females, a fact which had been stated quite as clearly by Herodotus (i. 193) 100 years before; but it is plain that he had no correct idea upon this subject, for in another place he compares the male catkins of the hazel to the galls of the Kermes oak.

These points are abundantly sufficient to show that among the Peripatetics a considerable amount of tolerably exact knowledge of botany really existed, and that a solid foundation had been laid for their successors.

And in fact it appears that the impulse they gave to investigation did for some considerable time afterwards produce a perceptible effect; for by the time of Pliny it is evident that a considerable addition had been made to the stock of botanical knowledge. It is true that it was much disfigured by the poets, who then as now appear to have had only a smattering of the science of their day.; but it is incredible that they should have been able to glean that smattering out of any other field than a very rich one. For example, the sexuality of plants, which Aristotle had denied, which Theophrastus had adverted to, is spoken of in positive terms; grafting, in more ways than one, and even budding, are spoken of in language which is remarkably precise for the words of a poet; and although to these operations were attributed powers which they did not possess, yet it is abundantly plain that the processes were thoroughly understood. The

> "Angustus in ipso
> Fit nodo sinus; huc aliena ex arbore germen
> Includunt udoque docent inolescere libro,"

is as correct a description of the operation called budding as any modern could give in so many words; and it is impossible that such an operation should ever have been devised without a much more large and accurate knowledge of vegetable physiology than it is generally believed that the ancients possessed.

From this time forward all inquiry into matters of science began to decline. Under the later Roman emperors science became gradually extinguished; under the Byzantine princes it can scarcely be said to have been preserved; and the little attention it subsequently received from a few obscure writers rather hastened than arrested its downfall.

Upon the revival of science in Europe the writings of the classical and Arabian herbalists were taken as the text-books of the schools, but their errors were multiplied by false translations, their superstitions were admitted without question; and so little was added by the monkish authors, that between the time of Ebn Beithar, who flourished in the 13th century, and the year 1532, when the 'Herbarum Vivæ Eicones' of Otho Brunsfels, a Bernese physician, made their appearance, scarcely a single addition had been made to the slender stock of knowledge of about 1400 species, which are computed by Sprengel to have formed the total amount discovered by all botanists, Greek, Roman, and Arabian, up to the death of Abdallatif of Baghdad. Brunsfels describes the state of botany as being in his day most deplorable, as being principally in the hands of the most ignorant persons, and as consisting of a farrago of long and idle commentaries, disfigured "by myriads of barbarous, obsolete, and ridiculous names." He deserves to be mentioned as the first reformer in this science, and as the earliest writer who earnestly endeavoured to purify the corrupted streams which had flowed through so many ages of barbarism from the ancient Greek and Roman fountains. His example was speedily followed by Tragus, Fuchsius, Matthiolus, and others. The knowledge of species rapidly augmented, partly by the examination of indigenous plants and partly by the remarks of the earlier travellers, who about the year 1460 began to turn their attention to the vegetable kingdom; till at last their abundance became so great as to call for the assistance of compilers capable of digesting what had already begun to be scattered through numberless works. The first undertaking of the kind was by Conrad Gesner, a native of Zürich, who died in the year 1565. This excellent man spent the latter part of his life in collecting materials for a general history of plants. He is stated to have caused above 1500 drawings to be prepared for the illustration of his undertaking, but unfortunately he died before his project was executed, and his materials were afterwards dispersed. He appears however to have brought about one most important change in science, by discovering that the distinctions and true nature of plants were to be sought in their organs of reproduction rather than in those of nutrition. This was assuredly the first step that had been taken forward in the science since the fall of the Roman empire, and is abundant evidence of the great superiority of Gesner over all those who had preceded him. From this time collections of species were made by numerous writers; our countryman Turner, Dodoens, Lobel, Clusius Cæsalpinus, and the Bauhins, were the most distinguished writers between the years 1550 and 1600; and among them the number of known species was so exceedingly increased, especially by the discoveries of Clusius, that it became impossible to reduce them into any order without the adoption of some principle of classification. Hence originated the first attempts at systematical arrangement with which commences

The Second Era.—It is to Matthew Lobel, a Dutch physician residing in England in the time of Elizabeth, that the honour is to be ascribed of having been the first to strike out a method by which plants could be so arranged, that those which are most alike should be placed next to each other, or in other words, which should be an expression of their natural relations. As may be supposed this early attempt at the discovery of a natural system was exceedingly rude and imperfect; it is however remarkable for having comprehended several combinations which are recognised at the present day: *Cucurbitaceæ, Stellatæ, Gramineæ, Labiatæ, Boragineæ, Leguminosæ, Filices*, were all distinctly indicated; and it may be added, that under the name of *Asphodels* he grouped the principal part of modern petaloid monocotyledons. The reasons however why such groups were constituted were not then susceptible of definition; the true principles of classification had to be elicited by the long and patient study of succeeding ages. Among the foremost to take up this important subject was Cæsalpinus, a Roman physician attached to the court of Pope Sixtus V. This naturalist possessed a degree of insight into the science far beyond that of his age, and is memorable for the justness with which he appreciated many of the less obvious circumstances which his predecessors had overlooked. For example, he was aware of the circulation of the sap: he believed that its ascent from the roots was caused by heat; he knew that leaves are cortical expansions traversed by veins proceeding in part from the liber; he estimated the pith of plants at its true value, and seeds he compared to eggs, in which there exists a vital principle without life; but he denied the existence of sexes in the vegetable kingdom. Improving upon the views of Gesner, he showed how great is the value of the fructification in systematic botany; the flower he said was nothing but the wrapper of the fruit; the essential part of the seed he considered to be what is called the corculum, that is, the double cone of plumule and radicle which connects the cotyledons. In general his views of vegetable physiology were much more just than those of his predecessors, and if he did not avoid the error of supposing certain plants to be mere abortions of more perfect species, as many grasses of corn, he amply redeemed his fame by the correction of other mistakes. From differences in the fruit and the seed of plants he formed a system which, though purely artificial and never much employed, had the merit of calling attention strongly to the existence of a class of important characters which had previously been either overlooked or undervalued.

But notwithstanding the attempts thus made by a few distinguished men to elevate the science to a higher station, and to reduce it to some general principles, it still continued to languish and to remain for the most part in the hands of the most ignorant pretenders, and in no country more so than in England. We find upon the authority of the celebrated Ray, that in this country in the middle of the 17th century it was in the most lamentable state. At that time the standard book of English botanists was a publication called Gerarde's 'Herbal,' which was, as Ray tells us, the production of a man almost entirely ignorant of the learned languages, in which nevertheless all books on science were at that time written. The principal part of the work was pirated from the 'Pemptades' of Dodoens, turned into English by one Priest, and in order to conceal the plunder the arrangement of Dodoens was exchanged for that of Lobel, while the whole was made up with the wood-blocks of Tabernæmontanus's 'Kräuterbuch,' often unskilfully transposed and confounded. At last a change as sudden as it was important was produced in the science by the application of the microscope to botanical purposes.

The Third Era.—About the middle of the 17th century this instrument was first employed in the examination of the elementary organs of plants, about which nothing had been previously learned since the time of Theophrastus. The discovery of spiral vessels by Henshaw in 1661, the examination of the cellular tissue by Hook at a somewhat later date, at once excited the attention of observers and led at nearly the same time to the appearance of two works upon vegetable anatomy, which at once so nearly exhausted the subject that it can scarcely be said to have again advanced till the beginning of the present century. Grew and Malpighi, the writers here adverted to, but more especially the former, combined with rare powers of observation a degree of patience which few men have ever possessed. They each examined the anatomy of vegetation in its minutest details, the former principally in the abstract, the latter more comparatively with the animal kingdom. Various forms of cellular tissue, intercellular passages, spiral vessels, woody tubes, ducts, the nature of hairs, the true structure of wood, were made at once familiar to the botanist; the real nature of sexes in plants was demonstrated; and it is quite surprising to look back on those days from the present high ground on which botany has taken its stand, and to see how little the views of Grew at least have subsequently required correction. From him physiological botany properly speaking took its origin. Clear and distinct ideas of the true causes of vegetable phenomena gradually arose out of a consideration of the physical properties of the minute parts through whose combined action they are brought about; and a solid foundation was laid for the theories of vegetation which subsequent botanists have propounded: to Grew may also be ascribed the honour of having first pointed out the important difference between seeds with one cotyledon and those with two, and of having thus been the discoverer of the two great natural classes into which the flowering part of the vegetable kingdom is now divided. Grew however was no systematist; it was reserved for another Englishman to discover the true principles of classification, and thus to commence

The Fourth Era.—John Ray, a man of capacious mind, of singular powers of observation and of extensive learning, driven from his collegiate employments by the infamous commands of a profligate prince, sought consolation in the study of natural history, to which he had been attached from his youth. Botany he found was fast settling back into the chaos of the middle ages, partly beneath the weight of undigested materials, but more from the want of some fixed principles by which the knowledge of the day should be methodised. Profiting by the discoveries of Grew and the other vegetable anatomists, to which he added a great store of original observation, he in his 'Historia Plantarum,' the first volume of which appeared in 1686, embodied in one connected series all the facts that had been collected concerning the structure and functions of plants: to these he added an exposition of what he considered the philosophy of classification, as indicated partly by human reason and partly by experience; and from the whole he deduced a classification which is unquestionably the basis of that which, under the name of the system of Jussieu, is everywhere recognised at the present day. For proofs of this we refer to the memoir of Ray in the Hist., Biog., &c. Division. We will only observe here that he separated flowering from flowerless plants; that he divided the former into monocotyledons and dicotyledons, and that under these three heads he arranged a considerable number of groups, partly his own, partly taken from Lobel and others; which are substantially the same as what are received by botanists of the present day under the name of natural orders. It is singular enough that the merits of this arrangement of John Ray should have been so little appreciated by his contemporaries and immediate successors as to have been but little adopted; and that instead of endeavouring to correct its errors and to remove its imperfections, botanists occupied themselves for several succeeding years in attempts at discovering other systems, the greater part of which were abandoned almost as soon as they were made known. Rivinus, Magnol, Tournefort, and Linnæus were the most celebrated of these writers; but the two last alone have had any permanent reputation. Tournefort, who for a long time stood at the head of the French school of botany, proposed in 1694 a method of arrangement, in its principles entirely artificial, but which in some cases was accidentally in accordance with natural affinities. It was founded chiefly upon differences in the corolla, without the slightest reference to physiological peculiarities; and is now forgotten, except in consequence of its having furnished some useful ideas to Jussieu, as will be hereafter shown.

The Fifth Era.—Linnæus was a genius of a different and a higher order. Educated in the severe school of adversity, accustomed from his earliest youth to estimate higher than all other things verbal accuracy and a logical precision, which are often most seductive when least applicable; endowed by nature with a most brilliant understanding, and capable, from constitutional strength, of any fatigue either of mind or body, this extraordinary man was destined to produce a revolution in botany, among other branches of natural history, which in some respects advanced and in others retarded its progress far more than the acts of any one who had preceded him. He found the phraseology bad, and he improved it; the nomenclature was awkward and inconvenient, he simplified it; the distinctions of genera and species, however much the former had been improved by Tournefort, were vague and too often empirical—he defined them with an apparent rigour which the world thought admirable, but which nature spurned; he found the classifications of his day so vague and uncertain that no two persons were agreed as to their value, and for them he substituted a scheme of the most specious aspect, in which all things seemed as clearly circumscribed by rule and line as the fields in the map of an estate; he fancied he had gained the mastery over nature, that he had discovered a mighty spell that would bind her down to be dissected and anatomised, and the world believed him; in short, he seized upon all the wardrobe of creation, and his followers never doubted that the bodiless puppets which he set in action were really the divine soul and essence of the organic world. Such was Linnæus, the mighty spirit of his day. Let us do this great man that justice which exaggeration on the one hand and detraction on the other have too often refused to him, and let us view his character soberly and without prejudice. We shall then admit that no naturalist has ever been his superior; and that he richly merited that high station in science which he held for so many years. His verbal accuracy, upon which his fame greatly depends, together with the remarkable terseness of his technical language, reduced the crude matter that was stored up in the folios of his predecessors into a form that was accessible to all men. He separated with singular skill the important from the unimportant in their descriptions. He arrayed their endless synonyms with a patience and lucid order that were quite inimitable. By requiring all species to be capable of a rigorous definition not exceeding twelve words, he purified botany of the endless varieties of the gardeners and herbalists; by applying the same strict principles to genera, and reducing every character to its differential terms, he got rid of all the cumbrous descriptions of the old writers. Finally, by the invention of an artificial system, every division of which was defined in the most rigorous manner, he was able so to classify all the materials thus purified and simplified that it seemed as if every one could become a botanist without more previous study than would be required to learn how to discover words in a dictionary. Add to all this the liveliness of his imagination, the skill with which he applied his botanical knowledge to practical objects, and the ingenuity he showed in turning to the purposes of his classification the newly-discovered sexes of plants, and we shall at once comprehend what it was that exalted Linnæus so far above his contemporaries. But great as the impulse undoubtedly was which Linnæus gave to botany, there were vices in his principles which although overlooked during his life have subsequently been productive of infinite evil. There is no such thing as a rigorous definition in natural history; this fact Ray had demonstrated to arise out of the very nature of things; and consequently the short phrases by which species and genera were characterised by Linnæus were found equally applicable to many other plants besides those for which they were intended: hence arose a new source of confusion, inferior only to that which it was intended to correct. Differential characters, which would be invaluable if we had all nature before us, were found in practice to lead to incessant errors, so soon as some new species was introduced into the calculation: they also laboured under the great fault of conveying no idea whatever of the general nature of the plants to which they related: thus the Portuguese botanist Loureiro, who attempted to determine the plants of China by the systematic writings of Linnæus, fell into the singular error that the hydrangea was a primrose. With regard to his artificial system of classification, it was found that it looked better in the closet than in the field; that the neatness and accuracy of the distinctions upon which it was divided into groups existed only upon paper, and that exceptions without end encumbered it at every turn. This, which is perhaps inseparable from all systematic arrangements, would not have been felt as so great an evil if there had been any secondary characters by which the primary ones could be checked, or if the system had really led with all its difficulties to a knowledge of things. But it was impossible not to perceive that it led in reality to little more than a knowledge of names, and that it could be looked upon as nothing beyond an index of genera and species.

The maxims however of Ray, and the great general views of that illustrious naturalist, were destined not to fade even before the meteoric brilliancy that surrounded the throne of Linnæus. A French botanist, Antoine Laurent de Jussieu, soon entered the field to oppose the latter. In the year 1789, just eleven years after the death of Linnæus, he produced under the name of 'Genera Plantarum' an arrangement of plants according to their natural relations, in which the principles of the great English botanist are tacitly admitted, and his fundamental divisions adopted, in combination, in part with those of Tournefort, in part with those which had been proposed by Adanson in his remarkable work on the 'Familles des Plantes,' and the rest with what are peculiar to the author himself. Jussieu possessed in a happier degree than any man that has succeeded him the art of adapting the simplicity and accuracy of the language of Linnæus to the exigencies of science, without encumbering himself with its pedantry. He knew the impossibility of employing any single characters to distinguish objects so variable in their nature as plants; and he clearly saw to what evils all artificial systems must of necessity give rise. Without pretending then to the conciseness of Linnæus in forming his generic characters, he rendered them as brief as was consistent with clearness; without peremptorily excluding all distinctions not derived from the fructification, he nevertheless made the latter the essential consideration; instead of defining his classes and orders by a few artificial marks, he formed them from a view of all the most essential parts of structure; and thus he collected under the same divisions all those plants which are most nearly allied to each other. Hence, while a knowledge of one plant does not by any means lead to that of another in the system of Linnæus, it leads directly to the knowledge of many more in the classification of Jussieu, which has accordingly gained the name of the 'Natural System.' This at once brought the science back to a healthy state; it demonstrated the possibilty of reducing the characters of natural groups to words, contrary to the opinion of Linnæus, who found that task altogether beyond his powers; it did away with the necessity of artificial arrangements, and, giving a death-blow to verbal botany, it laid the foundation of that beautiful but still imperfect superstructure which has been erected by the labours of Brown, De Candolle, Lindley, and others. If the system of Jussieu were not a return to that of Ray, modified only and improved by modern discoveries, we should certainly have taken this period for the commencement of

The Sixth and latest *Era* in our science. But it was reserved for a man whose fame lies chiefly in the literary world to effect the last great revolution that the ideas of botanists have undergone. In 1790, one year after the appearance of Jussieu's 'Genera Plantarum,' the German poet Göthe published a pamphlet called 'The Metamorphosis of Plants.' At that time the various organs of which plants consist had been pretty well ascertained, the distinctions between the leaf, the calyx, the corolla, the stamens, and the pistil were in a great measure understood, and the botanists were not a few who fancied there was nothing more to learn about them. Nevertheless even in the time of Theophrastus a notion had existed that certain forms of leaves were mere modifications of others that appeared very different, as the angular leaves in croton of the round cotyledons or seminal leaves of that plant. Linnæus himself had entertained the opinion that all the parts of a flower are mere modifications of leaves whose period of development is anticipated ('Prolepsis Plantarum'); Ludwig in 1757, and more especially Wolff in 1768, had stated in express terms that all the organs of plants are reducible to the axis and its appendages, of the latter of which the leaf is to be taken as the universal type. But the theory of Linnæus was fanciful; Ludwig was a writer of too little authority in his day to succeed in establishing a doctrine so much at variance with received opinions; and the theory of Wolff was propounded in a paper upon the formation of the intestines in animals, which seems altogether to have escaped the observation of botanists. Entirely unacquainted with the writings of the two latter naturalists, but aware of the 'Prolepsis Plantarum' of Linnæus, Göthe took up this important theory, and demonstrated that all those organs to which so many different names were applied, and which in fact have so many dissimilar functions to perform, were all modifications of one common type—the leaf; that the bract is a contracted leaf, the calyx a combination of several, the corolla a union of several more in a coloured state, the stamens contracted and coloured leaves with their parenchyma in a state of disintegration, and the pistil another arrangement of leaves rolled up and combined according to certain invariable laws.

Although at first Göthe's views were disregarded, they were gradually adopted, and formed the basis of inquiries in that department of botany called the Morphology of Plants. To no one is the science of Botany more indebted, from his early adoption of the generalisation of Göthe, than Robert Brown. In his 'Prodromus of the Flora of New Holland,' and in a multitude of papers in the 'Philosophical' and 'Linnæan Transactions,' he proved not only the truth of Göthe's law but practically demonstrated its importance. It was never with him a theory, as it was with its discoverer, but a great generalisation which every new fact in the vegetable kingdom served to confirm. Nor did he apply it to the superficial facts of the structure of plants, but working with the microscope he applied it to the development of the tissues of plants, and in every department of botany has made it to bear most abundant fruit. With the name of Brown in the modern history of botany we must also associate the name of another Englishman—Dr. Lindley, who, by his extensive knowledge of vegetable structures, his indefatigable industry, and power of generalisation, has contributed very largely to the perfection of the present classification of plants, as well as to the diffusion of sound general views on the subject of botany and its practical applications. To De Candolle also in recent times the progress of botany is deeply indebted, more especially for his laborious 'Prodromus of the Vegetable Kingdom,' in which not only are the orders described, but the genera and species. We can only add that in recent times the science of Botany has been indebted to the labours of the following amongst other observers :—Schleiden, Richard, Brogniart, Tulasne, Unger, Endlicher, Schacht, Von Mohl, Bischoff, Treviranus, Lehmann, Suminski, Hoffmeister, Sir W. J. Hooker, J. D. Hooker, Henfrey, Bentham, Walker Arnott, Wright, Wallich, Royle, Balfour, Babington, Leighton, Miers, J. J. Bennett, T. Thomson, Asa Gray, Henslow, Berkeley.

In order to facilitate the study of Botany by the aid of this work, we give the following Glossary of the terms employed when describing the parts of plants.

A GLOSSARY OF THE TECHNICAL TERMS MOST COMMONLY EMPLOYED IN BOTANY.

Abnormal, contrary to general rules.

Accumbent, lying against anything, in distinction to lying upon; as the cotyledons of some cruciferous plants.

Acerose, stiff and slender and sharp-pointed, as the leaves of a pine-tree.

Achenium, a small, hard, one-seeded fruit, resembling a seed.

Aciculate, needle-shaped.

Acinaciform, scymitar-shaped.

Acinus, a bunch of succulent berries; as of grapes.

Acrogen, a plant which grows at its end only, without increasing in diameter; as ferns, and all flowerless plants.

Aculeate, covered with prickles.

Aculeus, a prickle.

Acuminate, tapering to the point, but flat.

Adnate, growing to anything by the whole length.

Adventitious, appearing accidentally.

Æstivation, the arrangement of the parts of the flower before they expand.

Alabastrus, a flower-bud.

Albumen, a substance interposed in some seeds between the embryo and the seed coats.

Alburnum, the young wood; sap-wood.

Amentum, a catkin; the male inflorescence of the hazel, &c.

Amplexicaul, clasping a stem.

Anastomosing, the growing together of two parts which meet from different directions.

Androus, a Greek termination expressive of the male sex.

Anfractuous, doubled abruptly in several different directions.

Angiocarpous, having seeds inclosed in a pericarp.

Annotinous, a year old.

Anther, the case containing pollen.

Apetalous, having no petals.

Apiculate, abruptly pointed.

Apocarpous, where the carpels are distinct from each other.

Apophysis, the enlarged base of the theca of some mosses.

Apothecium, the shield, or mass of reproductive matter of a lichen.

Appendiculate, having some kind of appendages.

Arachnoid, resembling a spider's web.

Areolate, divided into little spaces.

Aril, a peculiar wrapper of some seeds; as the mace of the nutmeg.

Arista, the beard or awn of grasses.

Asci, the cases in which the spores of lichens are inclosed.

Ascidium, a hollow leaf looking like a water vessel; as the pitcher of Nepenthes.

Attenuated, gradually tapering to a point without becoming flat.

Auriculate, having two lobes (like ears) at the base.

Awn. See *Arista*.

Axil, the acute angle formed by the junction of the leaf, &c., to its axis.

Axillary, growing in an axil.

Axis, the root and stem either taken together or separately.

Baccate, fruit covered with soft flesh.

Barbate, covered with long hairs resembling a beard.

Beard, a tuft of long hairs.

Biconjugate, in two pairs, placed side by side.

Bidentate, having two teeth.

Bifarious, arranged in two rows.

Bifid, divided into two shallow lobes.

Bifoliate, having two leaflets.

Bifurcate, twice forked.

Bijugous, in two pairs, placed end to end.

Binate, growing in pairs.

Bipartite, divided into two deep lobes.

Bipinnate, twice pinnate.

Biserrate, twice serrate.

Brachiate, when branches stand nearly at right angles to the stem from which they proceed.

Bract, the leaf or leaflet from the axil of which a flower grows.

Bulb, a scaly, underground bud.

Bulbotuber, a short, roundish, underground stem resembling a bulb.

Caducous, falling off sooner or later.

Cæsious, of a bluish-gray colour.

Cæspitose, growing in tufts.

Calcar, a spur or horn; as in the nasturtium.

Calcarate, having a spur or horn.

Calyculate, having a whorl of bracts on the outside of a calyx, or of an involucre.

Calyptra, the hood of a moss.

Calyx, the external envelope of a flower.

Cambium, a viscid secretion formed in the spring between the bark and wood of Exogens.

Campanulate, bell-shaped.

Canaliculate, channeled.

Cancellate, a leaf which has veins without connecting parenchyma.

Capitate, growing in a head.

Capitulum, a collection of flowers in a head.

Capsule, any dry many-seeded fruit.

Carinate, having a kind of keel.

Carnose, fleshy.

Carpel, one of the parts of a compound pistil; a single leaf rolled up into one of the integers of a pistil.

Caruncülate, a seed having fungous excrescences growing near its hilum.

Caryopsis, a dry one-seeded fruit resembling a seed, but with no distinction between the seed-coat and pericarp.

Caudate, prolonged into a sort of tail.

Cauline, of or belonging to the stem.

Cernuous, drooping.

Chalaza, a spot on a seed indicating the place where the nucleus is united to the seminal integuments.

Ciliated, fringed with hairs like an eyelash.

Cinereous, ash-coloured.

Circinate, rolled inwards from the point to the base.

Circumscissile, dividing into two parts by a spontaneous transverse separation.

Cirrhous, terminating in a tendril.

Clavate, club-shaped.

Claw, the stalk of a petal.

Clypeate, resembling a round buckler.

Cychleate, resembling the bowl of a spoon.

Collum, the point where the stem and root are combined.

Columella, a central part of the fruit of a moss, round which the spores are deposited.

Column, the combination of stamens and style in Orchideous and other plants.

Comose, having hairs at one or both ends, if speaking of seeds; being terminated by coloured empty bracts, if applied to inflorescences.

Conduplicate, doubled together.

Confluent, growing together so that the line of junction is lost to the sight.

Conjugate, growing in pairs.

Connate, growing together so that the line of junction remains perceptible.

Connective, the fleshy part that combines the two lobes of an anther.

Connivent, converging, as the anther of a potato blossom.

Conoidal, approaching a conical form.

Continuous, proceeding from something else without apparent interruption.

Contorted, twisted in such a way that all the parts have a similar direction, as the segments of the flower of an Oleander.

Convolute, rolled together.

Corculum, the rudimentary axis which connects the cotyledons of the embryo.

Cordate, heart-shaped.

Coriaceous, of a leathery texture.

Cormus, a solid, roundish, underground stem; as in Crocus.

Corneous, of a horny texture.

Corniculate, shaped like a slender horn.

Corolla, the second of the two envelopes that surround the stamens and pistil.

Corona, a combination of fertile and barren stamens into a disk; as in Stapelia.

Corymbose, when the branches surrounding a common axis are shortest at the top and longest at the bottom, so as to form a level-topped whole.

Costa, the midrib of a leaf.

Cotyledons, the leaves of the embryo.

Crateriform, shaped like a goblet.

Crenelled or ***Crenated***, having rounded notches at the edges.

Crested, having some unusual and striking appendage arising from the middle.

Cruciate, when four parts are so arranged as to resemble the arms of a Maltese cross.

Cucullate, hooded, rolled inwards so as to conceal anything lying within.

Culm, the straw of grasses.

Cuneate, wedge-shaped.

Cupule, the cup of the acorn, the husk of the filbert, chestnut, &c.; a peculiar combination of bracts.

Cuspidate, abruptly rounded off with a projecting point in the middle.

Cuticle, the external skin.

Cyathiform, cup-shaped, more contracted at the orifice than crateriform.

Cymbiform, having the form of a boat.

Cyme, an inflorescence having a corymbose form, but consisting of repeatedly-branched divisions.

Cymose, resembling a cyme in appearance.

Decandrous, having 10 stamens.

Deciduous, falling off.

Declinate, curved downwards.

Decumbent, lying prostrate, but rising again.

Decurrent, produced downwards, as the base of a leaf down the stem.

Decussate, crossing at right angles.

Dehiscence, the act of opening of anther or fruit.

Deltoid, having the form of a triangle or Greek Δ.

Dendroidal, resembling a small tree.

Dentate, with sharp-pointed notches and intermediate curves instead of re-entering angles.

Depauperated, imperfectly developed; looking as if ill-formed from want of sufficient nutriment.

Depressed, flattened from point to base.

Diadelphous, having the stamens in two parcels.

Diandrous, having two stamens.

Dichotomous, repeatedly divided into two branches.

Dicotyledonous, having two cotyledons.

Didynamous, having two pairs of stamens of unequal length.

Didymous, growing in pairs, or twins; only applied to solids and not to flat surfaces.

Digitate, fingered, diverging from a common centre, as the fingers from the palm.

Dimidiate, half-formed, or halved, or split into halves.

Diœcious, having stamens on one plant and pistils on another.

Dipterous, having two wings.

Discoidal, with the central part of a flat body differently coloured or marked from the margin.

Disk, a fleshy circle interposed between the stamens and pistils.

Dissepiments, the vertical partitions of a compound fruit.

Distichous, arranged in two rows.

Divaricating, diverging at an obtuse angle.

Dodecandrous, having 12 stamens.

Dolabriform, hatchet-shaped.

Drupe, such a fruit as the peach, consisting of a stem surrounded by fleshy or fibrous matter.

Ducts, spiral vessels that will not unroll.

Dumose, having a compact bushy form.

Duramen, the heart-wood of timber.

Echinate, covered with hard sharp points.

Elaters, little spirally-twisted hygrometrical threads that disperse the spores of Jungermannias.

Elementary organs, the minute parts of which the texture of plants is composed.

Emarginate, having a notch at the point.

Embryo, the rudimentary plant before germination commences.

Endocarp, the hard lining of some pericarps.

Endogen, a plant which increases in diameter by addition to its centre; as a palm-tree.

Enneandrous, having 0 stamens.

Ensiform, having the form of a straight and narrow sword-blade.

Epicarp, the external layer of the pericarp.

Epidermis, the skin of a plant, in the language of some writers; the cortical integument according to others.

Epigynous, growing upon the top of the ovary, or seeming to do so.

Equitant, when leaves are so arranged that the base of each is inclosed within the opposite base of that which is next below it; as in Iris.

Estivation. See *Æstivation*.

Exogen, a plant which increases in diameter by the addition of new wood to the outside of the old wood; as an oak-tree.

Farinaceous, mealy.

Fasciated, banded.

Fasiculated, collected in clusters.

Fastigiate, when the branches of any plant are pressed close to the main stem; as in the Lombardy poplar.

Filament, the stalk of the anther.

Filiform, slender and round like a thread.

Fistular, tubular but closed at each end; as the leaf of an onion.

Flabelliform, fan-shaped.

Flagelliform, resembling the thong of a whip.

Flexuose, wavy.

Floccose, covered with little irregular patches of woolliness.

Floret, a little flower.

Floscule, ditto.

Foliaceous, having the colour and texture of a common green leaf.

Foliation, the arrangement of young leaves within the leaf-bud.

Follicle, a simple fruit opening by its ventral suture only.

Foramen, the passage through the integuments of an ovule by which impregnating matter is introduced into the nucleus.

Fovilla, the fertilising principle of pollen.

Frond, the leaf of a fern or of a palm.

Fruit, the full-grown ripened pistil.

Fugacious, lasting but a short time.

Fungoid, resembling a fungus; that is, irregular in form and fleshy in texture.

Funiculus, the stalk by which some seeds are attached to the placenta.

Fusiform, spindle-shaped, thickest in the middle, and tapering to each end.

Galbulus, a small cone whose scales are all consolidated into a fleshy ball; as in Juniper.

Galea, the upper lip of a labiate flower.

Geniculate, knee-jointed, when a stem bends suddenly in its middle.

Gibbous, prominent, projecting.

Glabrous, having no hairs.

Gladiate, the same as ensiform, but broader and shorter.

Gland, 1, the fruit of the oak, the hazel, &c.; 2, an elevation of the cuticle which usually secretes either acrid or resinous matter.

Glandular, covered with glands of the second kind.

Glaucous, covered with bloom like a plum.

Glochidate, covered with hairs which are rigid and hooked at their point.

Glume, one of the bracts of grasses.

Gymnospermous, having seeds which ripen without being inclosed in a pericarp.

Gynobase, an elevated part of the growing point of a flower-bud, rising between the carpels and throwing them into an oblique position.

Gyrate, same as *Circinate*. Also, surrounded by an elastic ring; as the theca of ferns.

Hastate, having the form of a halbert-head; that is, with a lance-shaped centre crossed at the base by two lobes of a similar form standing at right angles with the centre.

Helmet, the hooded upper lip of some flowers.

Heptandrous, having 7 stamens.

Hexandrous, having 6 stamens.

Hilum, the scar left upon a seed when it is separated from the placenta.

Hirsute, covered with harsh long hairs.

Hymenium, the gills of a mushroom; that part in Fungi where the spores are placed.

Hypocrateriform,salver-shaped; having a cylindrical tube and a flat border spreading away from it.

Hypogynous, arising from immediately below the pistil.

Icosandrous, having 20 or more perigynous stamens.

Imbricated, overlapping, as tiles overlie each other on the roof of a house.

Incumbent, lying upon anything.

Indehiscent, not opening when ripe.

Induplicate, doubled inwards.

Indusium, the membrane that overlies the sori of ferns.

Inferior, is said of a calyx when it does not adhere to the ovary; is said of an ovary when it does adhere to the calyx.

Inflorescence, the collection of flowers upon a plant.

Infundibuliform, shaped like a funnel.

Innate, growing upon anything by one end.

Innovations, the young shoots of mosses.

Intercellular, that which lies between the cells or elementary bladders of plants.

Internode, the space between two nodes.

Interrupted, when variations in continuity, size, or development alternately occur in parts which are sometimes uniform; as when pinnated leaves have the alternate leaflets much the smallest, and when dense spikes are here and there broken by the extension of internodes.

Involucre, a collection of bracts placed in a whorl on the outside a calyx or flower-head.

Involute, rolled inwards.

Labellum, one segment of a corolla, which is lower than the others, and often pendulous.

Labiate, divided into an upper and a lower lip; as the corolla of dead nettle.

Lacunose, having numerous large deep depressions or excavations on its surface.

Lamina, the blade of a leaf.

Lanceolate, shaped like a lance-head; that is, oval, tapering to both extremities.

Lateral, originating from the side of anything.

Latex, the vital fluid of vegetation.

Lax, not compact or dense.

Leaflet, a division of a compound leaf.

Legume, a kind of fruit like the pod of a pea.

Lenticular, small, depressed, and doubly convex.

Lepidote, covered with a sort of scurfiness.

Leprous, the same.

Liber, the newly-formed inner bark of Exogens.

Ligula, a membranous expansion from the top of the petiole in grasses.

Limb, the blade or expanded part of a petal.

Linear, very narrow, with the two sides nearly parallel.

Lip, same as *Labellum*.

Loculicidal, when the carpels of a compound fruit dehisce in such a way that the cells are broken through at their back.

Locusta, the spikelet, or collection of florets of a grass.

Lomentum, a legume which is interrupted between the seeds, so as to separate into numerous transverse portions.

Lunate, formed like a crescent.

Manicate, when hairs are interwoven into a mass that can be easily separated from the surface.

Marginal, of or belonging to the edge of anything.

Medullary, of or belonging to the pith.

Micropyle, a small passage through the seed, called the foramen when speaking of the ovule. See *Foramen*.

Mitriform, conical, hollow, open at the base, and either entire there or irregularly cut.

Monadelphous, with the stamens united into one parcel.

Monandrous, with one stamen only.

Moniliform, shaped like a necklace.

Monopetalous, with several petals united into one body by their edges.

Mucronate, tipped by a hard point.

Multifid, divided into many shallow lobes.

Multipartite, divided into many deep lobes.

Muricated, covered with short, broad, sharp-pointed tubercles.

Muriform, resembling the bricks in the wall of a house.

Navicular, shaped like a very small boat.

Nectary, any organ that secretes honey.

Nerves, the stronger veins of a leaf.

Node, the part of a stem from which a normal leaf-bud arises.

Normal, according to general rules.

Nucleus, the central part of an ovule, or a seed.

Nucule, a small hard seed-like pericarp.

Oblique, larger on one side than on the other.

Ochrea, two stipules united round the stem into a kind of sheath.

Octandrous, having 8 stamens.

Operculum, the lid of the theca of a moss.

Ovary, the hollow part of a pistil containing the ovules.

Ovate, having the figure of an egg.

Ovule, a rudimentary seed.

Palate, the lower surface of the throat of a labiate corolla.

Palea, either the inner bracts of the inflorescence of a grass, or the bracts upon the receptacle of the flower-head of a Composita.

Paleaceous, covered with paleæ.

Palmate, the same as *Digitate*, only the divisions more shallow and broader.

Panduriform, oblong, narrowing towards the base, and contracted below the middle.

Panicle, a compound raceme; a loose kind of inflorescence.

Papilionaceous, a flower consisting of standard, wings, and keel, like that of a pea.

Pappus, the calyx of a Composita; as of a dandelion.

Parenchyma, the pulp that connects the veins of leaves.

Parietal, growing from the lining of anything.

Pectinate, divided into long, close, narrow teeth like a comb.

Pedate, palmate, with the lateral segments lengthened and lobed.

Pedicel, one of a great many peduncles.

Peduncle, a flower-stalk.

Peltate, attached within the margin.

Pentandrous, having 5 stamens.

Perfoliate, surrounding a stem by the base, which grows together where the margins touch.

Perianth, a collection of floral envelopes, among which the calyx cannot be distinguished from the corolla, though both are present.

Pericarp, the shell of a fruit of any kind.

Perichætium, the leaves at the base of the stalk of the fruit of a moss.

Perigone, same as *Perianth*.

Perigynous, growing from the sides of a calyx.

Perisperm, same as *Albumen*.

Peristome, a curious set of processes surrounding the orifice of the theca of a moss.

Peronate, laid thickly over with a woolly substance ending in a sort of meal.

Personate, labiate, with the palate of the lower lip pressing against the upper lip.

Petal, one of the parts of a corolla.

Petaloid, resembling a petal in colour and texture.

Petiolar, of or belonging to the petiole.

Petiole, the stalk of a leaf.

Phyllodium, a petiole transformed into a flat leaf-like body.

Pileus, the cap of a mushroom.

Pilose, covered with short fine hairs.

Pinnate, divided into a number of pairs of leaflets; *bipinnate*, each leaflet is also pinnate; *tripinnate*, each secondary leaflet pinnated also.

Pinnatifid, divided in a pinnated manner nearly down to the midrib.

Pistil, the combination of ovary, style, and stigma.

Pith, the central column of cellular tissue in an Exogen.

Placenta, the part of the ovary to which the ovules are attached.

Plane, quite flat.

Plumule, the rudiment of a stem in the embryo.

Pollen, the powder contained in an anther.

Pollen-Tubes, the membranous tubes emitted by pollen after they fall on the stigma.

Polyadelphous, when the stamens are combined into more than two parcels.

Polyandrous, when there are more than 20 hypogynous stamens.

Polypetalous, when the petals are all distinct.

Pome, a fruit like that of the apple, pear, &c.

Præfloration, same as *Æstivation*.

Prickle, same as *Aculeus*.

Primine, the external integument of the ovule.

Pseudobulb, the solid above-ground tuber of some Orchideæ.

Pubescent, covered with very fine soft down.

Pulverulent, covered with a powdery appearance.

Putamen, same as *Endocarp*.

Pyriform, shaped like a pear.

Quartine, the innermost integument but one of the ovule.

Quinate, combined in fives.

Quintine, the innermost integument of the ovule.

Raceme, an inflorescence like that of the currant.

Rachis, the axis of inflorescence.

Radical, arising from the root.

Radicle, the rudimentary root in the embryo.

Ramenta, soft, ragged, chaff-like hairs growing upon the petiole of ferns.

Raphe, the line of communication between the hilum and chalaza.

Raphides, acicular or other crystals scattered among vegetable tissue.
Reniform, kidney-shaped.
Resupinate, inverted, so that the part which is naturally lowermost becomes uppermost.
Reticulated, traversed by veins having the appearance of network.
Retuse, blunt, and turned inwards more than obtuse.
Rhizoma, a creeping stem like that of Iris.
Ringent, same as *Personate*.
Root-Stock, same as *Rhizoma*.
Rostrate, furnished with a sort of beak.
Rosulate, having the leaves arranged in little rose-like clusters.
Ruminated, pierced by numerous perforations full of chaffy matter like a nutmeg.
Runner, the prostrate stem of such plants as the strawberry.

Sagittate, resembling the head of an ancient arrow.
Samara, a kind of one-seeded indehiscent pericarp, with a wing at one end.
Sap-Wood, the newly formed wood, which has not been hardened by the deposit of secreted matter.
Sarcocarp, the intermediate fleshy layer between the epicarp and endocarp.
Scale, an abortive leaf.
Scape, the flowering stem of a plant.
Scarious, dry, thin, and shrivelled.
Scrobiculate, irregularly pitted.
Scutellum, the fructifying space upon the thallus of a lichen.
Secund, arranged or turned to one side.
Secundine, the second integument of the ovule.
Sepals, the leaves of the calyx.
Septa, same as *Dissepiment*.
Septicidal, when the dissepiments of a fruit are divided into two plates at the period of dehiscence.
Septifragal, when the dissepiments of a fruit are broken through their middle by the separation of the back of the carpels from the centre.
Sericeous, silky.
Serrate, toothed like the edge of a saw.
Sessile, seated close upon anything, without a stalk.
Setose, covered with setæ or bristles.
Shield, the fructification of lichens.
Sigmoid, bent like the letter S.
Silicle, a short two-valved pod, such as is found in garden cress.
Silique, the same but longer; as in the cabbage.
Sinuate, turning in and out in an irregular manner.
Sori, the fructification of ferns.
Spadiceous, resembling a spadix, or bearing that kind of inflorescence.
Spadix, the inflorescence of an arum; an axis closely covered with sessile flowers, and inclosed in a spathe.
Spathaceous, inclosed within a spathe, or bearing that kind of bract.
Spathe, a large coloured bract which incloses a spadix.
Spatulate, shaped like a druggist's spatula; that is, long, narrow, and broadest at the point.
Spike, an inflorescence in which the flowers are sessile upon their axis.
Spikelet, one of a great many small spikes collected in a mass; as in grasses.
Spine, a stiff, sharp-pointed, leafless branch.
Spongiole, or *Spongelet*, the tender growing tip of the root.
Spore, or *Sporule*, the reproductive body of flowerless plants, analogous to the seed of flowering plants.
Squarrose, composed of parts which diverge at right angles, and are irregular in size and direction.
Stamen, the fertilising organ of a flower, consisting of filament and anther.
Standard, the upper single petal of a papilionaceous flower.
Stellate, arranged in the form of a star.
Stigma, the upper end of the style, on which the pollen falls.
Stipe, the stalk that bears the head of a mushroom; also the stalk of the leaf of a fern; also the stalk of anything except of a leaf or a flower.
Stipulate, furnished with stipules; *exstipulate*, having no stipules.
Stipule, the scale at the base of some leaf-stalks.
Stomate, a minute hole in a leaf, through which respiration is supposed to be carried on; a breathing pore.
Strigose, covered with stiff unequal hairs.
Strophiolate, having little fungous excrescences surrounding the hilum.
Stupose, having a tuft of hairs in the middle or at the end.
Style, the stalk of the stigma.
Subulate, awl-shaped.
Syncarpous, having the carpels consolidated.

Terete, taper.
Ternate, united in threes.
Testa, the skin of the seed.
Tetradynamous, having 6 stamens in four parcels; two of which consist of two stamens, and two of one each.
Tetrandrous, having 4 stamens.
Thallus, the leafy part of a lichen; the union of stem and leaf in those and some other tribes of imperfect plants.
Theca, the case which contains the sporules of flowerless plants.
Tomentose, covered with short close down.
Toothed, the same as *Dentate*.
Torulose, alternately contracted and distended.
Torus, the growing point of a flower on which the carpels are placed.
Triandrous, having 3 stamens.
Trifarious, arranged in three rows.
Trifid, divided into three lobes.
Trifoliolate, having three leaflets.
Tripartite, divided into three deep divisions.
Tripinnate, when each leaflet of a pinnated leaf is pinnate; and the leaflets of the latter are pinnate also.
Triternate, when each leaflet of a ternate leaf is ternate; and the leaflets of the latter are ternate also.
Truncate, abruptly cut off.
Tube, the part of a flower where the bases of the sepals, petals, or stamens are united.
Tuber, a deformed, fleshy kind of underground stem.
Turbinate, shaped like a spinning top.

Umbel, an inflorescence whose branches all radiate from one common point.
Umbilicate, having a depression in the middle.
Umbonate, having a boss or elevated point in the middle.
Undulated, wavy.
Unguiculate, furnished with a claw, or short stalk.
Urceolate, shaped like a pitcher.
Utricle, a small bladder.

Vagina, the sheath formed by the convolution of a flat petiole round a stem.
Valve, one of the parts into which any dehiscent body divides.
Vascular, containing vessels; that is, spiral vessels or ducts.
Ventricose, inflated.
Vernation, the manner in which the young leaves are arranged in their leaf-bud.
Verrucose, covered with warts.
Versatile, swinging lightly upon a sort of pivot.
Verticillate, arranged in a whorl.
Vexillum, same as *Standard*.
Villous, covered with long soft shaggy hair.
Virgate, having long slender rod-like shoots.
Vitellus, a fleshy bag, interposed between the embryo and albumen in some seeds.
Vittate, striped, as distinguished from fasciate, or banded.
Whorl, an arrangement of more leaves than two around a common centre upon the same plane.

BOTAURUS. [BITTERN.]

BOTHRIOCEPHALUS. [ENTOZOA.]

BOTHYNO'DERES, a genus of Coleopterous Insects of the family *Curculionidæ*. It is known by the following characters:—Body oblong; rostrum thick, longer than the head, bent downwards, and having a longitudinal elevated line above. Antennæ geniculated, rather short and thick, twelve-jointed; the basal joint long, thickened towards the apex; the second joint short and stout; the third twice as long as the last; the four following short; the eighth rather broader than the last; the remaining or terminal joints form a spindle-shaped club. Thorax narrower before than behind, the base with an impression in the middle. Elytra oblong, with an obtuse tubercle towards the apex. Legs moderate; femora simple.

This genus apparently links the genera *Cleonus* and *Lixus* together. The species are in general very prettily mottled, the common colours being black, or gray, and white. In this country but one species has yet been discovered, and of that only two or three specimens have been found: it is about half an inch long and of a white colour, having the central part of the thorax, together with a fascia and four spots on the wing-cases, black. The species here described is the *Bothynoderes albidus* (*Curculio albidus* of Fabricus).

BOTIA, a genus proposed by Dr. J. E. Gray for the Spined Loche, or Groundling, usually included under *Cobitis*. [COBITIS.]

BOTRY'CHIUM, a genus of Ferns belonging to the sub-order *Osmundaceæ* and the tribe *Ophioglosseæ* of that family. It has distinct thecæ disposed in a compound spike attached to a pinnate or bipinnate frond. There is only one species a native of Great Britain, the *B. Lunaria*, Common Moonwort. It has a solitary pinnate frond, with notched or crenate, lunate or fan-shaped pinnæ. This is not a very conspicuous fern, but has been observed in almost every part of Great Britain. It grows on dry open heaths, elevated pastures, and waste lands which are generally shunned by other species of ferns.

In former times the ferns had a great reputation in medicine, not so much on account of their obvious as their supposed virtues. The lunate-shape of the pinnæ of this fern gave it its common name, and was the origin of much of the superstitious veneration with which it was regarded. When used it was gathered by the light of the moon. Gerarde says:—"It is singular to heal green and fresh wounds. It hath been used among the alchymists and witches to do wonders withall, who say that it will loose locks and make them to fall from the feet of horses that grase where it doth grow, and hath been called of them Martagon, whereas in truth they are all but drowsy dreams and illusions; but it is singular for wounds as aforesaid." Its healing powers are now however as much disregarded as its magical ones.

B. Virginicum, the Rattlesnake Fern, is a native of North America, and is the largest of the species. It is called Rattlesnake Fern from the fact of its growing in places where this venomous reptile is usually found. The other species of *Botrychium* are mostly natives of North America. (Loudon, *Encyclopædia of Plants;* Newman, *History of British Ferns*).

BOTRYLLIDÆ, a tribe of Tunicated *Mollusca*, of which the genus *Botryllus* is the type. The species are not uncommon on the coasts of Britain. They form translucent jelly-like masses of various hues, sometimes uniform in tint and sometimes beautifully variegated, and are found encrusting the surface of rocks or attached to the fronds of some of the large sea-weeds that grow at the bottom of the sea, or not unfrequently attached to the other forms of *Mollusca*. On examining one of these gelatinous masses closely they present the appearance of stars, having a central point and numerous radii. Unless examined closely they present little signs of life, but when a magnifying power is applied currents of water are seen passing to and from small apertures with which the surface is covered. Savigny, the illustrious French naturalist, was the first observer who apprehended the nature of these curious beings, and gave an account of their structure in his celebrated 'Mémoires sur les Animaux sans Vertèbres.' Before his time the *Botryllidæ* had been confounded with the *Polypes*, and regarded as analogous to *Alcyonium*. The earliest figures of them are to be found in the 'Philosophical Transactions' for 1757 by Schlosser, who was a correspondent and friend of John Ellis. The latest researches upon these creatures are those of Milne-Edwards in 1839, who in a paper read before the Institute of France fully confirmed the correctness of Savigny's views. The animals of this tribe have been divided into several genera, of which the following are British:—

Aplidium, Sav. Gelatinous or cartilaginous, with no central cavity, but a distinct circumscription. Animals 3 to 25 in number, in a single row, at equal distances from the centre of their common axis. Three species are given by Forbes and Hanley in the 'British Mollusca,' but with the statement that they require "careful re-examination." These are *A. Ficus*, Linn.; *A. fallax*, Johnston; *A. nutans*, Johnston.

Sidnyum, Sav. The mass presents the appearance of a number of heads of Madrepore or Cladocora, each formed of a simple cone truncated and starred at the summit, rising from a common encrusting base, the whole being grouped closely together. There is but one species, *S. turbinatum*, which occurs abundantly on the north coast of the Isle of Man and other parts of the British Islands.

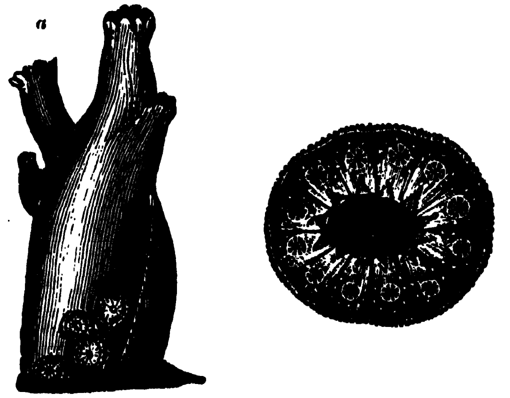
Polyclinum, Sav. Mass sessile, gelatinous, or cartilaginous; polymorphous, composed of more or less multiplied systems, convex, radiated, each having a central cavity, and being more or less distinctly circumscribed. Individuals 10 to 150 placed at unequal distances form a common centre. *P. aurantium*, Milne-Edwards, has been found at Cullercoats.

Amouroucium, Milne-Edwards. Mass lobed or encrusting, sessile or pedunculated, fleshy or cartilaginous, composed of many systems, each having a central cavity. *A. proliferum*, M. Edwards, has been found in Belfast Bay. *A. Nordmanni*, M. Edwards, and *A. Argus*, M. Edwards, have been taken at Falmouth by Mr. Alder.

Leptoclinum, Milne-Edwards. Mass thin, sessile, encrusting, polymorphous, coriaceous or gelatinous, composed of many systems; vents opening into a common cloaca. The following species have been taken on various parts of the British coasts:—*L. maculosum*, *L. asperum*, *L. aureum*, *L. gelatinosum*, *L. Listarianum*, *L. punctatum*.

Distoma, Gaertner. Mass sessile, semicartilaginous, polymorphous, composed of many systems, usually circular. Anal and branchial orifices regularly and equally 6-rayed. Two species, *D. rubrum* and *D. variolosum*, are British.

Botryllus, Gaertner. The animals are grouped in single stars, and lie horizontally with the vent far from the branchial orifice. The branchial orifices simple and arranged around a common cloaca. *B. Schlosseri*, Pallas. This is the species figured by Schlosser in the 'Philosophical Transactions.' It is one of the most beautiful, as it is one of the most common species of the family. Living specimens of this and the other species of *Botryllidæ* are now in the Aquavivarium of the Zoological Society in the Regent's Park Gardens. The other British species are *B. polycyclus*, Savigny; *B. gemmeus*, Sav.; *B. violaceus*, Milne-Edwards; *B. Smaragdus*, M. Edwards; *B. bivittatus*, M. Edwards.



a, A group of *Botryllus Schlosseri* upon *Ascidia intestinalis*; *b*, a disk magnified.

Botrylloides, Milne-Edwards. The stars formed by the systems of these animals are irregular and ramifying. The bodies are placed vertically and the two orifices approximate. The following species are British:—*B. Leachii*, Sav.; *B. albicans*, M. Edwards; *B. rotifera*, M. Edwards; *B. rubrum*, M. Edwards.

(Forbes and Hanley, *History of British Mollusca.*)

BOTRYOGENE, native red Sulphate of Iron. It occurs crystallised, the crystals being usually aggregated in globular reniform and botryoidal masses. The primary form is that of an oblique rhombic prism. The colour is deep hyacinth-red and ochre-yellow with a yellow streak. The hardness is from 2·25 to 2·5. The lustre vitreous; translucent. The taste slightly astringent. The specific gravity 2·039. It is composed of—

Sulphuric Acid	32·55
Peroxide of Iron	23·86
Protoxide of Iron	10·71
Water	32·85

It is found in the great copper-mine of Fahlun in Sweden.

BOTRY'TIS, one of the obscure parasitical genera of *Fungi*, to which what is called Mildew is often attributable. The plants consist of little cells adhering end to end; of these a part lies prostrate on the surface of the plant that bears them, the other rises erect from the surface and bears a collection of roundish seed-cases at the extremity. From the spores contained in these cases the plants are propagated, and seeing that their size is so microscopic in all cases as to escape our vision unaided by glasses, and that what seems to the naked eye a thin brownish white patch upon a leaf is in reality a dense forest of such plants, their power of dissemination must be very great. They attack the fibres of vegetable fabrics, such as linen and cotton when placed in damp places, and the decayed stems of various plants, decaying apples, pears, grapes, &c. They are always superficial, and never intestinal.

BOTS are the Larvæ or Caterpillars of the Gad-Fly, belonging to the order *Diptera* and the genus *Œstrus*, and distinguished by this peculiarity, that they pass the larval state of their existence within some living animal, and feed on the juices or substance of that animal. There are numerous species of them. Every quadruped on which they prey has its peculiar fly. The notice of a few of those most commonly known will suffice.

The *Œstrus Equi*, or Gad-Fly of the Horse, belongs to the genus *Gasterophilus* of some entomologists, so called from its larvæ inhabiting the stomach of that animal. It is distinguished from the other *Œstri* by the smoothness of the thorax, and by the eyes in both sexes being equidistant from each other, not quite half an inch in length, with gauze-like yellow and brown wings, its chest of a rusty colour approaching to a brown hue on the sides and with a yellow tinge posteriorly, its belly of a reddish-brown superiorly and a dirty gray beneath, with its extremity almost black. The whole insect is thickly covered with down. The Gad-Fly is seen in the latter part of the summer very busy about horses: this is the impregnated female depositing her eggs. She approaches the horse, selects some part which he can reach with his tongue, and which he is in the frequent habit of licking; she balances herself for a moment, and then suddenly darting down, deposits an egg on one of the hairs, which adheres by a glutinous substance that surrounds it. She continues her labour with wonderful perseverance until she has parted with fifty or a hundred eggs, and then having exhausted herself, she slowly flies away, or drops at once and dies.

If a horse at grass is carefully examined in August, some hundreds of these minute eggs will be found about its legs and the back part of the shoulder, and few or none out of the reach of his tongue. In two or three days these eggs are sufficiently matured to be hatched. Possibly the horse feels a little inconvenience from all this glutinous matter sticking about and stiffening the hair, and he licks the part, and by the pressure of the tongue, and the mingled influence of the warmth and moisture of it, the ova are burst, and a small worm escapes from each. It clings to the tongue, and is thus conveyed into the mouth; thence it is either carried with the food into the stomach, or, impelled by instinct, it travels down the gullet, being too small to inconvenience or annoy the horse. Thus it reaches the stomach, and by means of a hook on each side of its mouth affixes itself to the cuticular or insensible coat of that viscus. It scoops out a little hole, into which its muzzle is plunged, and there it remains until the early part of the summer of the following year, feeding on the mucous or other matter which the coats of the stomach afford. It has now become an inch in length and of corresponding bulk, and ready to undergo its change of form. It detaches itself from the cuticular coat to which it had adhered, and plunges into the food which the other and digestive portion of the stomach contains; it passes with the food through the whole length of the intestines, and is discharged with the dung. Sometimes it is not perfectly enveloped in the fecal mass; it then clings to the sides of the anus, and hangs there firmly until there is a soft place beneath on which it may drop; it then hastens to burrow into the earth, and, if it has escaped the birds that are eagerly watching for it, it has no sooner hollowed for itself a convenient habitation than a shelly covering is formed around it, and it appears in the state of a pupa or chrysalis.

It here lies torpid for a few weeks, preparing to undergo its last change. It assumes the form of a perfect fly; it then bursts from its prison, rises in the air, and seeks its mate. The work of fecundation being accomplished, the male immediately dies: the female lingers a day or two in order to find the proper deposit for her eggs, and her short life also terminates.

It is in the larva or caterpillar state that the Bot is most known. The stomach of the horse sometimes contains an almost incredible number of them, the cuticular portion of that organ being in a manner covered with them. In a few instances they have been decidedly injurious. Having mistaken the upper part of the windpipe for their residence, and fastening themselves on the edges of the opening into it, have produced a cough which no medicine could alleviate, and which increased with the growth of the Bot, until a degree of irritation was excited under which the animal sunk. They have also travelled farther than the stomach, and have irritated and choked the first intestine, and thus destroyed the horse; and, even in their natural habitation, under probably some diseased state of the stomach arising from other causes, they have perforated it and caused death.

These however are rare occurrences; they are exceptions to a general rule. The plain matter of fact is, that a horse that has been turned out in July and August, and therefore almost necessarily has bots, enjoys just as good health as another that has been stabled during this period. He is in as good condition, and as fully capable of work when the cuticular coat is crowded with full-formed bots as he is at any other time; and his health is unaffected when they are passing through the intestines to seek a new habitation.

A smaller species of Bot, called from its colour the Red-Bot, is occasionally found in the stomach; but the fly from which it proceeds has never been accurately described. There is no ground for the assertion that the red-bot is more injurious than the common bot.

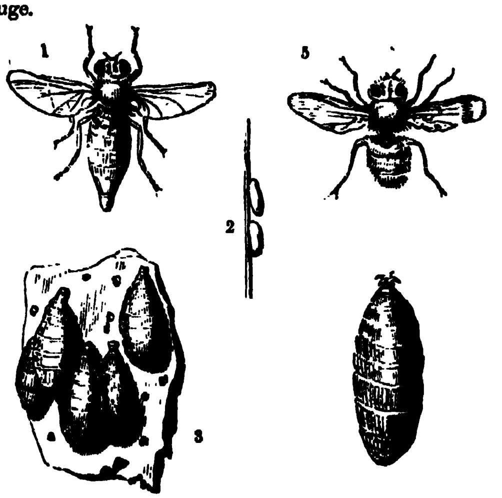
A third species, the *Œstrus hemorrhoidalis*, or Fundament-Bot, is better known. The fly is considerably smaller than the common *Œstrus Equi*. It is of a brown colour, with the extremity of the body rounded and yellow, and the mouth is furnished with exceedingly sharp pincers. This fly may be seen darting between the thighs of the horse and around its croup, and following the motions of the tail until the animal is preparing to dung. During the evacuation of the dung, and the subsequent protrusion of the intestine, it darts upon and tears the gut with its pincers, and deposits an egg in every wound. The horse does not seem to suffer any pain during this operation, for he stands passive; and the little worm, soon produced from the egg, establishes its abode in the place in which it was deposited. It likewise remains its stated time in the intestine, and escapes at the same time that the common bot does from the stomach. These bots are often seen within the verge of the anus, and occasionally seem to be productive of a slight degree of irritation. They are smaller than the common bot, and distinguished from the red-bot by their colour. An injection of linseed-oil will generally dislodge them.

The *Œstrus Ovis*, or Gad-Fly of the Sheep, is a more formidable insect. It is smaller than the *Œstrus* of the Horse: its body is of a dark-brown colour, spotted with white, the white sometimes so much prevailing as to give a grayish hue to the fly. It may often be seen in copses, and particularly on rails in the neighbourhood of a copse. Every shepherd ought to make himself acquainted with it, for it may then be easily crushed and destroyed. It prevails most in June and July, and is sometimes an intolerable nuisance in woody countries. If only one of them appears the whole flock is struck with terror; and if there is any place in the field devoid of pasture the sheep crowd to it, turning their heads towards the centre of the group, with their muzzles to the sand, and their feet in continual motion in order to secure themselves from the attack of their foe. The *Œstrus* endeavours to get at the inner margin of the nostril, and, darting upon it with the quickness of lightning, deposits her egg. The warmth and moisture of the part speedily hatch it, and the little worm escapes. It crawls up the nostril, it threads all the sinuosities of the passage, and finds its way to some of the sinuses connected with the nose. The irritation which it occasions as it travels up the nose seems to be exceedingly great. The poor animal gallops furiously about, snorting violently, and almost maddened by the annoyance. At length the worm reaches some of the convolutions of the turbinated bones of the nose, or the antrum or cavity of the upper jaw, or the frontal sinuses; it fastens itself on the membrane by the two hooks with which, like the others, it is provided, and there it remains until April or May in the succeeding year.

There are seldom more than three or four of these bots in each sheep; and when they have reached their appointed home, like the bots in the stomach of the horse, they are harmless. Some strange but groundless stories have been told of gleet from the nose, giddiness, and inflammation of the brain having been produced by them.

The larva or bot remains in the sinus until it has fully grown. It then detaches itself from the membrane, creeps out the same way by which it entered, and again sadly annoys the animal for a little while, the sheep making the most violent efforts to sneeze it out. At length the grub being dropped, burrows in the earth, becomes an oval and motionless chrysalis, and six weeks or two months afterwards it breaks from its prison a perfect fly. The work of propagation being effected the male, like that of the *Œstrus Equi*, dies; the female lingers on a little while until she has safely deposited her ova. She takes no food, for she has no organs to receive or digest it. She accomplishes her task and expires.

The *Œstrus Bovis*, or Gad-Fly of the Ox, is larger than either of the others. Its chest is dark-brown with a yellow patch on the back, and the rounded abdomen has alternate rings of a brown and orange colour. The fatty and cellular substance beneath the skin of the ox is the residence of its larvæ. The fly almost uniformly selects a young beast in good condition, and, alighting on the back a little on one side of the spine, it punctures the skin and drops one of its eggs into the perforation, and with it probably some acrid fluid which causes temporary but intense pain. The ox darts away, and runs bellowing over the field with his head protruded and his tail extended. His companions smarting from the same pain or dreading a similar attack also gallop wildly in every direction, hastening if it be in their power to some pond or stream where their enemy is afraid to follow them. A small tumour—a warble—presently appears on the back, which being carefully examined is found to contain a little white worm. This worm grows and assumes a darker colour, and becomes a perfect bot; and there it remains abundantly nourished by the fatty matter around it until the following June, when it begins to eat its way through the wall of its cell. Many a bird aware from the uneasiness of the beast of what is going forward is ready to seize the bot as it is forcing itself through the aperture which it has made, and the cattle too instinctively crowd to the water in order that the intruder may fall into the stream and thus be lost. In one of these ways the great majority of the larvæ perish, but a few reach the ground, speedily burrow into it, pass through their chrysalis state, and reappear in August in their last and perfect form. They also immediately set to work to secure the perpetuation of their species, regardless of the annoyance to the animals within whose frame they find a refuge.



1, The female of the *Œstrus Equi* nearly double its natural size; 2, the eggs, also magnified, deposited on and adhering to the hair; 3, the bots, one-half of their natural size, adhering by their tentacula, or hooked mouths, to the cuticular portion of the stomach. Some of them are supposed to be recently detached, and the excavations which they had made in the cuticular coat are seen; 4, the full-grown bot detached; 5, the *Œstrus Ovis*, or Gad-Fly of the Sheep.

The farmer does not pay the attention which he ought to these warbles. It is true that the cattle when the tumour has once formed do not appear to suffer any inconvenience from its existence, and the farmer is accustomed to associate with the appearance of a few warbles the certainty of the thriving condition of the beasts; but he forgets the pain and terror which the animal has already suffered and that which it has yet to undergo, and he also forgets the deterioration of the hide. The hole made by the bot in its escape will apparently close, but not until after a considerable period has elapsed, and never with a substance so firm and durable as the first. It is easy to destroy the creature in its cell. The pressure of the finger and thumb will effect it, and while the beast will escape considerable annoyance the hide will not be damaged.

The goat and the different species of deer, and in fact almost all animals, have their peculiar tormentors, but the distinctions and habits of these varieties of the *Œstrus* are not well known.

BOTTLE-GOURD. [LAGENARIA.]

BOTTLE-HEAD. [DELPHINUS.]

BOTTLE-TIT. [PARUS.]

BOULANGERITE, a native Sulphuret of Lead and Antimony. It occurs massive. The colour is bluish-gray. The fracture exhibits a crystalline structure. The lustre is metallic. Specific gravity 5·97. It is found at Molières in France and at Nertschinsk. The analysis of the ore from Molières by Boulanger gives the following :—

Lead	53.9
Antimony	25·5
Sulphur	18·5
Iron	1·2
Copper	0·9
	100.0

BOULDER-FORMATION, in Geology, a title which has been introduced to supplant that of Diluvial Deposits. Till is an equivalent term employed in Scotland. By various writers these accumulations are ranked in the ill-defined class of Pleistocene Deposits.

BOULDERS. Of the materials of which superficial deposits of the debris of ancient rocks are composed some are of large size, and have been called Boulders or Erratic Blocks. The portions of smaller size are called Gravel. Boulders are generally found not far from the rocks from which they have been broken, whilst gravel is carried to a great distance. Instances however are not wanting in which boulders have been transported an immense distance. They have been transported from Norway and Sweden to the plains of Germany, and from the mountains of Scotland and Cumberland to the centre and south of England. So large are some of these boulders, and the obstacles such as intervening hills, valleys, and seas so great, that the mode of their transportation can be accounted for in no other way than by supposing that they have been floated across them in masses of ice, which as they have melted have dropped them in the places where they are now found when those places were at the bottom of a sea. The largest boulders seem to have drifted in all cases from northern and southern points towards the warmer districts in the temperate and tropical parts of the earth.

BOUNCE, a name given to the large spotted Dog-Fish (*Scyllium Catulus*, Cuvier). [SCYLLIUM.]

BOURNONITE, a compound of the sulphurets of lead, antimony, and copper. It occurs massive and crystallised. The primary form is a right rhombic prism. The cleavage is parallel to the primary planes and to both the diagonals of the prism. Colour, steel or blackish-gray; streak similar. The fracture uneven, conchoidal. Hardness 2·5 to 3·0. Lustre metallic. Opaque. Specific gravity 5·79 to 5·83. It is found in Cornwall, Clausthal, Pfaffenberg, Mexico, and Peru. The following analysis of the mineral from Cornwall is by Hatchett:—

Sulphur	17·00
Lead	42·62
Antimony	24·23
Copper	12·80
Iron	1·20
	97·85

BOVIDÆ, a family of the Ungulate or Hoofed division of the *Mammalia*, is thus characterised by Dr. J. E. Gray in the 'Catalogue of the Mammalia in the British Museum':—

Two middle toes separate; cutting teeth eight below; upper jaw callous; grinders six in each jaw. Frontal bones produced, generally bearing horns, especially in the males. Gullet with two long pouches just before the stomach, used for holding and soaking the food before it is chewed. Using their head and horns in defence.

The *Bovidæ* include the following tribes:—

Bovina, Cervina, Giraffina, Moschina, Camelina.

The tribe *Bovina* is again divided into the sub-tribes:—

Boveæ, Strepsicereæ, Antilopeæ, Capreæ, Oveæ.

In this article the species of the sub-tribe *Boveæ* which includes our common Oxen will be described. The *Antilopeæ* and *Strepsicereæ* are described under ANTILOPEÆ, and the other sub-tribes under OVEÆ and CAPREÆ.

The *Boveæ* are characterised by having the horns smoothish, spread out on the sides, cylindrical or depressed at the base, situated on the frontal ridge, and bent laterally outward and recurved at the tips. The nose is broad, with the nostrils on the side. The skull has no suborbital pit or fissure; the cutting teeth are nearly equal-sized, and slightly shelving outwards. The knee (or wrist) is below the middle of the fore leg, the cannon bone being shorter than the fore-arm bone.

Dr. Gray observes that the genera of *Boveæ* may be divided into groups by the condition of the muffle. Thus *Bos, Bibos, Bison, Bubalus*, and *Anoa* have a naked moist muffle, whilst *Poephagus, Ovibos*, and *Budorcas* have a hairy ovine muzzle. The first series are characterised in their habits by living on the plains of warm or temperate regions, whilst the last are inhabitants of mountainous and snowy regions.

The genera *Bos, Bubalus, Bibos*, and *Anoa* are the true Oxen, and are distinguished from *Bison* (the Bisons) by having their bodies covered with rather stiff hair; the shoulder proportionate to the haunches, and the cannon bone of the hind and fore legs of equal length.

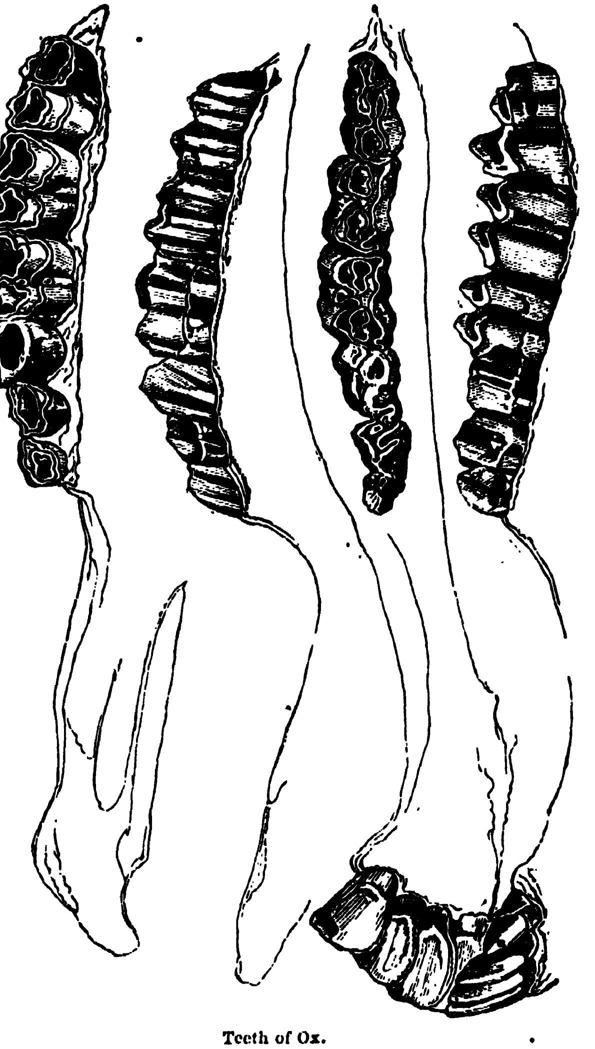
Bos. Horns cylindrical, conical, nearly circular at the base, curved upwards and outwards, far apart at the base, on the sides of the upper part of the ridge at the hinder end of the occipital plane. The facial and frontal portion of the skull equal. Dorsal ridge distinct, sometimes produced into a dorsal hump.

Bos Taurus, the Bull. The forehead is flat; the withers not humped.

This species is the common Ox, which is so widely diffused over the surface of the earth, and of whose utility to man we have very early records. Dr. Gray gives upwards of forty synonyms for this species. It is the *Bos Taurus* of Pliny; *Taurus castratus* of Johnston; *Vacca* of Gesner; *Bos domesticus* and *Bos Taurus* of Linnæus; the Bull, Ox, and Common Ox of Pennant and Shaw; the Stier and Ochs of German writers; and Bœuf of the French; it is the White Scotch Bull, the *Bisontes jubati* of Boethius; the White Urus of Colonel H. Smith; the Chillingham Bull of Gray; the Wild or White-Forest Cow and Bull of Low; the Wild Cattle of Bewick. Varieties of this species are known to the grazier by a large number of names: some of these are generally recognised, and have characteristic types, as the Pembroke Bull, the West Highland Bull, the Zetland Cow, the Kerry Cow, the Alderney Cow, the Fifeshire Cow, Long-Horned or Lancashire Bull, the English Short-Horn Cattle, the Short-Horn Ox, the Polled Suffolk Cow, the Sussex Ox, the Yorkshire Cow. Amongst those recognised of foreign rearing we may mention the Holstein or Dutch Bull, the Polish Bull, the Hungarian Bull, the South African Long-Horned Cattle, Swiss Cattle, Alpine Cattle, the Syrian Ox, Moldavian Cattle, the Itailan Campagna Bull, Spanish Bulls, Egyptian Cattle, the Laut of Africa—*Bos humilis* of Frisch, the Galla Ox—*Bos Taurus Abyssinicus* of Gmelin, the Cattle of Peauby, the Cattle of Brazil, the Cattle of Chili, the Nata or Niata of Buenos Ayres, and the Falkland Islands Wild Cattle.

As this species may be taken as the type of the tribe, we shall here present a sketch of its organisation.

We shall first speak of the skeleton. The front or forehead is wide and flattened; the lacrymal bone is enlarged below, and leaves no open space between it and the nasal bone. The upper occipital and parietal bones unite at so early a period into a single bone, that the calf almost at its birth has them already in the confluent state; but in the earlier stages of the fœtus the two parietal and the two interparietal bones are distinguishable. The occipital suture remains strong below the occipital crest, and so differs from the other ruminants; and the frontal suture reaches up to this crest, thus forming the principal character of the physiognomy of the Ox. The hole analogous to the sphæno-palatine aperture is enormous, and is hidden in the sunken space behind the orbital or supermolar prominence of the maxillary bone; at its superior border a small portion only of the vomer is perceptible. The tympanic cavities terminate in long sharp points, and between them the basilary bone presents two strong prominences. The temporal ala of the anterior sphenoid bone, which in the antelopes and stags has the crest but slightly projecting, has in the Oxen a strong and sharp projection.



Teeth of Ox.

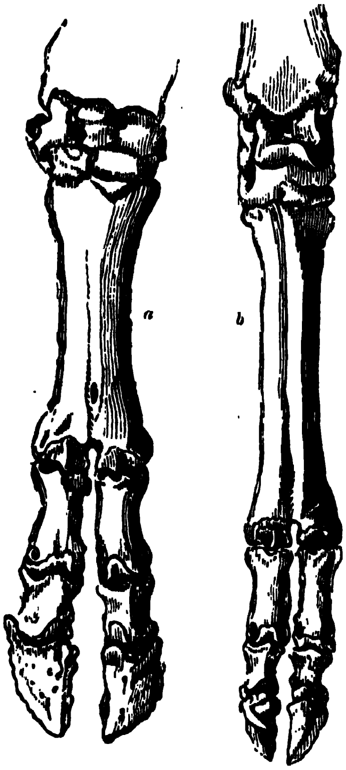
The rest of the skeleton is much like that of the other Ruminants, and the following cuts will give a better idea than words of the construction of the extremities.

The anterior angle of the spine of the scapula is prolonged as in the camels into an acromial apophysis, and the spinal border is rounded; moreover in the Ox the base of the spine towards the neck of the bone is blended with the anterior border. In the pelvis of the Ruminants generally the spinal angle of the ossa ilii is wider and placed more backwards than the external angle, the truncation of which is oblique and nearly continuous to the anterior border of the bone. The pelvis of the Ox may thus be easily distinguished from that of the horse, which has its spinal angle pointed and as forward as the external angle, which last is more truncated, so as to be nearly square. The ischium of the Ox moreover is much more elevated above the cotyloid cavity, the ischial tuberosity is truncated so as to present three angles, and the posterior edge of the pelvis forms a well-marked re-entering angle, whilst in the horse the same part is nearly rectilinear.

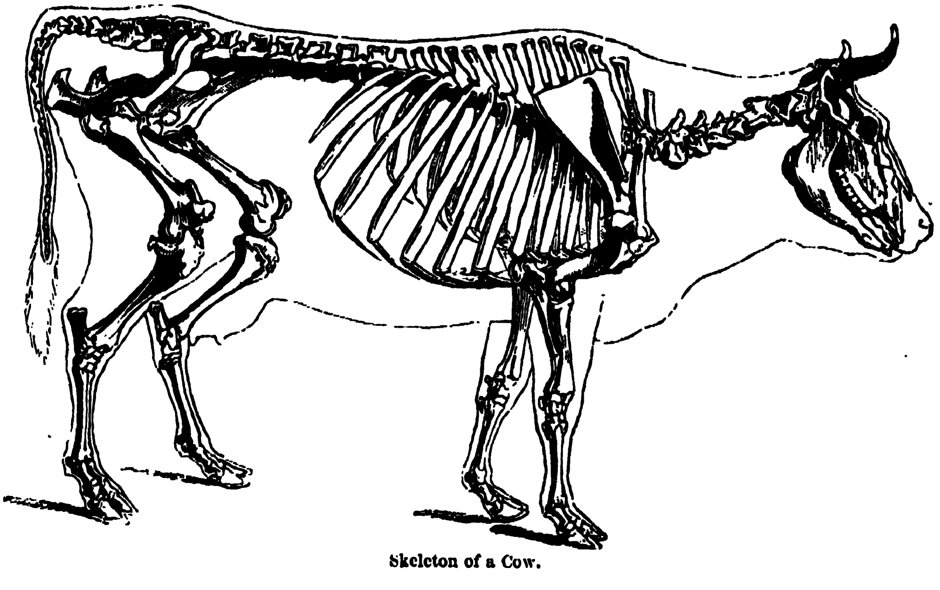
The following table of the number of Vertebræ in the *Boveæ* is given in Mr. Vasey's 'Delineations of the Ox-Tribe,' and he adds that the statements, except that with regard to the Yak, are from his own observations:—

	Cervical.	Dorsal.	Lumber.	Sacral.	Caudal.	Total.
American Bison	7	14	5	5	12	
European Bison	7	14	5	5	19	50
Yak	7	14	5	5	14	45
Gayal (Domestic)	7	14	5	5	16	47
Gayál (Asseel)						
Gyall						
Jungli Gau						
Italian Buffalo						
Indian Buffalo						
Buffalo (in Coll. Surg. Mus.)	7	13	6	5	16	47
Gaur	7	13	6	5	19	50
Domestic Ox	7	13	6	5	21	52
Condore Buffalo						
Manilla Buffalo	7	13	6			
Pegasse						
Arnee						
Cape Buffalo	7	13	6	4	19	49
Zamouse	7	13	6	4	20	50
Banting	7	13	6	4	18	48
Zebu	7	13	6	4	18	48
Galla Ox						
Backeley						
Musk Ox						

The organs of digestion of the Ox are formed on the same type as those of the other *Ruminantia*. The food on passing down the œsophagus enters the large cavity called the ingluvies, or paunch, where it remains till it is moistened with fluid secreted from the walls of this bag. Liquids swallowed by the animal appear to be directed into a second cavity called the reticulum, or honey-comb stomach, into which also the food passes from the first. The food is then returned in the form of little pellets into the mouth, where it is again masticated and moistened with salivary fluid. It once more passes down the œsophagus into a third cavity, the omasum, called the 'many-plies,' from its plicated structure, and finally passes in a pulpy state into the reed, or abomasum, from which it is projected into the intestines.



a, Fore-foot of Ox; *b*, hind foot of the same.



Skeleton of a Cow.

With regard to their food Oxen are eminently herbivorous, for though they will browse upon shrubs and trees, grass and herbage is their staple. No one can watch a cow grazing without observing how perfectly the whole mechanism works together—the tongue sweeping in a wisp of herbage into the vice formed by the cutting-teeth of the lower jaw and the unarmed front of the upper one, and the muscles immediately aiding with the upward jerk to separate the bite from the roots on which it was growing. In a state of domesticated nature, that is, where the animal roams at large and is not stall-fed or confined to what are called artificial grasses, or to artificial food, we are told in 'The Swedish Pan' ('Amæn. Acad.' vol. ii.) that oxen eat 276 plants and refuse 218; that heifers waste away in inclosures where the Meadow-Sweet (*Spiræa Ulmaria*) grows in abundance and covers the ground so that they can scarce make their way through it: "the country people," says the author, "are amazed, and imagine that the Meadow-Sweet affords them no nourishment; whereas the goat which is bleating on the other side of the hedge is not suffered to go in, though he longs to be browsing on this plant, which to him is delicate and nourishing food." The leaves of the Long-Leaved Water-Hemlock (*Cicuta virosa*) are fatal to oxen, whilst the goat feeds heartily and safely upon it. Linnæus found that this plant was the cause of the terrible disease that raged among the horned cattle at Tornea. He had scarcely left the boat which carried him over the river to the fatal meadow before he was convinced. The cattle it appeared died as soon as they left off their winter fodder and returned to grazing; the disease diminished as the summer came on, at which time as well as in the autumn few died. The distemper was propagated irregularly and not by contagion: the cows were driven in the spring to the meadow where Linnæus landed and where he saw plenty of the Long-Leaved Water-Hemlock, and there they died swollen and in convulsions. In other places the plant was scarce. "The least attention will convince us," says Linnæus, "that brutes spurn whatever is hurtful to them, and distinguish poisonous plants from salutary by natural instinct; so that this plant is not eaten by them in the summer and autumn, which is the reason that in those seasons so few cattle die, namely, only such as either accidentally or pressed by extreme hunger eat of it. But when they are let into the pastures in spring, partly from their greediness after fresh herbs and partly from the emptiness and hunger which they have undergone during a long winter, they devour every green thing which comes in their way. It happens moreover that herbs at this time are small and scarcely supply food in sufficient quantity. They are besides more juicy, are covered with water, and smell less strong, so that what is noxious is not easily discerned from what is wholesome. I observed likewise that the radical leaves were always bitten, the others not, which confirms what I have just said. I saw this plant in an adjoining meadow mowed along with grass for winter fodder, and therefore it is not wonderful that some cattle though but a few should die of it in winter. After I left Tornea I saw no more of this plant till I came to the vast meadows near Limmingen, where it appeared along the road; and when I got into the town I heard the same complaints as at Tornea of the annual loss of cattle with the same circumstances." The author of the 'Swedish Pan' also observes that a hungry stomach will often drive animals to feed upon plants that were not intended for them by nature. But whenever this has happened they, if they escape, become more cautious for the future, and acquire a certain kind of experience; and he instances the Monk's-Hood (*Aconitum*), which grows near Fahluna, and is generally left untouched by all the animals that are accustomed to these places; but if foreign cattle are brought thither and meet with this vegetable, they venture to take too large a quantity of it, and are killed. He adds that the cattle that have been reared in the plains of Schonen and Westragothia commonly fall into a dysentery when they come into the woodland parts, because they feed upon some plants which the cattle used to those places have learned to avoid. Meadow-Saffron (*Colchicum autumnale*) is among the plants deleterious to oxen if taken in any large quantity, and Hellebore (*Helleborus*) is also said to be poisonous to them. Yew (*Taxus baccata*) is fatal, as it is to herbivorous quadrupeds generally, the green temptation being probably too strong for cattle kept on short allowance. Actions-at-law in this country have not been uncommon against a defendant for not keeping up bounds or hedges whereby the plaintiff's cattle strayed into places where yew-trees grew, fed on the branches, and so died.

The period of gestation of the cow is nine months. The normal number of the offspring is one, though there are not uncommon instances of the cow bringing forth twins, and rare cases of her producing three and even more at a birth. In the case of twins, if they be male and female apparently, the apparent female is generally barren, and is called a Free Martin (*Taura* probably of Columella, Varro, and the ancient Romans).

Mr. Jesse ('Gleanings of Natural History,' 1838) states that if the cow has twins, one of them a male and the other a female, the latter is always barren; but this is an error. "It is a fact known and I believe almost universally understood," writes John Hunter in his 'Account of the Free Martin,' "that when a cow brings forth two calves, and one of them a bull-calf, and the other to appearance a cow, that the cow-calf is unfit for propagation, but the bull-calf grows up into a very proper bull. Such a cow-calf is called in this country a Free Martin, and is commonly as well known among the farmers as either cow or bull. Although it will appear from the description of this animal that it is a hermaphrodite (being in no respect different from other hermaphrodites), yet I shall retain the term free martin to distinguish the hermaphrodite produced in this way from those which resemble the hermaphrodite of other animals; for I know that in black cattle such a deviation may be produced without the circumstance of twins, and even where there are twins, the one a male the other a female, they may both have the organs of generation perfectly formed."

Professor Owen in his valuable edition of Hunter's 'Observations' (1837) adds a note from Loudon's 'Magazine of Natural History;' which states that Joseph Holroyd, Esq., of Withers, near Leeds, had a cow which calved twins, a bull-calf and a cow-calf. As popular opinion was against the cow-calf breeding, it being considered a Free Martin, Mr. Holroyd was determined to make an experiment of them, and reared them together. In due time the heifer brought forth a bull-calf, and she regularly had calves for six or seven years afterwards. Nor are there wanting other cases of fertility under similar circumstances.

When a cow has twins and they are both bull-calves the calves are in every respect perfect bulls, and if cow-calves they are both perfect cows.

In the 'Nouveau Bulletin des Sciences' is given an account of a cow which produced nine calves at three successive births: first, four cow-calves, in 1817; second, three, two of them females, in 1818; third, two females, in 1819. With the exception of two belonging to the first birth all were nursed by the mother.

The origin of our present breeds of domestic cattle has been a subject of much difference of opinion, arising from the existence of certain cattle in an apparently wild condition, and which have been supposed to be descendants of the gigantic *Urus* described by Cæsar as existing in England during the Roman invasion. The existence also of the remains of the Bison (*Bison priscus*) [BISON] in the Tertiary Beds of Great Britain have also served to confuse this question. As this question is not yet perhaps generally regarded as settled, we shall give the opinions of some of those who have written on the subject.

Colonel Hamilton Smith, who appears to have taken considerable pains in investigating the history of the *Ruminantia* generally, and of the Bovine family particularly, places the fossil species (*Bos primigenius*, Bojanus and Owen) under *Bos* (*Taurus*) *Urus*, considering the wild cattle of Chillingham and other parks as the white variety.

Mr. Swainson, in his 'Classification of Quadrupeds,' observes that all writers agree that the large skulls of oxen found in the more recent formations belonged to a formidable race of these animals which existed in Britain in a wild state; that they belonged without doubt to the species named *Urus* by Cæsar and other ancient writers; and that these skulls not only possess a specific distinction, but exhibit the type of a form essentially different from that of the Domestic Ox. "All these skulls," he continues, "are nearly one-third larger than those of the *Bos Taurus*; they are square from the orbits to the occipital crest, and somewhat hollow at the forehead. The horns, placed at the side of the above crest, show a peculiar rise from their roots upwards; then bending outwards, and then forwards and inwards. No domestic races show this turn; but numerous specimens of inferior sizes, found fossil in the Cornish mines, have this shape, and the wild bull of Scotland, the only example of this type now known to exist, retains it. The domestic oxen, on the contrary, of whatsoever country or breed they may be, have the square concave forehead, with the horns rising from the ends of the frontal ridge. . . . It appears then that the ancient *Urus*, or Wild Bull, was a perfectly wild, savage, and untameable animal. Not only does every account handed down from remote antiquity assure us of this, but it is even verified by the only living example of this form we possess, the *Bos Scoticus*, still preserved in one or two of the northern parks. Although domesticated so far as to live within such precincts without absolute unprovoked violence to its keepers, it retains essentially all the savage characters ascribed to the more powerful species mentioned by the ancients. Like that also it possesses when at a mature age a kind of mane about two inches long, and its throat and breast are covered with coarse hair. These characters, which are never found in the domesticated breeds of oxen, were no doubt much more highly developed in the ancient *Urus*. The second type is the domestic ox; the external characters of which, to use the words of Colonel Smith, are 'absolutely the same as the fossil *Urus*, and the wild breeds differ only in the flexure of the horns.' But though these two types come so near each other in external appearance, nothing can be more different than their moral character; the *Urus*, wild, savage, and untameable, remains with all these propensities unimpaired and undiminished from the period of its first creation down to the present day. The other, tame, harmless, and enduring, has voluntarily submitted to the service of man from the most remote antiquity, and seems to have been a companion of the earliest inhabitants of the earth."

The allusion here to the *Bos Scoticus*, the name for the Chillingham and other wild cattle of this country, is hardly correct. Mr. Vasey, a recent observer, says, in his 'Ox-Tribe,' that they do not exhibit more wildness than most domesticated animals when allowed to roam without restraint; and that their young, when properly reared, are as docile as those of the ordinary domestic cattle. Nor do they possess a mane, as has been frequently asserted. The wild cattle breed with the domestic cattle. The cow goes the same period with young. They have the same number of ribs, and even their white colour at Chillingham is the result of the destruction by order of the owner of all spotted calves that are produced. The following account is given by Mr. Culley, in Bewick, and, as an early description of these animals, is interesting; but it is evidently highly coloured, and has misled those who have relied upon it:—

"Their colour is invariably of a creamy white, muzzle black; the whole of the inside of the ear, and about one-third of the outside, from the tips downwards, red; horns white with black tips, very fine and bent upwards; some of the bulls have a thin upright mane, about an inch and a half or two inches long. At the first appearance of any person they set off in full gallop, and at the distance of two or three hundred yards make a wheel round, and come boldly up again, tossing their heads in a menacing manner: on a sudden they make a full stop, at the distance of forty or fifty yards, looking wildly at the object of their surprise; but upon the least motion being made, they all again turn round and fly off with equal speed, but not to the same distance; forming a shorter circle and again returning with a bolder and more threatening aspect than before, they approach much nearer, probably within thirty yards, when they make another stand, and again fly off; this they do several times, shortening their distance and advancing nearer till they come within ten yards, when most people think it prudent to leave them, not choosing to provoke them further; for there is little doubt but in two or three turns more they would make an attack. The mode of killing them was perhaps the only modern remains of the grandeur of ancient hunting. On notice being given that a wild bull would be killed on a certain day, the inhabitants of the neighbourhood came armed with guns, &c., sometimes to the amount of a hundred horse, and four or five hundred foot, who stood upon walls or got into trees, while the horsemen rode off the bull from the rest of the herd, until he stood at bay, when a marksman dismounted and shot. At some of these huntings twenty or thirty shots have been fired before he was subdued. On such occasions the bleeding victim grew desperately furious from the smarting of his wounds and the shouts of savage joy that were echoing from every side; but from the number of accidents that happened this dangerous mode has been little practised of late years, the park-keeper alone generally shooting them with a rifled gun at one shot. When the cows calve they hide their calves for a week or ten days in some sequestered situation, and go and suckle them two or three times a day. If any person come near the calves, they clap their heads close to the ground, and lie like a hare in form to hide themselves: this is a proof of their native wildness, and is corroborated by the following circumstance that happened to the writer of this narrative, who found a hidden calf, two days old, very lean and very weak. On stroking its head it got up, pawed two or three times like an old bull, bellowed very loud, stepped back a few steps, and bolted at his legs with all its force; it then began to paw again, bellowed, stepped back, and bolted as before; but knowing its intention, and stepping aside, it missed him, fell, and was so very weak that it could not rise, though it made several efforts. But it had done enough, the whole herd were alarmed, and coming to its rescue obliged him to retire; for the dams will allow no person to touch their calves without attacking them with impetuous ferocity. When any one happens to be wounded, or is grown weak and feeble through age or sickness, the rest of the herd set upon it and gore it to death. The weight of the oxen is generally from forty to fifty stones the four quarters; the cows about thirty. The beef is finely marbled and of excellent flavour. Those at Burton-Constable in the county of York were all destroyed by a distemper a few years since. They varied slightly from those at Chillingham, having black ears and muzzles, and the tips of their tails of the same colour: they were also much larger, many of them weighing sixty stones; probably owing to the richness of the pasturage in Holderness, but generally attributed to the difference of kind between those with black and with red ears, the former of which they studiously endeavour to preserve. The breed which was at Drumlanrig in Scotland had also black ears."

Mr. Bell ('British Quadrupeds,' 1839—the 'Ox'), after referring to Griffith's ed. of Cuvier for Colonel Hamilton Smith's interesting and learned dissertation upon the mythology and ancient history of the Ox, says, "Whether the ox exist now or has existed within the range of sound historical testimony, in its original state, or whether, as in the case of the horse, all the instances of the occurrence of wild oxen of this species now on record have not been derived from the domestic race, fortuitously escaped from servitude and become wild, is a question which it is difficult if not impossible satisfactorily to solve. The ancient accounts of the *Urus*, or Wild Ox, declare it to have been an animal of enormous size and great fierceness; and the horns are described as being large, spreading, and acute. In this country and in many parts of the Continent have occurred numerous fossil bones of oxen, with large horns, having the form and direction of those of certain breeds only of our present cattle, particularly of such as are most wild; as for instance the celebrated wild white oxen of Craven, of Chillingham Park, and of Scotland (the *Bos Scoticus* of some authors). I cannot but consider it as extremely probable that these fossil remains belonged to the original wild condition of our domestic ox, an opinion which Cuvier appears to have entertained, who calls the skulls 'Crânes semblables à ceaux d'un bœuf domestique.' They are found only in very recent deposits, frequently in caverns mingled with the remains of various other animals, as in the celebrated cave of Kirkdale, and in different parts of Cornwall and of Devonshire. I have several teeth and some fragments of bones from Kent's Hole, in the latter county, where they were found in the same mass with the remains of the elephant, the rhinoceros, the deer, the bear, and the hyæna. Cuvier however considers that they existed after the destruction of the latter species. It has indeed been attempted to prove that the ancient remains alluded to, together with the Chillingham and Scottish breed, belong to a distinct specific type from the common domestic ox; and some modifications of structure have been cited in proof of this opinion. It does not appear to me however that these modifications are of sufficient value to constitute specific distinction, as they appertain only to parts which are very variable in particular breeds of the domestic cattle; they are, some slight differences in the form and direction of the horns, and the existence in old bulls of a short rudimentary mane and some hair upon the breast. Now, there is certainly no point of sufficient importance to form a specific distinction, even were the form of the horns less variable than they are in our domestic oxen. We require yet a series of well-authenticated and well-directed experiments on the intermixture of the Scottish or Chillingham cattle with the domestic breeds, and the fertile or infertile character of the progeny; which, if the views I have so repeatedly stated be correct, would at once decide the question. Even Colonel Smith himself, a high authority in these matters, although he urges the specific distinction of the two animals, says, 'The character of the domestic oxen is absolutely the same as the fossil, and the wild breeds differ only in the flexure of the horns and external appearance, occasioned by the variations of climate, food, and treatment.' But, it may be asked, do variations of climate, food, and treatment produce specific distinctions? And yet this distinction is, as I have just stated, held both by Colonel Smith and Mr. Swainson. Upon the whole I cannot but believe that the fossil bones belonged to the original stock of our domestic ox, and that the wild white cattle (the *Bos Scoticus* and *Urus Scoticus* of the authors just named) approach so near to it as to leave it a matter of doubt, not whether they all belong to the same species, but whether this breed be the actual remnant of that original stock, or the descendants of domesticated individuals which have resumed in a great degree their wild character from having ceased through many generations to feel the effects of human domination."

In his 'History of British Fossil Mammals,' speaking of the *Bos pimigenius*, Professor Owen says—

"Of this species we have the same examples, short of the still preserved living animal, as of the bison; and it is most satisfactory to find such proof of the general accuracy of the brief but most interesting indications of the primitive mammalian fauna of those regions of Europe, which may be supposed to have presented to the Roman cohorts the same aspect as America did to the first colonists of New England.

"In the same deposits and localities which have yielded remains of the Aurochs (*Bison priscus*) there have been found the remains of another bovine animal, its equal or superior in size, but differing from the Aurochs, precisely as the Roman poets and historians have indicated, by the greater length of its horns.

"The persistent bony supports or cores of the horns likewise demonstrate by their place of origin and curvature, the sub-generic distinction of the great Urus from the bison, and its nearer affinity to the domestic ox; whence we may infer that it resembled the ox in the close nature of its hairy covering, which would make the shaggy coat and the mane of the Aurochs more remarkable by comparison. It is much to be regretted, for the interests of zoology, that the great Hercynian Uri have been less favoured than their contemporary *Bisontes jubati* in the progress of human civilisation, and that no individuals now remain for study and comparison like the Aurochs of Lithuania.

"My esteemed friend Professor Bell, who has written the 'History of Existing British Quadrupeds,' is disposed to believe with Cuvier and most other naturalists, that our domestic cattle are the degenerative descendants of the great Urus. But it seems to me more probable that the herds of the newly conquered regions would be derived from the already domesticated cattle of the Roman colonists of those 'boves nostri,' for example, by comparison with which Cæsar endeavoured to convey to his countrymen an idea of the stupendous and formidable Uri of the Hercynian forests. The taming of such a species would be much more difficult, and his certain mode of supplying the exigencies of the agriculturist, than the importation of the breeds of oxen already domesticated and in use by the founders of the new colonies. And that the latter was the chief if not the sole source of the ox of England, when its soil began to be cultivated under the Roman sway, is strongly indicated by the analogy of modern colonies. The domestic cattle, for example, of the Anglo-Americans have not been derived from tame descendants of the original wild cattle of North America; there, on the contrary, the bison is fast disappearing before the advance of the agricultural settlers, just as the Aurochs and its contemporary the Urus have given way before a similar progress in Europe.

"With regard to the great Urus I believe that this progress has caused its utter extirpation, and that our knowledge of it is now limited to deductions from its fossil or semi-fossil remains."

There seems to be little doubt then that the Fossil Ox (*Bos primigenius*) is entirely extinct, and that all our domestic and wild cattle belong to *Bos Taurus*.

English Bull (*Bos Taurus*), short-horned.

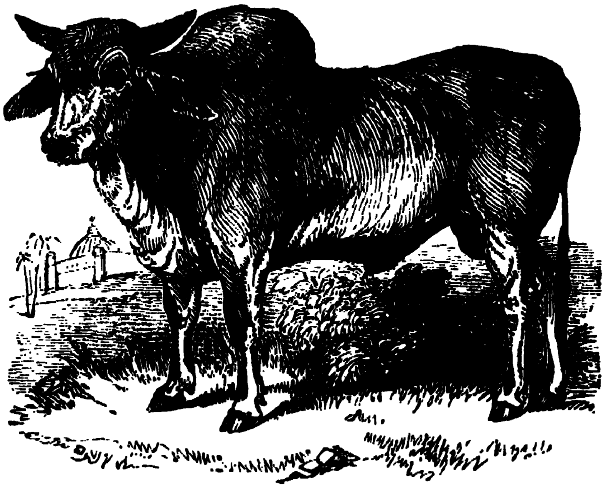
B. Indicus, the Zebu, has the following specific characters:—Forehead convex; withers with a more or less large fleshy hump; dewlap deep, waved; the upper part of the rump shelving very much. Amongst scientific writers this animal has had many designations. It is the *Bos Indicus* of Linnæus, the *Bos domesticus* of Hodgson, the *Bos Taurus Indicus* of Fischer, *Bos Zebu* of J. Brookes, *Bos Taurus Zebu* of Wagner. Varieties or particular breeds have also obtained a number of distinct appellations,—Little Indian Buffalo, Indian Bull, Great Indian Ox, Gun Bullock, Sacred Bull, Madras Ox, Madhu Givi Oxen, Seringapatam Oxen, Two-Humped Zebu, Hornless Zebu, Bucharian Ox, Nepaul Ox, and Javanese Cow.

The domesticated Zebus vary much in their size and the direction of their horns, but are generally distinguished by a fatty elevated hump below the neck and over the withers.

The horns of some are short and suberect (Indian Ox), in others comparatively long and pointed backwards, with an inclination to curve inwards, as in the more common breeds (Zebu). The ears of some are of ordinary size and position (Zebu); in others pendulous (Indian Ox). The dewlap is more or less developed, in some very largely. Their colour varies from a light ashy-gray to a milk-white, and their size from the stature of an ordinary bull to that of a large mastiff. Many of these varieties may be seen in the gardens of the Zoological Society in the Regent's Park. The limbs of all are deer-like and elegant. They "are spread," says Mr. Bennett, "over the whole of southern Asia, the islands of the Indian Archipelago, and the eastern coast of Africa, from Abyssinia to the Cape of Good Hope."

In many parts of India the Zebu is placed under the saddle or harnessed to a carriage, and travels at an easy rate. It must have lost much of its fleetness, if the more ancient writers are to be credited; for they speak of 50 or 60 miles a day as its usual pace, whilst the moderns only allow it 20 or 30 miles. The beef is not bad, but is neither so sweet nor so good as that of the common Ox, the hump always excepted, which when well cooked is very delicate.

The Zebus bear a charmed life among the Hindoos, who venerate them and hold their slaughter to be a sin; though they do not object to work them. There are however some particularly sanctified Zebus, who lead an easy life, wandering about the villages at their ease, and taking their pleasure and their food where they list, if not prevented by the contributions of the devout.



Indian Ox, or Zebu (*Bos Indicus*), large variety.

They may be seen every day wandering at large in the streets of Calcutta eating rice, grain, and flour in the bazaar; and the utmost a native does when he sees them honouring his goods too much, is to urge them by the gentlest hints to taste some of the good things on his neighbour's stall. The superstitious regard for these animals accounts for the use of cow-dung in the representation of objects on the walls. This substance is also collected and dried and used for cooking food, apparently with a religious object in view, as it is used in Calcutta where wood is in abundance.

Mr. Bennett in his work on the 'Gardens and Menagerie of the Zoological Society,' has expressed an opinion that the Zebu is but a variety of the common Ox, but Mr. Vasey observes that the number of the vertebræ and the period of gestation both differ from that of the Ox.

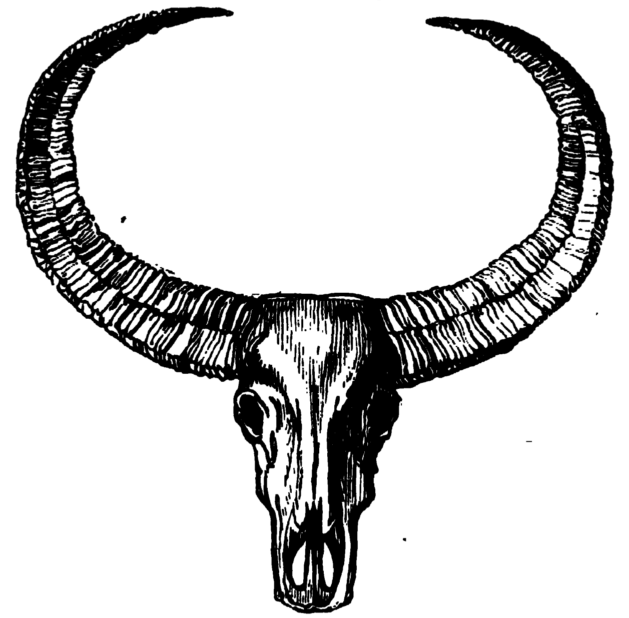
B. Dante, the Dante. Face rather narrow; forehead very flat, with the horns on the side of the high occipital ridge; withers with a small but distinct hump. This animal is not so well known as the preceding. It is the *Bos elegans et parvus Africanus* of Belon; *Juvenca sylvestris* of Alpinus, *Bos Bubalus Africanus* of Brisson; Salam Buffalo, Dwarf Bull, Egyptian Zebu, of various writers. Long in his 'Egypt' says that this animal agrees better with the humped cattle on the ancient Egyptian tombs than with the Zebus. Mr. Whitfield brought a pair of those animals to England. The bull is still living in the gardens of the Zoological Society. He is white, with a few brown specks on the head. The female is yellow-brown, with a very narrow head.

Bubalus. Horns depressed or subtrigonal at the base, inclining upwards and backwards, conical, and bending upwards at the tip on a plane rather in front of the occipital ridge; forehead rather transverse, convex, shelving before and behind; the intermaxillaries elongate, extending back, and between the nasal and cheek-bones; teats in a cross series, the outer one rather before the others.

B. brachycerus, the Zamouse, or Bush Cow. Forehead flat; horns short, thick, depressed at the base; ears very large, strongly fringed on the edge, and with two diverging strongly-fringed lines within; fur short, close, brown. This is the *Bos Bubalus* of Children, and *Bos Caffer* of Ruppell. This animal, according to Dr. Gray, who has described one in the Surrey Zoological Gardens, differs from the buffalo and all other oxen in several important characters, especially in the large size and particular bearding of the ears, and in being totally deficient of any dewlap. It also differs from the buffalo in its forehead being flatter, and quite destitute of the convex form, which is so striking in all the varieties of that animal.

B. Buffalus, the Buffalo. Forehead convex, rounded; horns large, flattened at the base, black on the plane of the face, bent down and recurved at the tip; ears quite half the length of the head, slightly ciliated; fur rough, irregular, bristly, often very far apart, on the face before the eyes two-rowed. This animal is the *Bos Bubalus* of Brisson; the *Bos Bubalis* of Linnæus; Buffle, French; and Büffel, German. A variety was called by Shaw *Bos Arnee*, which is the *Bubalus Arna* of Hodgson.

Mr. B. H. Hodgson, who has by his labours thrown so much light upon Indian zoology, says of the Indian Buffaloes: "The Bhainsa, or Tame Buffalo, is universal in India. The Arna, or Wild Buffalo, inhabits the margins rather than the interior of primæval forests. They never ascend the mountains, and adhere like the rhinoceros to the most swampy sites of the district they inhabit. There is no animal upon which ages of domesticity have made so small an impression as upon the Buffalo, the tame being still most clearly referrible to the wild ones at present frequenting all the great swampy jungles of India. In the wilderness as in the cow-house there is a marked distinction between the long (*macrocerus*) and curved-horned (*spirocerus*) buffaloes.

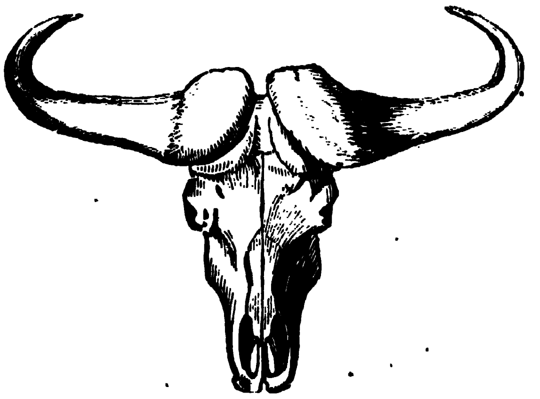


Skull and Horns of the Arnee.

"The Arna ruts in autumn, gestating ten months, and produces one or two young in summer. It lives in large herds, but in the season of love the most lusty males lead off and appropriate several females, with which they form small herds for the time. The Wild Buffalo is fully one-third larger than the largest tame breeds, measuring 10¼ feet from snout to vent, and 6 or 6¼ feet high at the shoulders, and is of such power and vigour as by his charge frequently to prostrate a well-sized elephant. It is remarkable for the uniform shortness of the tail, which does not extend lower than the hock, for the tufts which cover the forehead and knees, and lastly for the great size of its horns. They are uniformly in high condition, so unlike the leanness and angularity of the Domestic Buffalo, even at its best."

The Buffalo has been introduced into Italy, where it is made very useful as a beast of burden, its great strength giving it an advantage over horses and ordinary oxen, in the marshy and swampy districts where the roads are frequently two or three feet deep with mud. A singular fact with regard to them is, that they thrive best in those districts which are most infected with malaria. The Manilla Buffalo is also a variety of this species.

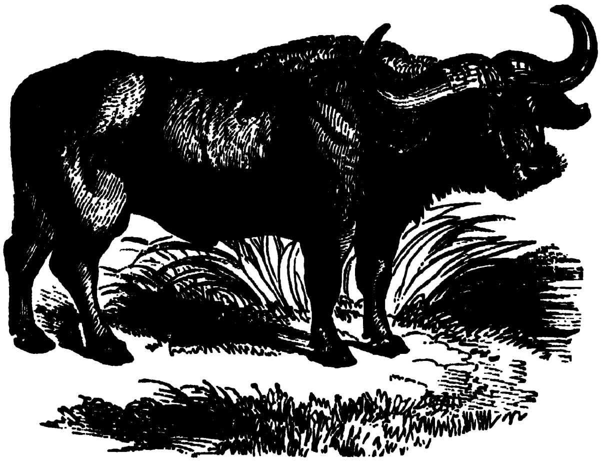
B. Caffer, the Cape Buffalo. Horns black, extremely large, and flattened at their base, where they cover the front, having a direction from within outwards and downwards, and then again elevated at their point; ears rather pendant, and covered by the horns; dewlap large and pendant; skin with harsh hairs an inch long of a deep brown or black colour. Size great, and proportions massive.



Skull of Cape Buffalo (*Bubalus Caffer*).

This is the *Bos Caffer* of Sparmann and other naturalists. Also known by the name of the Cape Ox. It is a native of South Africa.

The Cape Buffalo congregates in large herds. Thunberg and his companions came suddenly upon a mass of 500 or 600, which were grazing in a plain skirted by a wood. The beasts did not see the intruders till they came within three hundred paces, when the whole herd lifted their heads and stood at a gaze. After a while the buffaloes stooped their heads again to feed, and six of the party (three Europeans and three Hottentots), who carried muskets and were accompanied by others armed with javelins, marched up to them within forty paces, when the herd again lifted their heads and were saluted with a volley, which instantaneously dispersed them, leaving their wounded to follow as they could. One of these, an old bull, made the travellers fly, but fell before he reached the wood. This beast was very thick in the body, with short legs, of a dark-gray colour, and almost destitute of hairs. But if a herd may be approached thus safely, a single outlying bull or a wounded one appears to be a most formidable antagonist. The author last quoted was botanising in a wood rather behind his companions, when Auge, the gardener of the expedition who went first, suddenly encountered a large old male buffalo, which was lying down quite alone in a spot of a few square yards free from bushes. No sooner did the beast discover the poor gardener than he rushed upon him with a terrible roar. Auge turned his horse short round behind a great tree, so as in some measure to get out of the sight of the buffalo, which now charged straight towards the sergeant who followed, and gored his horse in the belly so terribly that it instantly fell on its back, with its feet turned up in the air and its entrails hanging out, in which state it lived almost half an hour. In the meantime the gardener and sergeant had climbed up into trees for safety. Thunberg intent upon his botanising, and with his ears filled with the rustling of the branches in the narrow pass where he was against his saddle and baggagé, heard nothing of all this, though so near. But the buffalo had not done yet. The sergeant had brought two horses with him for his journey. One of them, as we have seen, had been already dispatched; the other now stood just in the way of the buffalo as he was going out of the wood. As soon as the infuriated beast saw this second horse he attacked it so furiously that he not only drove his horns into the horse's breast and out again through the very saddle, but threw it to the ground with such violence that it instantly expired, and all the bones of its body were broken. Just as the buffalo was thus engaged with this last horse, Thunberg came up to the opening and beheld the frightful scene. The wood was so thick that he had neither room to turn his horse round, nor to get on one side; he therefore was obliged to take refuge upon a tree into which he climbed, leaving his horse to its fate. But the buffalo had satiated his rage, or did not distinctly see the new object, for after his second exploit he turned suddenly round and went off. Thunberg found his companions half dead with fear, indeed the gardener was so affected that he could scarcely speak for some days after, and the two surviving horses were discovered shivering with fear, and unable to make their escape. ('Travels.')



Cape Buffalo (*Bubalus Caffer*).

Sparrmann ('Voyage to the Cape,' vol. ii.) gives a graphic description of the shooting of one, and of the unconquerable spirit of the animal even in death. We can only find room for the final act of the tragedy. "During his fall, and before he died," writes Sparrmann, "he bellowed in a most stupendous manner; and this death-song of his inspired every one of us with no small degree of joy on account of the victory we had gained: and so thoroughly steeled frequently is the human heart against the sufferings of the brute creation, that we hastened forward in order to enjoy the pleasure of seeing the buffalo struggle with the pangs of death. I happened to be the foremost amongst them; but think it impossible ever to behold anguish, accompanied by a savage fierceness, painted in stronger colours than they were in the countenance of this buffalo. I was within ten steps of him, when he perceived me, and, bellowing, raised himself suddenly again on his legs. I have had reason to believe since, that I was at the time very much frightened; for before I could well take my aim I fired off my gun, and the shot missed the whole of his huge body, and only hit him in the hind legs, as we afterwards discovered by the size of the ball. Immediately upon this I fled away like lightning in order to look out for some tree to climb up into." The same author gives the following as the measurement of a buffalo:—Length 8 feet, height 5½ feet, and the fore legs 2½ feet long: the larger hoofs 5 inches over. The distance between the points of the horns he states to be frequently 5 feet. They are black, and the surface, to within about a third part of them, measured from the base, is very rough and craggy. A very lively account of a buffalo-hunt is also given by Bruce. He guesses the weight of a bull that he assisted in killing at nearer 50 than 40 stones. The horns, from the root, following the line of their curve, were about 52 inches, and nearly 9 inches where thickest in circumference.

The Cape Buffalo delights in wallowing in the mire, and when heated by hunting throws himself into the first water he reaches.

The flesh is described by some as good and high flavoured, by others as ill-grained and coarse. The difference in these accounts is probably to be traced to the sex, age, and condition of the animals eaten. The rhinoceros-like hide is much sought after for harness, &c.

The horns of the domesticated oxen of the Cape grow to an enormous size.

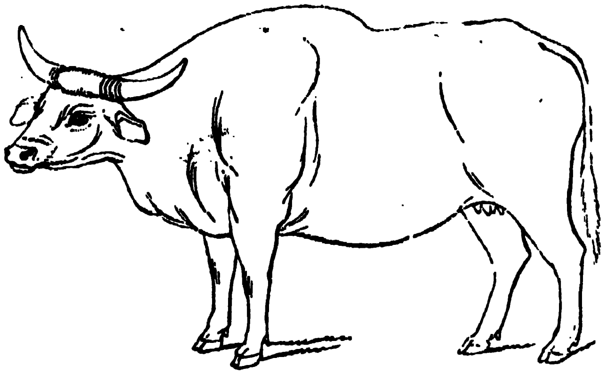
Anoa. Horns subtrigonal, nearly parallel, round at the tip, depressed at the base, and slightly keeled on the inner edge, straight nearly on the plane of the face on the hinder edge of the frontal ridge. *A. depressicornis*, the Anoa. Reddish-brown, with three small white spots on the cheek. Male black, spot on cheek white. Female and young brownish-black. This animal was first described by Colonel H. Smith from a head and horns in the College of Surgeons. [ANOA.] He regarded it as an antelope. Since then Quoy and Gaimard have figured the whole animal, and a specimen exists in the British Museum. This was brought from Celebes.

Bibos. Horns depressed at the base, directed outwards, posterior on the hinder ridge of the frontal bone, which is often very prominent, recurved at the tips. Withers high, keeled, supported by the spinous processes of the dorsal vertebræ, and suddenly lower behind. The intermaxillaries are short and triangular, and do not reach to the nasals. There are three species which Professor Lundevall regards as subvarieties of a variety of the common bull. *B. frontalis*, the Gayál. It is the *Bos frontalis* of Lambert; the *Bos Gaycus* of Colebrooke; Gavaya, Sansc.; Gavaï or Gayál, Hind.; Gobaygoru, Beng.; Gaujangalí, Pers.; Methana, Mountaineers (Cúcís, &c.) east of Silhet; Shiál, Mountaineers (Cúcís) east of Chatgaon; J'hongnua, Mugs; Núnec, Birmas; Gauvera, Ceylon.

It is nearly of the size and shape of the English bull. It has short horns, which are distant at their bases, and rise in a gentle curve directly out and up: a transverse section near the base is ovate, the thick end of the section being on the inside. The front is broad, and crowned with a tuft of lighter coloured long curved hair. The dewlap is deep and pendant. It has no mane nor hump, but a considerable elevation over the withers. The tail is short, the body covered with a tolerable coat of straight dark-brown hair; on the belly it is lighter coloured; and the legs and face are sometimes white. (Roxburgh.)

Dr. Buchanan states that the cry of the Gayál has no resemblance to the grunt of the Indian Ox; but a good deal resembles that of the buffalo. It is a kind of lowing, but shriller, and not near so loud as that of the European Ox. To this the Gayál, in Dr. Buchanan's opinion, approaches much nearer than it does to the buffalo. Mr. Macrae states that the Gayál is found wild in the range of mountains that form the eastern boundary of the provinces of Aracan, Chittagong, Tippera, and Silhet. The Cúcís, or Lunetas, a race of people inhabiting the hills immediately to the eastward of Chittagong, have herds of them in a domesticated state. The animal is called Gabay in the Hindoo 'Sástra,' but seems however to be little known beyond the limits of its native mountains, except to the inhabitants of the provinces above mentioned. The same author informs us that the Gayál is of a dull heavy appearance; but at the same time of a form that indicates much strength and activity, like that of the wild buffalo. Its disposition is gentle; even in the wild state on its native hills it is not considered dangerous, never standing the approach of man, much less sustaining his attack. The Cúcís hunt the wild ones for the sake of their flesh. The Gayál is a forest animal, and prefers the tender shoots and leaves of shrubs to grass; it never wallows in mud like the buffalo. It is domesticated by the Cúcís, but does not undergo any labour. The cow goes 11 (?) months with young, gives but little milk, and does not yield it long; but that little is remarkably rich, almost equalling cream, which it resembles in colour; the Cúcís however do not make any use of the milk, but rear the Gayáls entirely for their flesh and skins, of which last, or rather their hides, they form their shields. These domesticated herds roam at large in the forests near their village during the day, but return of their own accord at evening, being early taught to do this by being fed when young every night with salt, of which these animals are very fond. The Hindoos, in the province of Chittagong, will not kill this Gayál (their Gabay), which they hold in equal veneration with the cow, but they hunt and kill another Gayál (As'l Gayál or Seloï) as they do the wild buffalo. The form of the animal, and the way in which it carries its head, will be understood from the following figure, which is reduced from that by a native artist, prefixed to

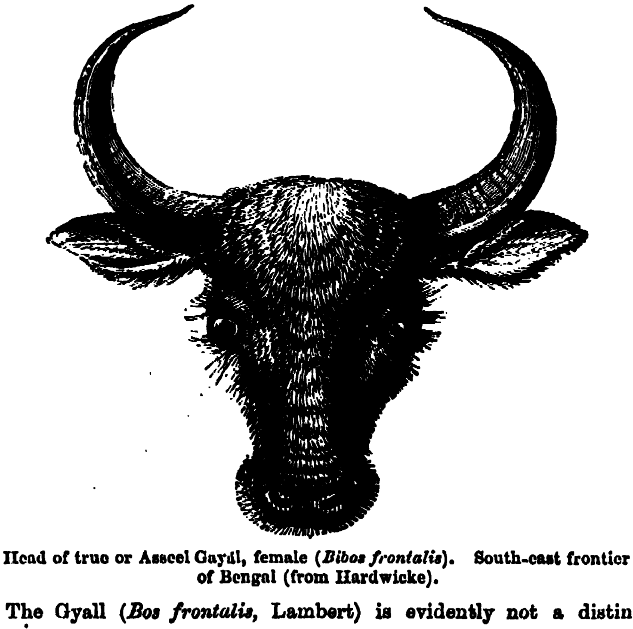
Mr. Colebrooke's paper ('Asiatic Researches,' vol. viii.), to which we refer the reader for further interesting particulars.



The Gayál (*Bibos frontalis*).

Mr. Bird proved that the Gayál will breed with the common Indian bull. He brought a domesticated female Gayál from Chittagong to Dacca, directed a common bull (of the breed Déswáli, a Zebu of the common kind found in the middle districts of Bengal), which the female received upon being blinded with a cloth thrown over her eyes. The offspring was a cow resembling mostly the Gayál mother; and from that cow, impregnated by a bull of the same common breed, another cow was produced, which also had grown up, and was in calf by a common bull when Mr. Bird wrote his account. ('Asiatic Researches,' vol. viii.)

General Hardwicke gives a figure of the head of the true wild Gayál, or as the natives term it, the Asseel Gayál (a female), from the south-east frontier of Bengal. The space between the points of the horns was 14 inches.

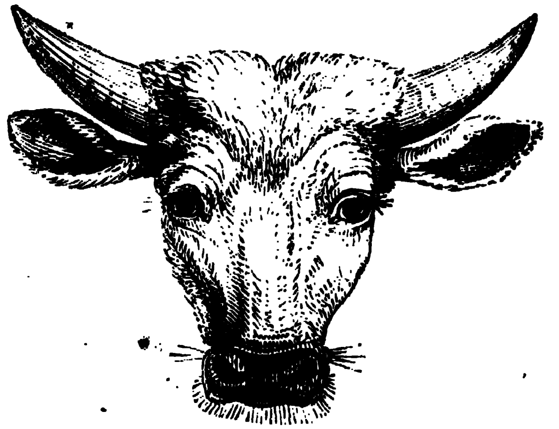


Head of true or Asseel Gayál, female (*Bibos frontalis*). South-east frontier of Bengal (from Hardwicke).

The Gyall (*Bos frontalis*, Lambert) is evidently not a distinct species.

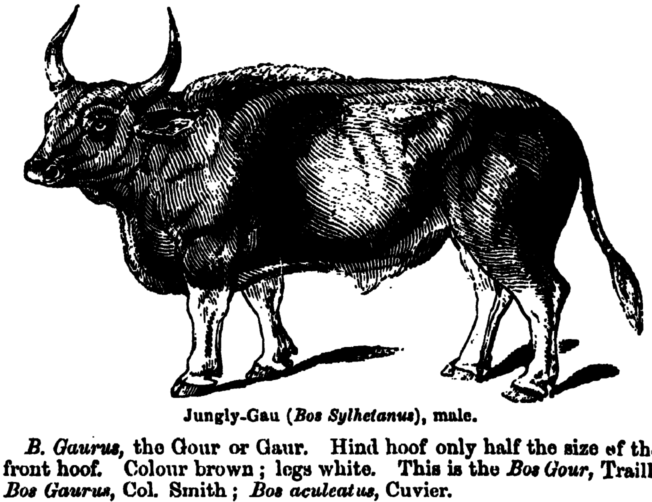
Mr. Lambert observes that the hair of the hide is soft; there is no crest; the lower lip is white at the apex, and bristled with hairs. The band of the forehead, including the bases of the horns, is lead-colour; the horns themselves are pale. Length from the tip of the nose to the end of the tail 9 feet 2 inches; from the tip of the hoof of the fore foot to the top of the rising of the back 4 feet 1¼ inches; from the tip of the hoof of the hind leg to the highest part of the rump 4½ feet.

Mr. Harris, in his letter to Mr. Lambert, after identifying his animal with Mr. Lambert's drawing, writes thus:—"The animal . . . which I have kept and reared these last seven years, and know by the name of the Gyall, is a native of the hills to the north-east and east of the Company's province of Chittagong, in Bengal, inhabiting that range of hills which separates it from the country of Aracan. The male Gyall is like our bull in shape and appearance, but I conceive not quite so tall; is of a blackish-brown colour; the horns short, but thick and strong towards the base, round which and across the frons the hair is bushy and of a dirty-white colour; the chest and forehead are broad and thick. He is naturally very bold, and will defend himself against any of the beasts of prey. The female differs little in appearance; her horns are not quite so large, and her make is somewhat more slender; she is very quiet, is used for all the purposes of the dairy, as also (I have been informed by the natives) for tilling the ground, and is more tractable than the buffalo. The milk which these cows give has a peculiar richness in it, arising, I should conceive, from their mode of feeding, which is always on the young shoots and branches of trees in preference to grass. I constantly made it a practice to allow them to range abroad amongst the hills and jungles at Chittagong during the day to browse, a keeper attending to prevent their straying so far as to endanger losing them. They do not thrive in any part of Bengal so well as in the aforementioned province and in the adjoining one, Tipperah, where I believe the animal is also to be found. I have heard of one instance of a female Gyall breeding with a common bull."



Head of Gyall (*Bos frontalis*). 'Linn. Trans.'

The Jungly-Gau, Bœuf des Jongles of M. Duvaucel, *Bos Sylhetanus* of F. Cuvier, is not a distinct species. Dr. Gray says that Duvaucel's drawing was taken from a hybrid specimen bred between a domestic Gyall and a Zebu. It was never alive in Paris, nor seen alive by M. Duvaucel.



Jungly-Gau (*Bos Sylhetanus*), male.

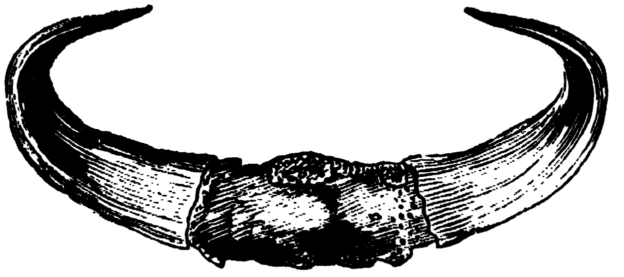
B. Gaurus, the Gour or Gaur. Hind hoof only half the size of the front hoof. Colour brown; legs white. This is the *Bos Gour*, Traill; *Bos Gaurus*, Col. Smith; *Bos aculeatus*, Cuvier.

Dr. Traill remarks that the only animal which appears to have affinity with the Gour is the *Bos Gavæus* of Colebrooke, but the very different form of its head, the presence of a distinct dewlap, and the general habit of the Gaijal or Gayál, distingish it from the Gour. Captain Rogers assured Dr. Traill that neither the descriptions in Mr. Colebrooke's communication nor the figure of the Gayál that accompanies them had any greater resemblance to the Gour than that general one which subsists between all the animals of this genus.

The size of the animal is considerable. Dr. Traill gives the dimensions of one not fully grown, which measured from tip of nose to end of tail 11 feet 11¾ inches; from the hoof to the withers 5 feet 11¾ inches; and from the withers to the sternum 3 feet 6 inches. "The limbs have more of the form of the deer than any other of the bovine genus."

The Gour, according to Captain Rogers, occurs in several mountainous parts of Central India, but is chiefly found in Myn Pât or Mine Paut, a high insulated mountain with a tabular summit, in the province of Sergojah, in South Bahar. "This table-land is about 36 miles in length by 24 or 25 miles in medial breadth, and rises above the neighbouring plains probably 2000 feet. The sides of the mountain slope with considerable steepness, and are furrowed by streams that water narrow valleys, the verdant banks of which are the favourite haunts of Gours. On being disturbed they retreat into the thick jungles of saul-trees which cover the sides of the whole range. The south-east side of the mountain presents an extensive mural precipice from 20 to 40 feet high. The rugged slopes at its foot are covered by impenetrable green jungle, and abound with dens formed of fallen blocks of rock, the suitable retreats of tigers, bears, and hyenas. The western slopes are less rugged, but the soil is parched, and the forests seem withered by excess of heat. The summit of the mountain presents a mixture of open lawns and woods. There were once twenty-five villages on Myn Pât, but these have been long deserted, on account of the number and ferocity of the beasts of prey. On this mountain however the Gour maintains his seat. The Indians assert that even the tiger has no chance in combat with the full-grown Gour, though he may occasionally succeed in carrying off an unprotected calf. The Wild Buffalo abounds in the plains below the mountains, but he so much dreads the Gour, according to the natives, that he rarely attempts to invade its haunts; and the hunting-party only met with three or four urnas on the mountain. The forests which shield the Gour abound however with Hog-Deer, Saumurs (Sambur Deer), and Porcupines." Captain Rogers, who furnished the above account, hunted the Gour in these wild and romantic retreats, and the animal, it appears, when hit faces his adversary, ready to do battle. A short bellow, imitated best by the syllables ugh-ugh, was the only cry heard from the Gour, and that not until after it had been wounded. August is the month in which the calf is generally dropped, and the period of gestation is twelve months. The large quantity of milk given by the cow is averred to be occasionally so rich as to cause the calf's death. The first year the native name of the bull-calf is Purórah; the cow-calf is called Paréeah; and the full-grown cow Goúrin. The Gours herd together in parties varying from ten to twenty; they browse on the leaves and tender shoots of trees and shrubs, and also graze on the banks of the streams. In the cold weather the saul-forests are their places of concealment, and the heats bring them out to feed in the green lawns and valleys. They do not it seems wallow in swamp and mire like the Buffalo. If the natives are to be credited the Gour will not brook captivity; even if taken very young the mountain-calf droops and dies. ('Edinburgh Philosophical Journal,' vol. xi.) Mr. Hodgson says it is exceedingly difficult to rear the Gour in confinement, although attempts are constantly being made by the Court of Nepaul.

General Hardwicke ('Zoological Journal,' vol. iii.) gives a figure of a pair of horns of the "*Bos Gour*, or wild bull of the mountainous district of Ramgurh, and table-land of Sirgoojahs," from which our cut is taken. The Gour to which they belonged was killed, as General Hardwicke believed, by the same hunting-party described by Captain Rogers, and they were presented to the General by the principal member of that party, Major Roughsedge. These horns were 15 inches between the tips.



Horns of Gour (*Bos Gour*). Hardwicke.

B. Banting, the Banting, or Sumatran Ox. Colour black, distinct large spot on rump, and legs white. This is the *Bos Banting* of Sir Stamford Raffles, *Bos leucoprymnus* of Quoy and Gaimard, *Bos Sondaicus* of Müller. It is a native of Java, Borneo, and Bali. There is a stuffed specimen and skeleton in the British Museum. Vasey in his 'Ox-Tribe,' has given a figure, and observes that it "bears some resemblance to the Gour, but in the skeleton of the Gour the sacrum consists of 5 vertebræ and the tail of 19, while in the skeleton of the Banting the sacrum consists of but 4 vertebræ and the tail of 18."

The next genus is *Bison*, of which there are two species, one European, the other American. [BISON.]

Poëphagus. Horns subcylindrical, curved outward on the front of the occipital ridge; nose hairy, with a narrow bald muffle between the nostrils; hoofs moderately thick, not dilated or expanded on the outer side, square and straight in front; tail moderate, not reaching to the hocks, and covered with long hair; teats four, narrowing behind. There is but one species, *P. grunniens*, the Yak, or Sarlyk. It is black; the back and tail often white. It is the *Bos grunniens* of Linnæus; *Bos Poëphagus* of Colonel H. Smith. It has also been called the Grunting Ox, the Grunting Bull, Svora-Goy, and Bubul. There are several varieties, called the Noble Yak, the Plough Yak, the Ghainorik, and Wild Yak. The following notices of the Yak are given in the Catalogue of the British Museum:—

"The Yaks dislike the warmth of summer, and hide themselves in the shade and water; they swim well; both sexes grunt like a pig. The calves are covered with rough black curled hair, like a curled haired dog. When of three months old they obtain the long hair on the body and tail. They willingly live with the common cows, and breed with them. The long white hairs of the tail are dyed red to form the tufts of hair on the caps of the Chinese. (Pallas, 'Act. Acad. Petrop.' 1777, 250.)

"The Yaks used for the plough are ugly and short-legged, and hold their heads very low. The beautiful long silky hair hanging from below the belly is almost if not entirely wanting in them, no less than the bushy tail, which their avaricious owners commonly cut off as an article of trade. They are guided by the nose. (Hoffmeister, 'Travels in Ceylon,' &c., 441.)

"The Yak-Ox used in riding is an infinitely handsomer animal. It has a stately hump, a rich silky hanging tail nearly reaching the ground, twisted horns, a noble bearing, and an erect head (p. 441). They are very shy, and kick with their hind feet, turning their head round perpetually, as if about to gore their riders (p. 443).

"Our broad-footed Yak-Ox is the beast with the thick silky white fringe under the body, and the bushy tail, both of which sweep the ground. . . . . As the steepness increased, these poor animals began to moan, or rather grunt, in the most melancholy manner, and this unearthly music gradually rose to such a violent rattle, that driven rather by its irksome sound than by the discomfort of our saddleless seat, we dismounted at the end of the first half-hour (p. 443)."

The Yak, or Chauri Gau, inhabits all the loftiest plateaus of high Asia, between the Altai and the Himalaya, the Belur Tag, and the Peling Mountains, and is found tame as well as wild. It cannot live on the south side of the Himalaya beyond the immediate vicinity of the snow, where the tribes of Cachars on the juxta-nivean regions of the sub-Himalayas rear large herds of it, and cross-breed with the common-ox. They rut in winter, and produce young in autumn. Cœcum simple, not sacked, nor banded, four inches long; ribs 14 or 15 pairs; true dorsal ridge confined to the withers; dewlap none. (Hodgson.)

Ovibos. Horns very wide, and touching each other at their base, then applied to the sides of the head, and having the points suddenly turned up; no naked muzzle, and no furrow on the upper lip; chanfrein narrow at the end, very square, resembling that of the sheep; ears short; limbs robust; tail very short.

O. moschatus, the Musk Ox. Size of Highland cattle; horns broad at origin, covering the brow and whole crown of the head, and touching each other throughout from before backwards. As each horn rises from its flatly convex base, it becomes round and tapering, curving directly downwards between the eye and the ear, until it reaches the angle of the mouth, when it turns upwards in the segment of a circle to above the level of the eye; for half its length it is dull, white, and rough, and beyond smooth and shining; near the point it becomes black.

Musk-Ox (*Ovibos moschatus*).

General colour of the hair brown, long, matted, and rather curled on the neck and between the shoulders, where it is rather grizzled, on the back and hips long but lying smoothly; on the shoulders, sides, and thighs it is so long as to hang down below the middle of the leg. There is on the centre of the back a mark of a soiled brownish-white, called by Captain Parry the saddle. On the throat and chest the hair is very straight and long, and together with the long hair on the lower jaw, hangs down like a beard and dewlap. The short tail is concealed by the fur of the hips. There is a large quantity of fine brownish ash-coloured wool or down among the hair covering the body. The hair on the legs is short, dull brownish-white, unmixed with wool. The hoofs are longer than those of the Caribou, but so similar in form that it requires the eye of a practised hunter to distinguish the impressions. In the cow, which is smaller than the bull, the horns are smaller, and their bases, instead of touching, are separated by a hairy space. The hair on the throat and chest is also shorter.

This is the Bœuf Musqué of Jeremie; Musk-Ox of Drage, Dobbs, Ellis, Pennant, Hearne, and Parry; *Bos moschatus* of Gmelin, Sabine, and Richardson (Parry's 'Second Voyage'); Mateeh Moostoos (Ugly Bison) of the Cree Indians; Adgiddah-yawseh (Little Bison) of the Chepewyans and Copper Indians; and Oomingmak of the Esquimaux.

The Barren Lands of America lying to the northward of the 60th parallel are the principal habitations of the Musk-Ox. Tracks were once seen by Hearne within a few miles of Fort Churchill, in lat. 59°; and he saw many in his first northern journey, in about lat. 61°. Richardson was informed that they do not now come so far to the southward even on the Hudson's Bay shore; and he adds that farther to the westward they are rarely seen in any numbers lower than lat. 67°, although, from portions of their skulls and horns which are occasionally found near the northern borders of the Great Slave Lake, he thinks it probable that they ranged at no very distant period over the whole country lying between that great sheet of water and the Polar Sea. He had not heard of their having been seen on the banks of Mackenzie's River to the southward of Great Bear Lake, and he states that they do not come to the south-western end of that lake, although they existed in numbers on its north-eastern arm. "They range," continues he, "over the islands which lie to the north of the American continent, so far as Melville Island, in lat. 75°, but they do not, like the rein-deer, extend to Greenland, Spitzbergen, or Lapland. From Indian information we learn that to the westward of the Rocky Mountains which skirt the Mackenzie there is an extensive tract of barren country, which is also inhabited by the musk-ox and rein-deer. It is to the Russian traders that we must look for information on this head; but it is probable that, owing to the greater mildness of the climate to the westward of the Rocky Mountains, the musk-ox, which affects a cold barren district, where grass is replaced by lichens, does not range so far to the southward on the Pacific coast as it does on the shores of Hudson's Bay. It is not known in New Caledonia nor on the banks of the Columbia, nor is it found on the Rocky Mountain ridge at the usual crossing places near the sources of the Peace, Elk, and Saskatchewan rivers. It is therefore fair to conclude that the animal described by Fathers Marco de Niça and Gomara as an inhabitant of New Mexico, and which Pennant refers to the musk-ox, is of a different species. The musk-ox has not crossed over to the Asiatic shore, and does not exist in Siberia, although fossil skulls have been found there of a species nearly allied, which has been enumerated in systematic works under the name of *Ovibos Pallantis*. The appearance of musk-oxen on Melville Island in the month of May, as ascertained on Captain Parry's first voyage, is interesting, not merely as a part of their natural history, but as giving us reason to infer that a chain of islands lies between Melville Island and Cape Lyon, or that Wollaston and Banks' Lands form one great island, over which the migrations of the animals must have been performed. The districts inhabited by the musk-ox are the proper lands of the Esquimaux; and neither the northern Indians nor the Crees have an original name for it, both terming it Bison with an additional epithet."

Sir. John Richardson, who had the best opportunities of coming at the truth, informs us that the country frequented by the Musk-Ox is mostly rocky, and destitute of wood, except on the banks of the larger rivers, which are more or less thickly clothed with spruce-trees. Their food, he tells us, is similar to that of the Caribou, grass at one season and lichens at another; and the contents of its paunch are eaten by the natives with the same relish as that with which they devour the 'nerrooks' of the Caribou. The dung is voided in round pellets, which are larger than those which come from the Caribou. The animal runs fast, short as are its legs, and hills and rocks are easily climbed by this ox of the northern deserts. One pursued by Richardson's party on the banks of the Coppermine River scaled a lofty sand-cliff with so great a declivity that they were obliged to crawl on hands and knees to follow the chase. The musk-oxen assemble in herds of from twenty to thirty, are in their rut about the end of August and beginning of September, and bring forth one calf about the latter end of May or beginning of June. Hearne accounts for the few bulls which are seen by supposing that they kill each other in their contests for the cows.

Richardson thus graphically describes the terror of a huddled herd:—"If the hunters keep themselves concealed when they fire upon a herd of musk-oxen, the poor animals mistake the noise for thunder, and, forming themselves into a group, crowd nearer and nearer together as their companions fall around them; but should they discover their enemies by sight, or by their sense of smell, which is very acute, the whole herd seek for safety by instant flight. The bulls however are very irascible, and particularly when wounded, will often attack the hunter, and endanger his life unless he possesses both activity and presence of mind. The Esquimaux, who are well accustomed to the pursuit of this animal, sometimes turn its irritable disposition to good account; for an expert hunter having provoked a bull to attack him, wheels round it more quickly than it can turn, and by repeated stabs in the belly puts an end to its life."

Mr. Jeremie, who first brought the animal into notice, carried some of its wool to France, where some stockings were made of it, said to have been equal to the finest silk. Sir John Richardson says that this wool resembles that of the Bison, but is perhaps finer, and would in his opinion be highly useful in the arts, if it could be procured in sufficient quantity. The same author informs us that when the animal is fat its flesh is well tasted, and resembles that of the Caribou, but has a coarser grain. The flesh of the bulls is high flavoured, and both bulls and cows when lean smell strongly of musk, their flesh at the same time being very dark and tough, and certainly far inferior to that of any other ruminating animal in North America. The carcass of a Musk-Ox weighs, exclusive of the offal, about three hundred-weight, or nearly three times as much as a Barren-Ground Caribou, and twice as much as one of the Woodland Caribou. (Richardson, 'Fauna Borealia-Americana.')

Budorcas. Muzzle hairy, with a small naked muffle only edging the nostrils; ears narrow, pointed. The fur consists of short, harsh, adpressed hair; the tail is short, very depressed, and hairy, like the tail of a goat; the head is large and heavy; the lips taper, and are clad with hair like sheep; the horns are round, smooth, lunate; they are nearly in contact on the top of the head: their direction is vertically upward, then horizontally outward, or to the sides, and then almost as horizontally backward; the limbs short and straight; the hoofs broad. The only species of this genus is the *B. taxicola*, the Takin. It is the *Nemorhædus* of Turner. It is an inhabitant of the Eastern Himalaya. It is called Takin by the Mishmis, and Ken by the Khamtis. There has been some difference of opinion as to the proper position of this animal, but we have followed Dr. J. E. Gray in placing it amongst the *Boveæ*.

Fossil Boveæ.

Remains of oxen and deer occur abundantly in the Tertiary Beds, with extinct species of existing genera of *Pachydermata*, such as the elephant, rhinoceros, hippopotamus, and horse, the extinct genus *Mastodon*, and large *Carnivora*, as the tiger, hyæna, and bear.

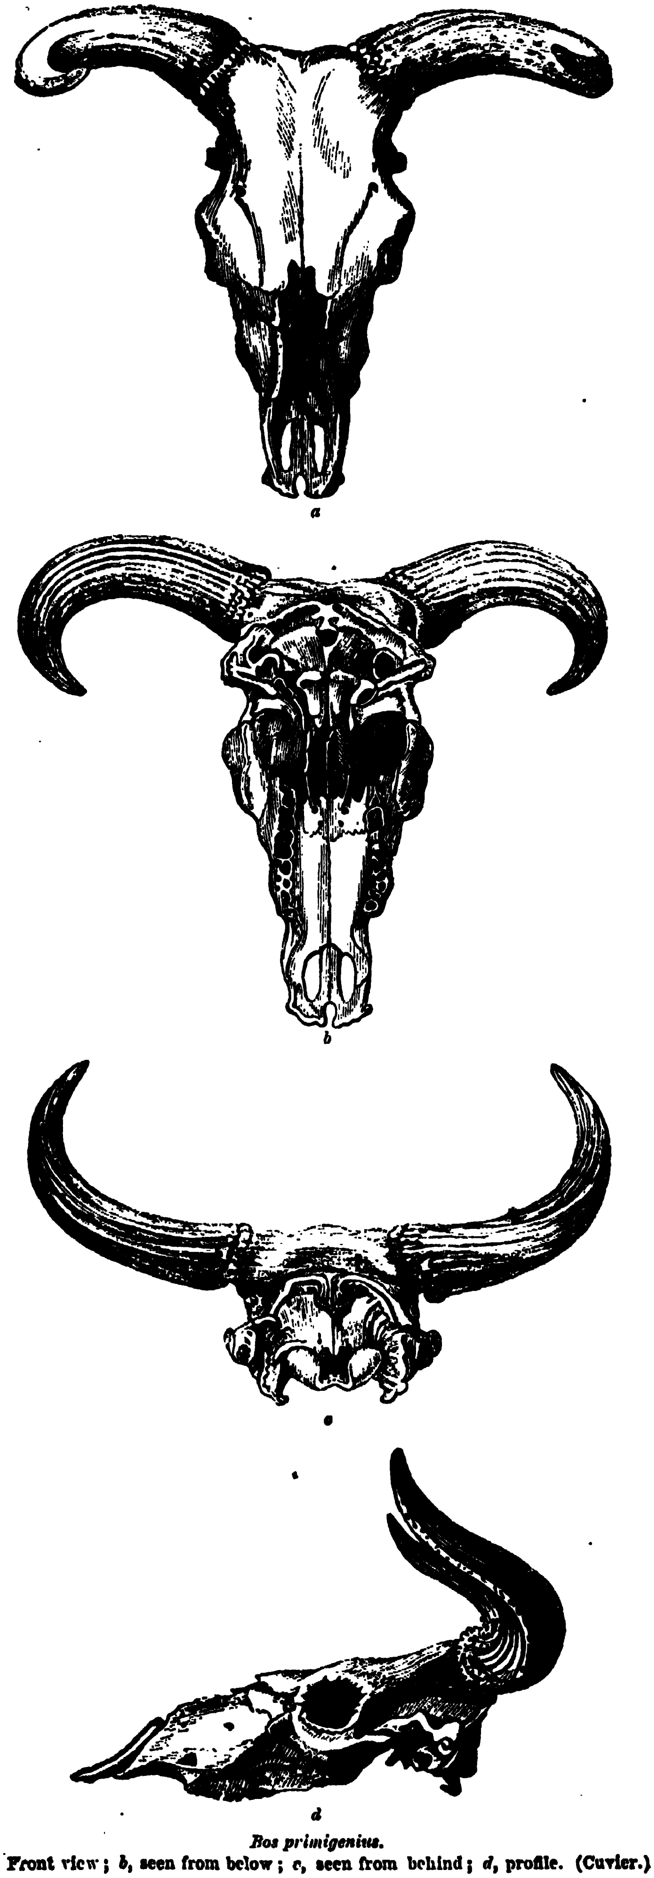
The most interesting of these is the *Bos primigenius*.

Mr. Woods, in a paper on some fossil bones found in Wiltshire, says, "It has occasioned some speculation among zoologists to appropriate to the large herbivorous animals, of which these skulls and scattered bones are now the only vestiges, their proper place in the system of nature. Cuvier however has fixed their characters, and has declared them to resemble the skulls of the present oxen so closely, that there can be little doubt of their having belonged to the stock from which the latter have all proceeded; these having however degenerated in size, and varied from them and from each other in minor points, owing to differences in climate, food, and other causes depending upon domestication, their magnitude is at least one-third greater than that of the largest breed of modern oxen, and their horns are much more massive."

We have seen that Professor Owen is of opinion that the *Bos primigenius* is a distinct species from the Common Ox. That it is distinct from the Bison or Aurochs was pointed out by Bojanus, at the same time we have abundant evidence that it existed in Great Britain with the Aurochs, with the bones of which its remains are found constantly associated. "The characters of *Bos primigenius*," says Professor Owen, "as contrasted with the *Bison priscus*, may be advantageously studied in the magnificent specimen of an entire skull, from near Athol in Perthshire, now in the British Museum. The concave forehead, with its slight median longitudinal ridge; the origin of the horns at the extremities of the sharp ridge which divides the frontal from the occipital regions; the acute angle at which these two surfaces of the cranium meet to form the above ridge, all identify this specimen with the *Bos primigenius* described by Cuvier, Bojanus, and Fremery. The cores of the horns bend at first slightly backward and upward, then downward and forward, and finally inward and upward, describing a graceful double curvature; they are tuberculate at the base, moderately impressed by longitudinal grooves, and irregularly perforated. The skull is one yard in length, and the span of the horn-cores is 3 feet 6 inches; but other British specimens of the *Bos primigenius* have shown superior dimensions of the bony supports of the horns. The breadth of the forehead between the horns is 10½ inches; from the middle of the occipital ridge to the back part of the orbit it measures 13 inches; the length of the series of the upper molar teeth is 6½ inches, the breadth of the occipital condyles is 6 inches."

The difference between the *B. primigenius* and the domestic ox is seen most in its diminutive size and the comparative shortness as well as fineness of its horns. Specimens of *B. primigenius* have been found by Mr. John Brown in the London Clay of Clacton, on the Essex coast, by Mr. H. Woods in the bed of the Avon, by Mr. Wickham Flower in the London Clay of Herne Bay, and in many other places.

In addition to this species Professor Owen describes another fossil species which he has named *B. longifrons*. The first known specimen



Bos primigenius.

Front view; *b*, seen from below; *c*, seen from behind; *d*, profile. (Cuvier.)

of this species was obtained by John Hunter from a bog in Ireland, and was described by Professor Owen as a distinct species. Other specimens have since been brought to light. Dr. Robert Ball described, in the 'Proceedings of the Royal Irish Academy,' for 1839, remains of this species, obtained from considerable depths in bogs in Westmeath, Tyrone, and Longford. Remains of it have also been found in Essex, Middlesex, Devonshire, and other parts of England.

Of this species Prosessor Owen says, "It has been remarked in a former section that the domesticated descendants of a primitive wild race of cattle were more likely to be met with in the mountains than in the lowlands of Britain, because the aborigines, retaining their ground longest in the mountain fastnesses, may be supposed to have driven thither such domestic cattle as they possessed before the foreign invasion, and which we may presume therefore to have been derived from the subjugation of a native species of *Bos*.

"In this field of conjecture the most probable one will be admitted to be that which points to the *Bos longifrons* as the species which would be domesticated by the aborigines of Britain before the Roman invasion. Had the *Bos primigenius* been the source we might have expected the Highland and Welsh cattle to have retained some of the characteristics of their great progenitors, and to have been distinguished from other domestic breeds by their superior size and the length of their horns. The Kyloes and the Runts are, on the contrary, remarkable for their small size, and are characterised either by short horns, as in the *Bos longifrons*, or by the entire absence of these weapons."

The following fossil species have been also named:—*Bos trochocerus* (Hermann von Meyer), sub-Apennine beds; Buffle Fossile de Sibérie (Cuv.); *Bos* (*Bison ?*) *bombifrons* (Harlan), Big-Bone-Lick, North America; *Bos Pallasii* (Dekay), *Bos moschatus fossilis* (?), *Bos canaliculatus* (?) (Fischer), Siberia and North America; *Bos velaunus* (Robert), Cussac, Haute Loire.

Abundant remains of the Ox were found by Captain Cautley in the Sewalik Mountains, at the southern foot of the Himalayas, between the Sutlej and the Ganges, partly lying on the slopes among the ruins of fallen cliffs, and partly in situ in the sandstone, in company with the bones of mastodon, elephant, rhinoceros, hippopotamus, hog, horse (comparatively scarce), elk, deer (several varieties); *Carnivora*, canine and feline (comparatively scarce); crocodile, gavial, *Emys*, *Trionyx*, and fishes. There were also portions of undescribed *Mammalia*.

BOVISTA, a genus of plants belonging to the natural order *Fungi*. This name was given it by Dillenius, and is a Latinised version of Bofist, its German name. In many parts of England its common name is Bullfice, and some writers call it Bull Puff-Ball. The genus Bovista was at one time included under *Lycoperdon* [LYCOPERDON], and the type of the genus, *Bovista gigantea*, was called by Linnæus *Lycoperdon Bovista*. The present *Lycoperdon Bovista* is the common or Wolf Puff-Ball. The difference between the genera is, that *Lycoperdon* has a single peridium, while *Bovista* has a double one.

The *Bovista gigantea*, Bull Puff-Ball, Frog's Cheese, and Bullfice, is interesting on account of the enormous size it attains. It has the form of a flattened ball, at first of a perfectly white colour. Specimens have been gathered measuring as much as 9 feet in circumference. When they have attained their full size, they begin to change colour; the external peridium cracks and peels off, the inner one also bursts at the apex. The interior is composed of a mass of tissue, which when young is white and moist, but at length becomes coloured and dry, and on being pressed emits a large quantity of powdery matter, which on being examined is found to consist entirely of sporules. On examining the mass inside it is found to consist of filaments which are mixed with sporules. Burnett says, "It is probably the smoke that arises from these fungi when burned, or some of their allies, the Lycoperdons, which forms the secret method advantageously employed by some persons who keep bees, in order to stupify the insects without killing them, while their hives are being robbed of all their honey." Gerarde says, "The common people use this fungus to kill or smoulder their bees." This practice has recently led to a curious discovery. Mr. H. B. W. Richardson, a surgeon, living at Mortlake, struck with the fact of its stupifying bees, was induced to try its effects upon other animals. Cats and dogs having been submitted to the action of smoke from the burning fungus, they were found to be narcotised in the same manner as if under the influence of ether or chloroform. A dog with a large tumour of the abdomen was narcotised, and whilst under its influence the tumour was removed, the animal giving no sign of pain. The narcotic principle seems to be formed during the process of combustion. Mr. Richardson found that it was capable of producing the death of animals. At present no advantage seems to be gained by administering this vapour instead of ether or chloroform; at the same time, it is an interesting fact in the history of the properties of plants. It is curious that this fungus is stated by Dr. Badham to be amongst those which are eatable. He says however that "no fungus requires to be eaten so soon after gathering as this," and adds, in a note, that he has been informed that it is sometimes served on state occasions at the Freemasons' Tavern. The best way of cooking it is "to cut it into slices, and fry these in egg and bread crumbs." In Mr. Richardson's experiments the dried fungus was employed. An Italian species, the *B. furfuracea*, which grows in great abundance on the heaths near Florence, is collected and sold in the markets, and, according to Micheli, is an esteemed article of food.

(Bischoff, *Medicinisch-Pharmaceutische Botanik;* Burnett, *Outlines of Botany; Association Medical Journal*, No. xxii.)

BOWERBANKIA, a genus of Ascidioid Polypes, or *Polyzoa*, belonging to the family *Vesiculariadæ*. It was named by Dr. Farre in honour of Mr. J. S. Bowerbank. The following character is given by Dr. Johnston in his 'British Zoophytes:'—Polypidom confervoid, matted or irregularly branched; the cells sessile, unilateral, irregular; the inflected portion with a spinous or filamentous rim. The polypes ascidian, with ten ciliated tentacula, and a strong gizzard. There is but one British species, *B. imbricata*. It has ovate or ovato-cylindrical cells, which are irregularly scattered on the polypidom in dense clusters. In its young state the polypidom is creeping and matted; but as it arrives at maturity it becomes arbuscular and erect. From this circumstance several names have been given to this species. It is found growing on the *Fuci* and corallines which are exposed at low water, and very generally distributed on the British coast. It grows in profusion on the chains of the steam-ferries at Southampton and Portsmouth. (Johnston, *British Zoophytes*.)

BOWSTRING-HEMP. [SANSEVIERA.]

BRACHE'LYTRA, a division of the order *Coleoptera*. The insects of this section (which answers to Linnæus's genus *Staphylinus*) may be distinguished by the elongate form of the body and the shortness of the wing-cases, which in most instances scarcely cover one-third of the length of the abdomen: their maxillæ are furnished with only one palpus. The apex of the abdomen is provided with two vesicles, which can be protruded at the will of the animal.

The habits of the *Brachelytra* are very various, but the greater number of the species are found in putrid animal or vegetable substances, upon which they feed; some are carnivorous. The shortness of the wing-cases probably allows of a greater flexibility in the body.

BRA'CHINUS, a genus of Insects belonging to the order *Coleoptera* and the section *Truncatipennes*. Generic characters:—Body oblong; head and thorax comparatively narrow, the latter generally somewhat of a truncated heart-shape; palpi and antennæ rather thick, the terminal joint of the former is slightly thicker than the basal joints, and has its apex truncated; mentum emarginate, and furnished with a small tooth-like process in the middle.

The *Brachini* possess a remarkable power of violently expelling from the anus a pungent acrid fluid, which, if the species be large, has the power of producing a discoloration of the skin similar to that caused by nitric acid. A loud report, considering the size of the insect, accompanies the expulsion of this fluid, which being discharged instantly evaporates.

About five species of the genus *Brachinus* have been found in this country, of which *B. crepitans* is the most common. It is found under stones, and occurs plentifully in chalky districts. This species is rather less than half an inch long; the head, thorax, and legs are of a yellowish-red colour; the wing-cases are greenish, or blue-black; the antennæ are reddish, with the third and fourth joints black. Many of the species of *Brachinus* resemble the above in colour. The species of the genus *Aptinus* (a genus very closely allied and differing chiefly in being apterous) are generally of a yellow colour, having four black spots on the elytra; the head and thorax are also often more or less suffused with black; they are likewise of a larger size for the most part, and abound more particularly in warm climates.

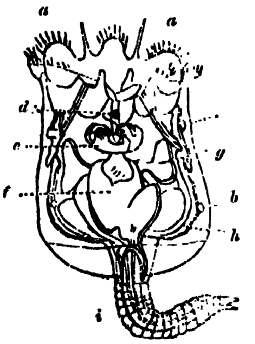
BRACHIOBDELLA. [ANNELIDA.]

BRACHIONÆA, a family of animals belonging to the order *Rotifera*. It embraces a large number of species formerly included under the genus *Brachionus*. It is distinguished from other families of *Rotifera* by the possession of two rotatory organs, and a lorica or shell. The wheels, or rotatory organs, are apparently composed of five parts, three of which are central, and two lateral; the latter of which alone form the true rotatory organs, the others being only ciliated frontal portions. Some have two setæ proceeding from the rotatory apparatus, as in *Synchæta*. The jaws are supplied with teeth and four muscles. They are supplied with biliary glands and ovary, male organs, and a contractile vesicle. Ehrenberg regards a red spot in them as indicative of the presence of a nervous system.

This family comprises the following genera:—*Pterodina, Anourella, Brachionus, Lepadella, Euchlanis, Dinocharis, Salpina, Colmella, Rutulus, Polyarthra.*

Ehrenberg makes seventeen genera; but Dujardin has reduced the number to ten, on account of the insignificant characters on which Ehrenberg's genera are founded.

Brachionus may be taken as a type of the family, and *B. urceolaris* is one of its most characteristic species. The genus *Brachionus* has a single eye (*d*), and a furcate foot or tail (*i*). It has a reddish colour, the shield smooth, with six short spines in front; the posterior extremity rounded. The jaws have each five teeth. Both male and female organs are present. It is a very common species in both brackish and fresh waters. Dujardin says he has constantly found it in the cisterns of the Jardin des Plantes, in Paris, and especially in that in which the aquatic plants grow. A few years ago the waters of the Serpentine, in Hyde Park, swarmed with this species, and it is very constantly present in the waters supplied to the cisterns of London for drinking purposes.



Brachionus urceolaris, highly magnified.

BRACHIONUS. [BRACHIONÆA.]

BRACHIO'PODA, or *Brachiopodous Mollusca*, Cuvier's fifth class of Mollusks, the Palliobranchians (*Palliobranchiata* of De Blainville), being the first order of De Blainville's third class of Mollusks (*Acephalophora*).

This class, though comparatively low in the scale of creation, is interesting to the physiologist, and of considerable value to the geologist, who finds in the fossil forms no small portion of those natural medals which indicate the history of the stratification of our globe. Comparatively few of the species exist in the seas of the present day, but in former periods of the earth's surface they occupied the position now taken by the Lamellibranchiate *Mollusca*.

Cuvier, in his anatomy of *Lingula anatina*, in the 'Annales du Muséum,' first made known that organisation by which the mantle, in addition to its office of secreting the shelly defence of these bivalves, is made subservient to the circulating system. Instead of the branchiæ of the ordinary bivalves he found in the situation usually occupied by them two fringed and spirally-disposed arms, and that the branchiæ presented themselves on the internal surface of both lobes of the mantle in oblique parallel lines. He further found that these lobes were traversed by vessels of considerable size, which returned the blood from the organs of respiration, and that these branchial veins terminated in two symmetrical systemic hearts. Here was a new type of circulation, and to the mollusks which presented these interesting and important modifications he gave the name at the head of our article, significative of the fringed arms which in this class took the place of the foot or organ of progression in the cockle, &c.

Lamanon and Walsh had previously taken the analogous parts of *Terebratula* for branchiæ, and Pallas, who is not quoted by Cuvier, describes the arms of *Terebratula* with minuteness and accuracy, but considers them as branchiæ, and compares them to those of a fish.

De Blainville, in the 'Dictionnaire des Sciences Naturelles,' gives an account of the organisation of *Terebratula*. But both Cuvier and De Blainville were led into error in their attempts to trace out some parts of the organisation of *Terebratula;* and it was reserved for Mr. Owen, in his acute, accurate, and interesting paper 'On the Anatomy of the *Brachiopoda* of Cuvier, and more especially of the Genera *Terebratula* and *Orbicula*,' published in the 'Transactions of the Zoological Society of London' (vol. i. p. 145), and derived from the dissection of specimens brought to this country by Mr. Cuming and Captain James Ross, R.N., fully to investigate the subject so as to leave little or nothing to be desired upon the subject of the anatomy of *Lingula* and of the two genera last named. Our limits will not permit us to follow the learned author through his memoir, the whole of which, together with the beautiful illustrations that accompany it, is worthy of the most attentive perusal by the physiologist and zoologist. The following general remarks from Professor Owen's paper illustrate his views. It should be premised that the *Brachiopoda* are cryptandrous.

"On comparing together," says Mr. Owen, "the three genera of *Brachiopoda* above described, we find that although *Orbicula*, in the muscular structure of its arms and the proportion of the shell occupied by its viscera, is intermediate to *Lingula* and *Terebratula*, yet that in the structure of its respiratory organs, its simple alimentary canal, and its mode of attachment to foreign bodies, it has a greater affinity to the latter genus. The modifications that can be traced in the organisation of these genera have an evident reference to the different situations which they occupy in the watery element. *Lingula*, living more commonly near the surface, and sometimes where it would be left exposed by the retreating tide, were it not buried in the sand of the shore, must meet with a greater variety and abundance of animal nutriment than can be found in those abysses in which *Terebratula* is destined to reside. Hence its powers of prehension are greater, and Cuvier suspects it may enjoy a species of locomotion from the superior length of its pedicle. The organisation of its mouth and stomach indicates however that it is confined to food of a minute description; but its convoluted intestine shows a capacity for extracting a quantity of nutriment proportioned to its superior activity and the extent of its soft parts. A more complex and obvious respiratory apparatus was therefore indispensable, and it is not surprising that the earlier observers failed to detect a corresponding organisation in genera destined to a more limited sphere of action. The respiration indeed as well as the nutrition of animals living beneath a pressure of from 60 to 90 fathoms of sea water, are subjects of peculiar interest, and prepare the mind to contemplate with less surprise the wonderful complexity exhibited in the minutest parts of these diminutive creatures. In the stillness pervading these abysses they can only maintain existence by exciting a perpetual current around them in order to dissipate the water already loaded with their effete particles, and bring within the reach of their prehensile organs the animalcula adapted for their support. The actions of *Terebratula* and *Orbicula*, from the firm attachment of their shells to foreign substances, are thus confined to the movements of their brachial and branchial filaments, and to a slight divarication or sliding motion of their protecting valves; and the simplicity of their digestive apparatus, the corresponding simplicity of their branchiæ, and the diminished proportion of their soft to their hard parts, are in harmony with such limited powers. The soft parts in both genera are however remarkable for the strong and unyielding manner in which they are connected together. The muscular parts are in great proportion and of singular complexity, as compared with ordinary bivalves; and the tendinous and aponeurotic parts are remarkable for the similarity of their texture and appearance to those of the highest classes. By means of all this strength they are enabled to perform the requisite motions of the valves at the depths in which they are met with. *Terebratula*, which is more remarkable for its habitat, has an internal skeleton superadded to its outward defence, by means of which additional support is afforded to the shell, a stronger defence to the viscera, and a more fixed point of attachment to the brachial cirri.

"The spiral disposition of the arms is common to the whole of the brachiopodous genera whose organisation has hitherto been examined; and it is therefore probable that in that remarkable genus *Spirifer*, the entire brachia were similarly disposed, and that the internal calcareous spiral appendages were their supports. If, indeed, the brachia of *Terebratula psittacea* had been so obtained, this species would have presented in a fossil state an internal structure very similar to that of *Spirifer*.

"In considering the affinities of the *Brachiopoda* to the other orders of *Mollusca*, I shall compare them, in the first place, with the Lamellibranchiate Bivalves, to which they present the most obvious relations in the nature and forms of their organs of defence. To these they are in some respects superior. The labial arms are more complex prehensile organs than the corresponding vascular laminæ on either side of the mouth of the *Lamellibranchiata*. The whole muscular system is more complex; and the opening as well as the closing of the shell being regulated by muscular action, indicates a higher degree of organisation than where the antagonising power results from a property of the cardinal ligament, which is independent of vitality, viz. elasticity. With respect however to the respiratory organs, the modifications which these have presented in *Orbicula* and *Terebratula* show the Brachiopods to be still more inferior to the *Lamellibranchiata* than was to be inferred from the structure of the branchiæ in *Lingula*; and notwithstanding the division of the systemic heart, I consider that there is also an inferiority in the vascular system. Each heart, for example, in the *Brachiopoda* is as simple as in *Ascidia*, consisting of a single elongated cavity, and not composed of a distinct auricle and ventricle, as in the ordinary bivalves; for in these, even when, as in the genus *Arca*, the ventricles are double, the auricles are also distinctly two in number; and in the other genera, where the ventricle is single, it is mostly supplied by a double auricle. The two hearts of the *Brachiopoda*, which in structure resemble the two auricles in the above bivalves, form therefore a complexity or superiority of organisation more apparent than real. Having been thus led to consider the circulating as well as respiratory systems as constructed on an inferior plan to that which pervades the same important systems in the Lamellibranchiate Bivalves, I infer that the position of the *Brachiopoda* in the natural system is inferior to that order of *Acephala*.

"Among the relations of the *Brachiopoda* to the Tunicated *Acephala*, and more especially to the *Ascidiæ*, we may first notice an almost similar position of the extended respiratory membranes in relation to the mouth, so that the currents containing the nutrient molecules must first traverse the vascular surface of that membrane before reaching the mouth; the simple condition, also, to which the branchiæ are reduced in *Orbicula* and *Terebratula* indicates their close affinity to the *Ascidiæ*. But in consequence of the form of the respiratory membranes in the *Brachiopoda*, which is so opposite to that of the sacciform branchiæ of the *Ascidiæ*, the digestive system derives no assistance from that part as a receptacle for the food, and the superaddition of prehensile organs about the mouth became a necessary consequence. The Brachiopods again are stationary, like the *Ascidiæ*, and resemble the *Boltenia* in the pedunculated mode of their attachment to foreign bodies.

"With the *Cirripeda* their relation is one of very remote analogy, their generative, nervous, and respiratory organs being constructed on a different type, and their brachia manifesting no trace of their articulate structure. In all essential points the *Brachiopoda* closely correspond with the Acephalous *Mollusca*, and we consider them as being intermediate to the Lamellibranchiate and Tunicate orders; not however possessing, so far as they are at present known, a distinctive character of sufficient importance to justify their being regarded as a distinct class of Mollusks, but forming a separate group of equal value with the *Lamellibranchiata*."

The structure of the shells of the *Brachiopoda* has been attentively studied by Dr. Carpenter, and the results of his investigations have been published in his 'Report on the Microscopic Structure of Shells,' made to the British Association.

The following is De Blainville's arrangement of the *Brachiopoda*, slightly modified:—

Shell Symmetrical.

Terebratula (Bruguières). Animal depressed, circular or oval, more or less elongated. Shell delicate, equilateral, subtriangular, inequivalve, one of the valves larger and more rounded (bombée) than the other, prolonged backwards into a sort of heel, which is sometimes recurved into a kind of hook-like process, and pierced at its extremity by a round hole, but more frequently divided into a fissure more or less large and of variable form. The opposite valve generally smaller, flatter, and sometimes operculiform. Of that complicated loop or internal support to which the arms are attached we shall presently speak at large. Hinge on the border, condyloid, placed on a straight line, and formed by the two oblique articulating surfaces of the one valve placed between the corresponding projections of the other. A sort of tendinous ligament comes forth from the hole or fissure above described, by which the animal fixes itself to submarine bodies.

The following is Mr. Owen's description of the peculiar, complex, and extremely delicate testaceous apparatus, sometimes called 'the carriage-spring' by collectors, attached to the internal surface of the imperforate valve:—

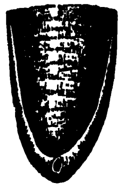
"The principal part of this internal skeleton, as it may be termed, consists of a slender, flattened, calcareous loop, the extremities of which are attached to the lateral elevated ridges of the hinge; the crura of the loop diverge, but again approximate to each other as they advance for a greater or less distance towards the opposite margin of the valve; the loop then suddenly turns towards the perforate valve, and is bent back upon itself for a greater or less extent in different species. When the loop is very short and narrow, as in *T. vitrea*, Brug., there is but a small tendency towards a reflected portion; but where the loop is of great length and width, as in *T. Chilensis*, Brod., *T. dorsata*, Lam., and *T. Sowerbii*, King., the reflected portion is considerable. The loop, besides being fixed by its origins or crura, is commonly attached to two processes going off at right angles from the sides, or formed by a bifurcation of the extremity, of a central process, which is continued forwards to a greater or less extent from the hinge; but it is sometimes entirely free, except at its origins, as, for example, in *T. vitrea*. This reflected loop, forming two arches on either side the mesial plane, towards which their concavities are directed, I have figured as it exists in *T. Chilensis* and *T. Sowerbii*. It is represented of a similarly perfect form in *T. dentata*, by M. De Blainville in his 'Malacologie;' and the same apparatus in *T. dorsata* is very well figured by Chemnitz, by Sowerby, and more recently by G. Fischer de Waldheim. A similar form is also figured in another species of *Terebratula* by Poli.

"The arches of the loop are so slender that, notwithstanding their calcareous nature, they possess a slight degree of elasticity and yield a little to pressure; but for the same reason they readily break if the experiment be not made with due caution. The interspace between the two folds of the calcareous loop is filled up by a strong but extensile membrane, which binds them together, and forms a protecting wall to the viscera: the space between the bifurcated process in *T. Chilensis* is also similarly occupied by a strong aponeurosis. In this species the muscular stem of each arm is attached to the outer sides of the loop and the intervening membrane. They commence at the pointed processes at the origins of the loop, advance along the lower portion, turn round upon the upper one, and are continued along it till they reach the transverse connecting bar, where they advance again forwards, and terminate by making a half-spiral twist in front of the mouth. It is these free extremities which form the third arm mentioned by Cuvier. These arms are ciliate on their outer side for their entire length, but the cilia are longer and much finer than the brachial fringes of *Lingula*; and except at the extreme ends, which have a slight incurvation, they are uniformly straight. There is thus an important difference between *Lingula* and those species of *Terebratula* which resemble *T. Chilensis* in the powers of motion with which the arms are endowed; since, from their attachment to the calcareous loop, they are fixed, and cannot be unfolded outwards as in *Lingula*. Owing to this mode of connection, and their ciliated structure, their true nature was much more liable to be mistaken by the early observers, though it appears not to have escaped the discrimination of Linnæus, who, as Cuvier has observed, founded his character of the animal of *Anomia* on the organisation of one of the *Tereblatulæ* which he included in that genus."

The recent species are numerous and widely diffused, and the genus appears to be capable of flourishing in extremely warm and extremely cold regions, as well as in more temperate climates. Thus some of the species have been found in the Indian seas and at Java (*T. flavescens*, Lam., for example), and *T. psittacea*, brought home from the late expedition by Captain James Ross, R.N., was fished up from a depth of twenty-two fathoms near Felix Harbour, in lat. 70° N., on the east side of Boothia. The average depth at which *Terebratula* has been found ranges from ten to ninety fathoms. De Blainville has thus subdivided the species :—

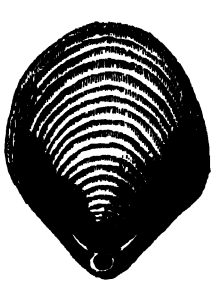
A. Summit of the larger valve pierced with a round hole, well defined.

1. Valves triangular, with a straight anterior border.
Example, *Terebratula digona* (fossil).



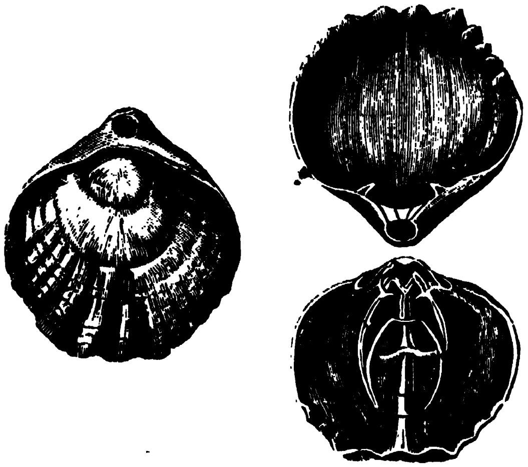
Terebratula digona.

2. Valves rounded at their anterior border.
Example, *Terebratula globosa* (recent).



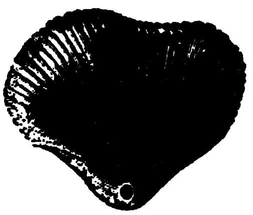
Terebratula globosa.

3. Valves raised as it were, or hollowed on the mesial line.
Examples, *Terebratula sanguinea*, and *Terebratula dorsata* (recent).



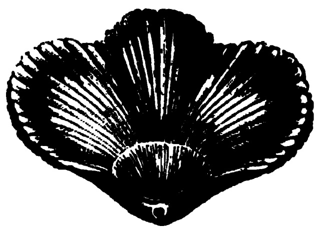
Terebratula dorsata. Internal views.

Bilobated, the valves striated from the summit to the circumference, and deformed as it were at the junction of their border.
Example, *Terebratula deformis* (fossil).



Terebratula deformis.

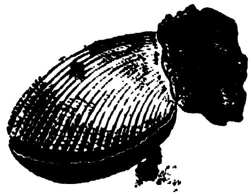
5. Trilobated as it were by the projection of the mesial part.
Example, *Terebratula alata* (fossil).



Terebratula alata.

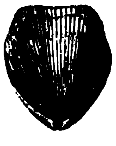
B. The heel of the larger valve deeply notched up to the border of articulation; notch or fissure rounded.

1. Valves rounded at their anterior border.
Example, *Terebratula rubra* (recent).



Terebratula rubra.

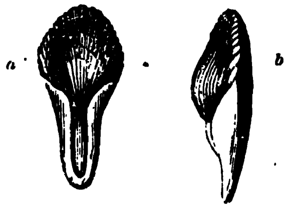
2. Valves sub-bilobated by the depression or emargination, which is apparent at the anterior border.
Example, *Terebratula Caput Serpentis* (recent).



Terebratula Caput Serpentis.

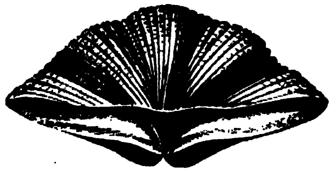
C. The opening of the heel of the larger valve, marginal, triangular, and elongated.

1. Valves rounded.
Example, *Terebratula Lyra* (fossil).



Terebratula Lyra. *a*, Front view; *b*, side view.

2. The valves sub-bilobated.
Example, *Terebratula canalifera* (fossil).

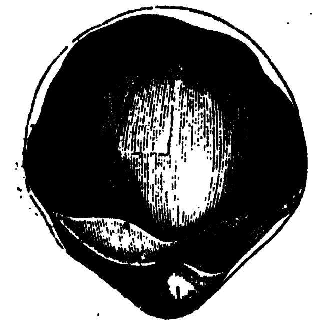


Terebratula canalifera.

3. The valves rounded; a mesial partition (*cloison*) in the larger valve, placed between two in the smaller, so as to give in the cast the representation of five distinct pieces, three for one valve and two for the other.
Genus *Pentastera*, Sowerby.—Fossil.

D. Opening of the heel marginal, triangular, but much larger transversely than longitudinally. Line of articulation quite straight.

1. The small valve provided in its mesial portion with a straight flattened support, bifurcated at its free extremity; a partition (*cloison*) in the other valve penetrating into this bifurcation.
Genus *Strygocephalus*, Defrance.—Fossil.
Example, *Strygocephalus Burtini.*

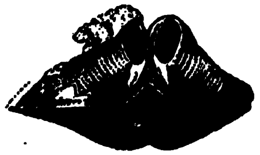


Strygocephalus Burtini.

2. The lateral parts of the support formed of a very fine spiral filament, so as to produce two hollow somewhat conical masses which nearly fill the whole of the shell.

Genus *Spirifer*, Sowerby.

Example, *Spirifer trigonalis* (fossil).



Internal view of *Spirifer trigonalis*, showing the spiral processes.

E. The upper valve operculiform or very flat, system of support beginning to disappear.

1. Upper valve very flat.

Genus *Magas*, Sowerby.—Fossil.

Example, *Magas pumilus*.

Magas pumilus.

2. Upper valve very much excavated above, summit of the lower valve not pierced, and divided into two nearly equal parts by a well-developed mesial furrow.

Genus *Producta*, Sowerby.—Fossil. (See 'Min. Con.,' pl. 320.)

Example, *Producta Martini*.

Producta Martini.

The fossil *Terebratulæ* (properly so called) are extremely numerous, and assist in the identification of strata from the supracretaceous group to some of the lowest formations in the grauwacke series, both inclusive.

As neither *Pentastera*, *Strygocephalus*, *Spirifer*, *Magas*, nor *Producta* has living representatives, they are placed here from the structure of their shells, which, judging from analogy, would indicate a brachiopodous construction allied to *Terebratula*. Indeed De Blainville retains that name throughout; but we think the differences of conformation warrant the separation of the fossils above distinguished, as subgenera of the *Terebratulinæ*. They occur principally in the more ancient fossiliferous beds.

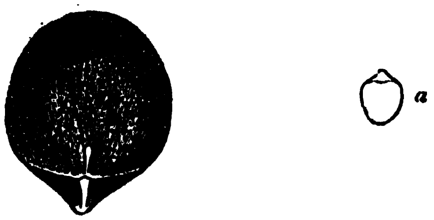
Thecidea, Defrance (*Thecidium*, Sowerby). De Blainville thus describes the genus:—"Animal entirely unknown, but very probably differing but little from that of *Orbicula*. Shell equilateral, regular, very inequivalve, and sufficiently similar to the *Terebratulæ* of the latter sections; one valve hollowed, the heel or hook recurved, entire, without a fissure and adhering; the other flat, operculiform, and without any trace of the internal support.

Hinge longitudinal; articulation by two distant condyles, as in the *Terebratulæ*, with a large mesial tooth in the flat valve fitting between the condyloid teeth of the concave valve.

Example, *Thecidium radiatum*.

The recent species above mentioned is an inhabitant of the Mediterranean, and found among the common red coral of the Tuscan seas.

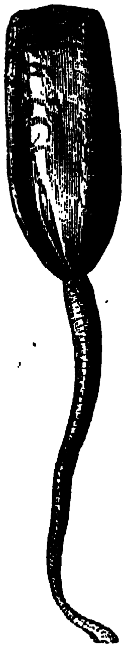
The fossil species are tolerably numerous, and Sowerby says that those which he had seen appeared to belong to the chalk, and were brought from Maastricht, and from Orglandes in Normandy.



Thecidium radiatum, viewed from above. *a*, nat. size.

Lingula (Brugières). Shell subequivalve, equilateral, depressed, a little elongated, truncated anteriorly; the summit mesial and posterior, with no trace of a ligament, but joined at the extremity to a long fibro-gelatinous peduncle, which is supposed to fix it vertically to submarine bodies; but in the specimen of *Lingula Audebardii* examined by Mr. Owen, there was no trace of the adhesion of any foreign body to the end of this peduncle. Muscular impressions multiple.

Example, *Lingula anatina*.



Lingula anatina.

The recent species have been found at depths ranging from the surface to seventeen fathoms; and specimens have been taken in hard coarse sand from four to six inches below the surface of the sand.

Lingula has been found in a fossil state in the Inferior Oolite of Yorkshire, in the Old Red-Sandstone formation, and in other old fossiliferous beds.

Strophomena, Rafinesque (fossil). Shell regular, equilateral, subequivalve; one valve flat, the other slightly excavated: articulation straight, transverse, with a small projection notched or dentelated transversely. No trace of an internal support.

Example, *Strophomena rugosa*.

Strophomena rugosa. View of lower side.

As *Strophomena* has no living representatives, at least none yet discovered, there can be no description of the animal, which is, however, judging from the construction of the shell, most probably brachiopodous.

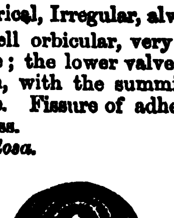
The fossil genera *Plagiostoma*, *Dianchora*, and *Podopsis* are placed by De Blainville under this section. [PLAGIOSTOMA; DIANCHORA; PODOPSIS.] We do not however think that there is such pregnant evidence of a true and entire brachiopodous organisation as to warrant this decided position under the Brachiopods. Indeed De Blainville himself says that some of the *Plagiostomata* are of the family *Terebratulæ*, and that the others (he instances *Plagiostoma Mantellii*) are entirely different, and he allows that these last ought to form a distinct genus of the family of Subostraccans. Defrance places *Podopsis* among the oysters.

* *

Shell Unsymmetrical, Irregular, always Adherent.

Orbicula (Lamarck). Shell orbicular, very much compressed; inequilateral, very inequivalve; the lower valve very delicate, adhering; the upper valve patelliform, with the summit more or less inclined towards the posterior side. Fissure of adhesion in the lower valve subcentral. Hinge toothless.

Example, *Orbicula lamellosa.*



Orbicula lamellosa. A single specimen, showing the cilia.

The recent species are found attached to stones, shells, sunken wrecks, &c., and have been found at depths ranging from not far below the surface to seventeen fathoms.

Fossil species are said to have been found in the Lower Greensand of Sussex, in the Speeton Clay of Yorkshire, in both the great and the inferior Oolite, in the carboniferous limestone, and in the Ludlow Rock below the Old Red-Sandstone.

G. B. Sowerby has satisfactorily proved that Lamarck's genus *Discina* must be expunged, it having been formed from specimens of *Orbicula Norvegica*, sent by Sowerby to Lamarck.

Crania (Retzius and others). G. B. Sowerby, who has done so much in the thirteenth volume of the 'Linnæan Transactions' to unravel the confusion which had previously been created by authors, gives the following generic characters:—

Shell inequivalve, generally equilateral, rather irregular, orbicularly subquadrate, and flattish; the upper valve patelliform, having its umbo or vertex rather behind the centre; the lower valve attached by its outside, the greater part of it being generally extended over the substance to which it adheres; and in this respect it differs greatly from *Orbicula*, which is attached by means of a ligament which passes through a fissure in the centre of the lower valve. There are four muscular impressions in each valve; of those in the upper valve two are in the posterior margin and the other two nearer the centre, but not always very near to each other; of those in the lower valve two are nearly marginal and rather distant, but the other two are nearly central, and so close together that they appear to form but one: they in general have a small projection between them; and the whole of the muscular impressions in the lower valve are frequently lost by decomposition in the fossil species, so as to appear only three oblique perforations, as Lamarck has described them.

Example, *Crania personata.*

Crania personata. 1, external view; 2, 3, internal view.

The recent species (and this is the only one known) is found adhering to stones and shells at very great depths. It is stated in the 'Zoological Journal,' by the Rev. M. J. Berkeley, that a specimen of *Crania personata* was taken by Captain Vidal at the depth of 255 fathoms.

There are several fossil species, mostly from the Chalk.

The species of *Brachiopoda* in the British seas are not numerous. The following are given in Forbes and Hanley's 'History of British Mollusca:'—

Terebratula (*Hypothyris*) *psittacea.* Undoubtedly indigenous, but very rare.

Terebratula Caput Serpentis. It was first described as British by Dr. Fleming, and has recently been dredged up in considerable numbers in deep water on various parts of the coast.

Terebratula Cranium. But one specimen of this has been obtained, which is now in the possession of Dr. Fleming.

Terebratula (*Megathyris*) *cistellula.* This species, which for some time was only known as a Crag-Fossil, has been taken in the Isle of Skye and in the deep-water fishing-grounds of Zetland.

Crania anomala. This species has been taken several times on various parts of the British coast.

BRACHY'CERUS, a genus of Coleopterous Insects of the family *Curculionidæ* (included in the genus *Curculio* by Linnæus). Generic characters:—Rostrum short; antennæ inserted towards the apex of the rostrum, short, 9-jointed, the basal joint longest, the terminal joint forming a knob; tarsi with all the joints entire, and without pubescence beneath. The species of this genus are apterous, and generally very rough. They appear to be peculiar to the south of Europe and Africa, and live upon the ground.

BRACHYPHY'LLUM, a genus of fossil plants, supposed to belong to the *Coniferæ.* One species, *B. mammillare* of Brongniart, occurs in the carbonaceous beds of the Bath Oolite Formation on the Yorkshire coast.

BRACHYPODI'NÆ, Swainson's name for a sub-family of Birds belonging to the *Merulidæ*, containing the following genera, or rather sub-genera:—

Brachypus, Swainson, thus characterised by him:—Bill short; rictus (gape) bristled; feet small, weak; lateral toes equal; hinder toe as long as the tarsus. Type, *Brachypus dispar*, Sw. (*Turdus dispar*, Horsfield).

Chloropsis, Jardine and Selby. Bill more lengthened; the tip much hooked; the notch forming a small distinct tooth; rictus smooth; feet small; lateral toes unequal; the hinder toe rather shorter than the tarsus.

Iöra, Horsfield. Bill nearly as long as the head, lengthened, conic; rictus smooth; tarsi somewhat lengthened, the anterior scales divided; tail even. Type, *Iöra scapularis*, Horsfield.

Andropadus, Swainson. Bill short; the upper mandible serrated near the tip; neck with setaceous hairs. Type, L'Importan, Le Vaillant.

Hæmatornis, Swainson. Bill short; rictus bristled; lateral toes unequal; hinder toe shorter than the tarsus. Types:—1. *Chrysorrhoëus*, Le Vaillant. 2. *Turdus hæmarrhous* of authors. 3. *Turdus bimaculatus* of Horsfield. 4. *Erythrotis* of Swainson (*Lanius jocosus* of Linnæus).

Mr. Swainson does not seem to have been aware that the appellation *Brachypus* had previously been conferred by Fitzinger on a sub-genus of *Saurians*, belonging to the *Chalcides* of Daudin, and it should therefore be no longer used to distinguish a sub-genus of birds. The term at the head of this article, which Mr. Swainson has applied to the sub-family, might be changed with advantage; for it may be liable to create confusion when unexplained by contexts, and leave the reader in doubt whether a sub-family of birds or reptiles is intended.

BRACHYPO'DIUM, a genus of Grasses [GRAMINACEÆ] belonging to the tribe *Festucineæ* of that order. It has unequal many-flowered glumes; the outer palea rounded on the back, setigerous at the summit, lateral nerves slightly converging, not vanishing upwards; the inner palea fringed on the ribs with rigid setæ; the styles terminal. Two of the species, *B. sylvaticum* and *B. pinnatum*, are British. This genus is distinguished from *Triticum* (Wheat) by the unequal glumes alone. (Babington, *Manual of British Botany.*)

BRACHYPTE'RES (Short-Winged Birds), Cuvier's name for those birds generally known by the name of Divers. [DIVERS.]

BRACHY'PTERYX, a genus of Birds approaching to *Saxicola*, thus defined by Dr. Horsfield:—

Bill with the culmen carinated between the nostrils, the sides being flattened, and rounded towards the apex, with the sides convex; edges subinflected; wings very short and obtuse: tail moderate and rounded; feet elongated and weak; the tarsi slender; the toes very slender, and the claws very much compressed; hallux or hind toe comparatively large.

Brachypteryx montana, Horsfield. The species on which the genus is founded has the following characters:—Weight of the male five, and of the female six drachms. In the male, the head, neck, and breast have a dark indigo-blue tint, inclining to black, with a grayish reflection on the surface, variegated with lighter and darker shades; on the throat and the lower part of the neck this colour passes into gray; on the forehead it is more intense, inclining to black. Above the eyes is an oblong white spot. The back, the wings above the shoulders, the coverts of the tail, the vent, hypochondriæ, and thighs are deep chestnut-brown, with a ferruginous reflection. The wings underneath, and the tail at the extremity and underneath, are pure blackish-brown; the shafts of the quill- and tail-feathers are black and shining. The inner vanes of the quills and the tail-feathers generally have a very deep brown colour. The exterior vanes of the tail-feathers are slightly tinted with the ferruginous lustre of the upper parts. The lower parts of the breast and abdomen are whitish. The plumes on the posterior portion of the body are very thickly disposed; the vanes consist of long, delicate, silky, pendulous laminæ or filaments, forming a lax covering about the lower parts of the abdomen, the hypochondriæ, and the root of the tail. The irides have a dark hue. The bill is black, and the tarsi are deep brown. The tint of the claws is somewhat lighter.

In the female, the dark blue tint, which in the male covers the head and neck, extends over the body generally, and also marks the exterior vanes of the quills. The interior vanes of the latter and the tail-feathers are dark brown, inclining to black. The throat and neck underneath have a dark grayish tint. The abdomen is grayish-white. Over the eyes it has, like the male, a white spot, and the bill and tarsi also agree with that. The covering of the abdomen, vent, and thighs is likewise long, delicate, silky, and pendulous.

Dr. Horsfield met with this species in one situation only, at an elevation of about 7000 feet above the level of the sea. He thinks it probable that it may be found on all the peaks of Java, which are covered with thick forests, accommodated to its peculiar habits. The recurrence, he observes, of several quadrupeds and birds, at a certain elevation, is as regular in that island as that of many plants and insects. Although local in its residence, Dr. Horsfield found the bird very numerous on Mount Prahu, which, he says, in the luxuriance of its vegetation and gloomy thickets, is probably not surpassed in any portion of the globe. In his daily excursions he uniformly observed and occasionally surprised it in its short sallies among the openings of the forest. It was chiefly found on the lowest branches of trees or on the ground. As the shortness of its wings incapacitates it for elevated or distant flights, its motions are low, short, and made with great exertion. It lives in the thickest coverts, feeding on the larvæ of insects, worms, &c., and there it forms its nest on the ground. "It utters," says Dr. Horsfield, "almost without interruption, a varied song. Its common note is a quickly reiterated babbling, resembling that of the *Curruca garrula* of Brisson, and other birds of this family: it also has a protracted plaintive note, but it sometimes rises to higher and melodious warblings, which, in the general silence of these elevated regions, afford an inexpressible sensation of delight to the mind of the solitary traveller."

Mountaineer Warbler (*Brachypteryx montana*).
The upper figure represents the female; the lower, the male.

This bird is the Ketek of the Javanese and Mountaineer Warbler of Latham.

(Horsfield, *Zoological Researches in Java and the neighbouring Islands*, and *Transactions of the Linnæan Society*, vol. xiii.)

BRACHYPUS. [BRACHYPODINÆ; CHALCIDES.]

BRACHY'TELES, a genus of *Quadrumana*, separated from *Ateles* by Spix, on account (among other differences) of the very small development of the thumb. [ATELES.]

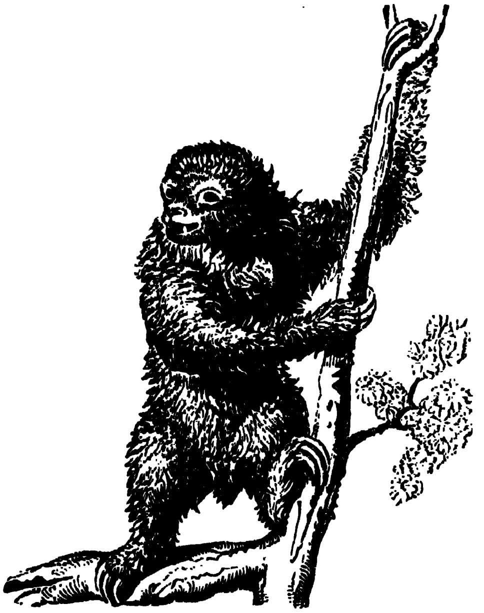
BRACKEN. [PTERIS.]

BRA'CON, a genus of Insects of the order *Hymenoptera* and family *Ichneumonidæ*. The insects of this genus are remarkable for the hiatus which there exists between the mandibles and the clypeus. The maxillæ are prolonged inferiorly; the second cubital cell of the wing is tolerably large and square; the ovipositor is long.

BRACT, the last leaf or set of leaves that intervenes between the true leaves and the calyx of a plant. When the time arrives for a plant to fructify, a change comes over its constitution, and parts are expanded, which, although under ordinary circumstances they would have become leaves, yet at this peculiar time are less developed, and appear in the form of scales or half-formed leaves. Of these the external are bracts, the next combine with each other and become calyx, the next assume the form of petals, and so on. Therefore whatever intervenes between the true leaves and the calyx is bract.

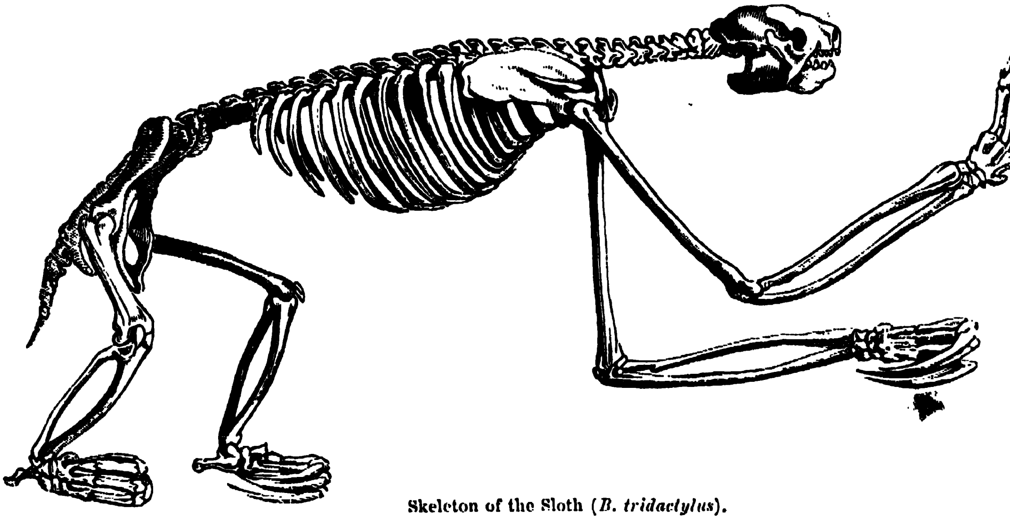
BRADYPUS, a genus of Mammals belonging to the order *Edentata* of Cuvier, and together with the genus *Unau*, or *Cholœpus*, composing a small family to which Cuvier gave the appellation of *Tardigrada*, from the peculiar conformation of their extremities, and the remarkable slowness of their pace. Both these genera were formerly included by Linnæus in the same group, under the common name of *Bradypus*, or Sloth; but later zoologists have separated them, on account of certain anomalies in their organic structure. It must however be confessed that the two genera of Sloths are closely approximated to one another in many essential details both of structure and economy; and this fact is the more remarkable and interesting since the modifications upon which their generic distinction has been founded are greater, and, as we might naturally presume, more influential, than those which frequently characterise two different families.

The order *Edentata* comprises a number of genera, perhaps the most singular and anomalous among Mammals, differing widely from all other quadrupeds, but unfortunately possessing so few natural affinities or relations of resemblance among themselves, that the order *Edentata* is sometimes regarded as the most arbitrary and artificial of all the primary groups into which Cuvier and Geoffroy have divided the *Mammalia*. The family *Tardigrada*, or Sloths, are more especially deserving of attention, as well from the singularity of their physical structure, and the mistakes which have hitherto prevailed among naturalists concerning the habits and manners of these singular animals, as on account of the relation which they present in their osteological details to the *Megatherium*, the most curious and anomalous of extinct animals. This family is distinguished from the other *Edentata* by a short round head, and the presence both of molar and canine teeth, the incisors alone being deficient; but above all by the great length and singular structure of their arms, which, adapting them to a mode of progression altogether peculiar to themselves, and consequently disqualifying them for the exercise of that species of locomotion common to ordinary quadrupeds, have caused them to be considered as the most miserable and unfortunate of beings, imperfect monsters of creation, equally remarkable for their disgusting appearance and helpless condition.



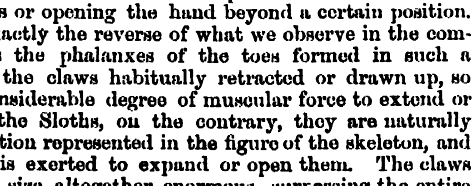
Sloth (*Bradypus tridactylus*).

To enable us clearly to comprehend the nature and functions of these animals, it will be necessary to enter into a short description of parts of their osteological structure. The view here given of the skeleton of the Sloth (*Bradypus tridactylus*) seems to indicate a distortion of certain parts and proportions altogether opposed to freedom of motion, at least of that kind of motion with which we are familiar in ordinary quadrupeds. The arm and fore-arm taken together are nearly twice as long as the leg and thigh, so that if the animal attempts to walk on all-fours it is obliged to trail itself painfully and slowly on its elbows, and if it stands upright on the hind legs the arms are so long that the fore fingers touch the ground. This disproportion between the anterior and posterior extremities, obviously deprives these animals of the power of moving on a plain surface with that speed which is so admirable in the generality of quadrupeds; and accordingly we are assured by all observers, that their mode of progression under these circumstances is of the most slow and painful nature. The Sloths however are not terrestrial animals, but live entirely among the thick branches of trees in the most extensive and solitary forests. This remarkable disproportion of their fore-arms is common to another genus of arboreal mammals, the real apes, in which, far from retarding their motions, this peculiar structure is of the most essential importance in adding to their agility. But the Sloths partake of none of the accessory advantages which the Apes possess. They have no opposeable thumb; their fingers are short, and so perfectly rigid that the joints ossify at a very early period of the animal's life, leaving them totally incapable of individual motion, whilst they are at the same time so completely enveloped in the common integuments of the hand that nothing is to be seen externally except the immense



Skeleton of the Sloth (*B. tridactylus*).

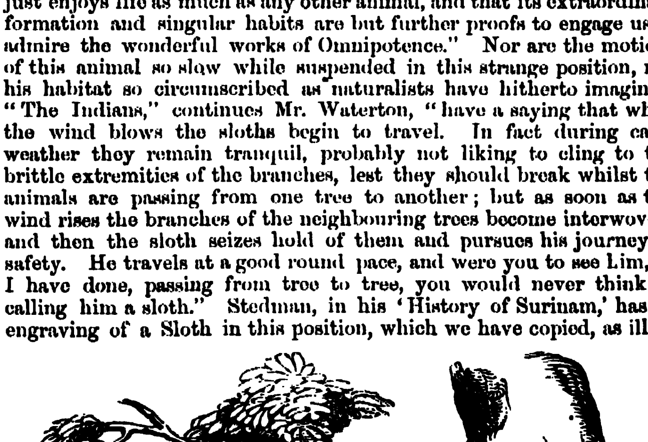
crooked claws with which they are provided. The wrist and ankle also are articulated or joined to the fore-arm and leg in an oblique direction; so that the palm or sole, instead of being directed downwards towards the surface of the ground, as in other animals, is turned inwards towards the body, in such a manner as to render it impossible for the Sloth to place the sole of its foot straight down upon a level surface, but to compel it, under such circumstances, to rest upon the external edge of the foot. This position is obviously but ill adapted for ease or facility of motion. But there is still another singularity in the structure of the foot of this animal which materially increases its difficulties of progression on a plain surface. This arises from the peculiar form of the last phalanx or joint of the fingers and toes, that, namely, which gives insertion to the claws, and which is articulated with the second phalanx in such a manner as to permit the fingers and claws to be strongly bent inwards along the palm and arm, but at the same time prevents the animal from raising them upwards or opening the hand beyond a certain position. This structure is exactly the reverse of what we observe in the common cat, which has the phalanxes of the toes formed in such a manner as to keep the claws habitually retracted or drawn up, so that it requires a considerable degree of muscular force to extend or depress them. In the Sloths, on the contrary, they are naturally depressed in the position represented in the figure of the skeleton, and the muscular force is exerted to expand or open them. The claws themselves are of a size altogether enormous, surpassing the entire foot in length. They are so sharp and crooked that they readily seize upon the smallest inequalities in the bark of the trees and branches among which the animals habitually reside; and, united to the great muscular strength and rigid formation of the extremities, furnish the most powerful weapons of defence. Nor are the form and articulation of the posterior extremities less singular than those of the anterior. The formation of the pelvis alone is of such a nature as to render it impossible for the Sloths to walk after the manner of ordinary quadrupeds; and the mode in which the hind legs are articulated with the pelvis, to use the expression of Baron Cuvier, seems almost expressly arranged for the purpose of depriving the animal of the use of its legs altogether. "If," says M. Cuvier, "we consider the Sloths in the relation which they bear to other animals, the general laws of organisation at present existing apply so little to their structure, the different parts of their body seem so completely contradictory of those laws of co-existence which we have found established in the rest of the animal kingdom, that we might be almost tempted to consider them as the remains of a former order of things, the living relics of that precedent nature of which we are obliged to seek the other ruins beneath the surface of the earth, and that they escaped by some miracle the catastrophe which destroyed their contemporary species."



Formation of the Pelvis.

If placed upon a plain surface, the Sloth moves with difficulty and only by seizing upon the little asperities which he finds in his way, and by that means dragging his body slowly forwards, just as we may observe a bat to do under similar circumstances. But this is a situation equally foreign to the habits and economy both of the Sloth and of the bat; and we are no more justified in judging of the nature of the one under these circumstances, than we should be in reasoning upon the habits of the other. The Sloth is eminently an arboreal quadruped: it is produced, it lives, and it dies in the trees; it very rarely voluntarily descends to the surface of the earth, and those therefore who observe it in that situation, have not a favourable opportunity of judging of its nature and functions.

We are indebted to the valuable observations of Mr. Waterton, during his 'Wanderings' in South America, for a final and satisfactory explanation of the apparent difficulties and inconsistencies in the structure and habits of the Sloth. "The sloth," says this traveller, "in its wild state, spends its whole life in the trees, and never leaves them but through force or accident; and what is more extraordinary, not upon the branches like the squirrel and monkey, but under them. He moves suspended from the branch, he rests suspended from the branch, and he sleeps suspended from the branch. Hence his seemingly bungled composition is at once accounted for; and in lieu of the sloth leading a painful life and entailing a melancholy existence upon its progeny, it is but fair to conclude that it just enjoys life as much as any other animal, and that its extraordinary formation and singular habits are but further proofs to engage us to admire the wonderful works of Omnipotence." Nor are the motions of this animal so slow while suspended in this strange position, nor his habitat so circumscribed as naturalists have hitherto imagined. "The Indians," continues Mr. Waterton, "have a saying that when the wind blows the sloths begin to travel. In fact during calm weather they remain tranquil, probably not liking to cling to the brittle extremities of the branches, lest they should break whilst the animals are passing from one tree to another; but as soon as the wind rises the branches of the neighbouring trees become interwoven, and then the sloth seizes hold of them and pursues his journey in safety. He travels at a good round pace, and were you to see him, as I have done, passing from tree to tree, you would never think of calling him a sloth." Stedman, in his 'History of Surinam,' has an engraving of a Sloth in this position, which we have copied, as illustrating its singular mode of progression. A specimen of *Cholæpus didactylus*, the Two-Toed Sloth, is now living in the Gardens of the Zoological Society, Regent's Park.



Mode of progression.

The conformation of the extremities is not the only part of its anatomy in which the Sloth differs from ordinary mammals. The number and form of the bones which compose the trunk, the nature of its teeth, and the conformation of its stomach and intestines, are all peculiar. The stomach is divided by transverse ligatures into four separate compartments, which bear a distant resemblance to the four stomachs of ruminating animals: they do not however exercise the functions of these organs, nor do the Sloths regurgitate their food, or subject it to a second process of mastication like the ox and the sheep. The intestines also are unusually short for an animal which lives entirely upon vegetable substances, scarcely equalling twice the length of the body, whilst those of ruminants frequently exceed ten times those dimensions. Their simplicity and diminutive size in the Sloths appear to be compensated by the superior and unusual complication of the stomach,—which, retaining the food for a longer period than in ordinary non-ruminating animals, allows it to be more perfectly macerated, and prepared for the action of the absorbent vessels which imbibe its nutritious particles in its passage through the intestines. The number of vertebræ in the necks of mammals is generally seven, so that the whales and dolphins, which have scarcely any neck at all, as well as the giraffe and camel, which have it developed in a most unusual degree, are all found to agree in this particular, however widely they differ in other respects: the *B. tridactylus* alone forms an exception to this otherwise universal rule, in having nine cervical vertebræ. What renders this circumstance still more surprising is, that the neck of the Sloth (*B. tridactylus*), notwithstanding its two supernumerary vertebræ, is far from long—being on the contrary much too short for its long fore legs if it were compelled to seek its food on the ground like other animals. But this defect is compensated, as well by the nature of the situation which it habitually occupies, suspended from the horizontal branches of the trees, as by its power of using the fore paw as a hand in conveying the food to its mouth, which, notwithstanding the rigidity of its members, it does with great address with one paw, whilst it clings firmly to the branches by means of the other three.

The dental system of the Sloths is the most simple that can well be conceived. They have no incisor teeth, but canines and molars only; and in the *B. tridactylus* the canines are diminutive, and in all respects very similar to the other teeth. The molar teeth are universally eight in the upper jaw and six in the lower, four and three on either side respectively. Their construction is most simple, consisting merely of a cylinder of bone, enveloped in enamel, and hollow at both ends,—at the upper by continual detrition, and at the under by default of ossification. They have no lamina of enamel penetrating the body of the tooth, as in other herbivorous animals, which renders them such effective instruments in grinding and masticating vegetable substances. Hence it results, that the mastication of the Sloth must be extremely imperfect, though the defect of dentition is probably compensated in some degree by the superior complication of the stomach.

The genera *Bradypus* and *Cholæpus*, together with the extinct fossil animals which have been called *Megatherium* and *Megalonyx*, and which, with the form and organisation of a sloth, nearly equalled the elephant in size, constitute the Cuvierian family *Tardigrada*. Besides the difference of the canine teeth, which are completely developed in *Cholæpus* and in *Bradypus*, of the same form and subject to the same detrition as the molars, these two genera are distinguished from one another by the number of toes on the fore-feet, which are three in the *Bradypus* and only two in the *Cholæpus;* by the comparative length of the fore-arms, which are much longer in the former than in the latter; by the number of cervical vertebræ in the *Bradypus*, as already mentioned; by the equally unusual number of ribs in *Cholæpus*, which amount to no fewer than forty-six, the greatest number hitherto found in any mammal, the species of *Bradypus* having but thirty-two; and by numerous other modifications which it is unnecessary to enumerate.

The Sloths are known to bring forth and suckle their young like ordinary quadrupeds. For this purpose they have two mammæ, which are situated on the breast; and the young Sloth, from the moment of its birth, adheres to the body of its parent till it acquires sufficient size and strength to shift for itself. The head of the Sloth or Ai (*B. tridactylus*) is short, the face small and round like that of the American monkeys, the ears concealed in the long hair which surrounds them, the eyes small and deeply sunk in the head, and the tail a mere rudiment. This species is found only in the most gloomy and retired tropical forests of South America. The Indians like its flesh, and are in continual pursuit of it.

In the list of specimens of *Mammalia* in the British Museum three species of *Bradypus* and one of *Cholæpus* are given. Several varieties have been described.

B. tridactylus, the Sloth or Ai. It has a short round head, furnished with coarse shaggy hair, disposed on the crown in verging rays, like that of the human species; the face is of a yellowish colour, covered with very short hair, whilst that of the body and extremities is universally long and shaggy; the eyes are encircled by a brown ring; the hair of the body varied with irregular patches of dark and light brown, or silvery white; between the shoulders there is an oval patch of short orange-coloured hair, of a finer quality than that found on other parts of the body, and divided in the centre by a longitudinal black stripe; the throat and breast are frequently of a light straw-colour. The texture of the hair is altogether peculiar, and more nearly resembles dry hay, or grass shrivelled and withered by the sun, than the hair of ordinary quadrupeds. It is coarse and flattened at the extremity, but as small at the root as the finest spider's web; and its dry and withered appearance forms the Ai's principal security against its pursuers, as it renders it extremely difficult to detect it whilst at rest among the branches covered with bark and moss of the same colour. It is only when in motion that it can be readily distinguished from the trunk beneath which it hangs suspended. In other respects different individuals of this species differ considerably from one another in the shades and disposition of their colours, and in the intensity of the mark between the shoulders; some even want this latter mark altogether, others are of a uniform ash-colour over the whole body, and there are others still which have the hair of the head parted in the centre, and hanging down on each side; but whether these constitute distinct species, or mere varieties of the common Ai, is a point hitherto undetermined: the cabinets of Europe do not afford sufficient materials for an extensive comparison, and no naturalist has ever examined the Ais with this view in their native regions.

B. torquatus, the Gipakeiou, is a very distinct species, even in the bony structure of its cranium. Its face is naked, and of a black colour; the hair of its body less flattened and withered-looking than in the common species; the forehead, temples, chin, throat, and breast covered with reddish or rust-coloured hair, slightly frizzled; on the crown of the head it is long and yellow, and on the rest of the body pale orange; but the most distinguishing mark of the species is a large black collar which completely surrounds the neck. Beneath this outer coat there is an inner one of very fine fur, which is of a dark brown colour on the collar, but gradually diminishes in intensity towards the croup, where it is entirely white.

Both these species feed upon the leaves of trees, and bring forth but a single young one at a birth. When in motion in the forests they emit a feeble plaintive cry, resembling the word 'Ai,' and which is the origin of the name they bear among the Europeans settled in America. They are extremely retentive of life, and have been seen to move their legs and exhibit other symptoms of vitality a full half-hour after being deprived of the heart and other viscera.

B. gularis, the Yellow-Faced Sloth, is supposed by some to be a variety of *B. tridactylus*.

BRAGANTIA, a genus of plants belonging to the natural order *Aristolochiaceæ*. One of the species, *B. tomentosa*, is said by Dr. Horsfield to be intensely bitter, and to be used as a medicine in Java.

BRAIN, a soft and pulpy organ, which in man occupies the cavity of the cranium, and forms one of the central masses of the nervous system. [NERVOUS SYSTEM.] In man and all the higher animals the nervous system consists of four distinct parts—the white threads called Nerves, knots or masses of nervous matter situated along the course of the nerves called Ganglions, a long cord of nervous matter filling the cavity of the vertebral or spinal column called the Spinal Cord, and a large mass of nervous matter now generally considered as a continuation and expansion of the spinal cord called the Brain. The Spinal Cord and Brain constitute the two central masses of the nervous system, that is, the immediate seat of the functions peculiar to this system.

The general mass of nervous matter designated under the common term Brain, together with its membranes, vessels, and nerves, completely fills the cavity of the skull. This mass is divided into three parts, the Cerebrum, or brain proper, which occupies the whole of the superior part of the cavity of the cranium; the Cerebellum, much smaller than the cerebrum, whence its name, Little Brain, which occupies the lower and back part of the cavity of the cranium; and the Medulla Oblongata, by much the smallest portion of the mass, situated at the basis of the cavity beneath the cerebrum and cerebellum. The medulla oblongata passes out of the cavity of the cranium into that of the vertebral canal by the foramen magnum of the occipital bone, being continuous with and forming the commencement of the spinal cord.

This general nervous mass is closely enveloped in three distinct membranous coverings, two of which have been called 'matres,' from the fanciful notion that they give rise to all the other membranes of the body. The external covering termed Dura Mater, from its being of a firmer texture than the other two membranes, incloses the brain with all its appendages, and lines the whole internal surface of the bones of the cranium. It is of a fibrous texture, the component fibres interlacing each other in every possible direction, and forming by their firmness and density the thickest and strongest membrane of the whole body. By its external surface the dura mater adheres everywhere to the inner surface of the cranium, just as the periosteum adheres to other bones. When torn from the cranium this surface appears somewhat rough and irregularly spotted with bloody points, which are the lacerated orifices of vessels that pass between the membrane and the surrounding bones. These vessels are much more numerous in the young than in the adult, and are most abundant at the sutures or junctions of the bones that compose the skull. The inner surface of the dura mater, which is shining and smooth, is lubricated and kept in a state of moisture by a fluid secreted by its own vessels. This membrane performs a twofold office; it supplies the place of the periosteum to the inner surface of the bones of the cranium, sustaining their nutrient vessels; and it serves as a defence to the brain, and a support to the different masses into which it is divided.

The dura mater gives off several elongations or productions called processes, which descend between certain portions of the brain; the most remarkable of which is termed the superior longitudinal process, which extends from the fore to the back part of the skull between the lateral halves of the cerebrum. Narrow in front, it becomes gradually broader as it passes backwards, bearing, as has been conceived, some resemblance in shape to a sickle or scythe, whence the common name of it, falx cerebri.

Where the falx cerebri terminates behind, there proceeds a large lateral expansion of the same membrane, extending across the back part of the skull beneath the posterior parts of the cerebrum, and forming a complete floor or vault over the cerebellum. This membranous expansion is called tentorium, the obvious use of which is to prevent the cerebrum from pressing upon the cerebellum; while from the middle of the tentorium proceeds another membranous expansion, which descends between the lobes of the cerebellum, and terminates insensibly at the edge of the foramen magnum, performing for the cerebellum the same office as the falx performs for the cerebrum: hence it is called falx cerebelli.

Moreover the component fibres of the dura mater in certain parts of its course separate into layers, which are so disposed as to leave spaces between them, for the most part of a triangular form. These triangular spaces, which are commonly termed sinuses, are lined by a smooth membrane perfectly analogous to that which lines the veins in the other parts of the body, and these sinuses perform the office of veins, returning the blood from all the parts of the brain to the neck. Nothing analogous to this structure occurs in any other part of the venous system. In almost every other part of the body the pressure of surrounding parts is a most important aid to these vessels in enabling them to carry on the circulation of the blood; but in the brain the venous tubes are guarded from pressure, the dense dura mater being for this purpose stretched so tensely over them that the weight of the surrounding parts is completely taken off them.

The smooth surface of the brain which is exposed on the reflection of the dura mater, is formed by its second investing membrane which is named the Tunica Arachnoidea, from the extreme tenderness and delicacy of its tissue, which gives it a resemblance to a spider's web. This thin colourless and transparent membrane is spread uniformly over the surface of the brain, covering all the eminences termed convolutions (*fig.* i. 2, 2), but not insinuating itself between any of the depressions between the convolutions. (*Fig.* iv. 7.) On account of its extreme tenuity and its close adhesion to the membrane beneath it, it cannot be easily separated from the latter; but there are situations at the basis where the arachnoid membrane, as it passes between opposite parts of the brain, can be seen distinct from the subjacent tunic.

The third investing membrane, the Pia Mater, derives its name like the former from the tenderness and delicacy of its tissue; but unlike the tunica arachnoidea, in which not a single blood-vessel has hitherto been described, the pia mater is exceedingly vascular. The blood-vessels with which every part of this delicate membrane is covered are the nutrient arteries of the brain; before they penetrate the brain these vessels divide, subdivide, and ramify to an extreme degree of minuteness upon the external surface of this membrane, so that the blood does not enter the tender cerebral substance with too great force. When a portion of the pia mater is gently raised from the brain, these blood-vessels appear as exceedingly fine delicate threads, which on account of the elasticity with which they are endowed are capable of elongation as they are drawn out of the cerebral substance. As the pia mater contains and supports the nutrient vessels of the brain, this membrane is not only spread as a general envelope over its entire surface, but it penetrates between all its convolutions, and lines every cavity which is formed in it.

It has been stated that the large portion of the cerebral mass, termed the cerebrum, occupies the whole of the upper part of the cavity of the cranium. The cerebrum is divided into two equal lateral halves termed hemispheres (*fig.* i. 2, 2), which have an ovoid figure somewhat resembling an egg cut longitudinally into two equal parts. The hemispheres are separated from each other by the membrane already described, the falx cerebri (*fig.* i. 3); and their inner sides in apposition with the falx are flattened, while their upper and outer surfaces are convex, being accurately adapted to the concavity formed by the inner surface of the bones of the cranium.

Each hemisphere is subdivided into an anterior, a middle, and a posterior lobe, but it is only on the under surface of the brain that these lobes are accurately defined. (*Fig.* ii. 1, 2, 3.) The anterior and middle lobes are separated from each other by a deep fissure named the fissura sylvia (*fig.* ii. 4), which extends obliquely backwards from the basis to a considerable depth between the convolutions; but the middle is distinguished from the posterior lobe, not by a fissure but by a superficial excavation on the under surface of the posterior lobe. (*Fig.* ii. 5.) The anterior lobes rest upon the orbital plates of the frontal bone; the middle lobes are lodged in the temporal fossæ formed by the sphenoid and temporal bones, while the posterior lobes are supported upon the tentorium.

The whole of the external convex surface of the hemispheres is divided into numerous eminences termed convolutions, which run in different directions, and are of different sizes and lengths in different parts of the hemisphere. (*Fig.* i. 2, 2.) The depressions or fissures between the convolutions, termed clefts, or sulci, generally penetrate the consistence of the brain to the depth of about an inch or an inch and a half. (*Fig.* iv. 7.) The greater number of these pursue a

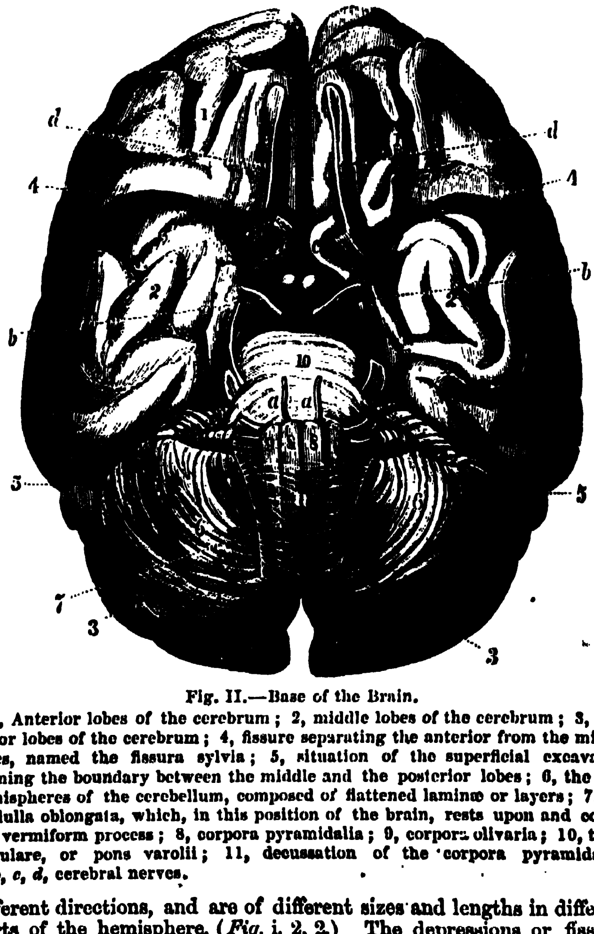

Fig. II.—Base of the Brain.

1, Anterior lobes of the cerebrum; 2, middle lobes of the cerebrum; 3, posterior lobes of the cerebrum; 4, fissure separating the anterior from the middle lobes, named the fissura sylvia; 5, situation of the superficial excavation forming the boundary between the middle and the posterior lobes; 6, the two hemispheres of the cerebellum, composed of flattened laminæ or layers; 7, the medulla oblongata, which, in this position of the brain, rests upon and covers the vermiform process; 8, corpora pyramidalia; 9, corpora olivaria; 10, tuber annulare, or pons varolii; 11, decussation of the corpora pyramidalia; *a*, *b*, *c*, *d*, cerebral nerves.

zigzag course, but some run longitudinally, others obliquely; some communicate with each other, while others terminate separately in the substance of the brain. (*Fig.* iv. 7.)

The nervous matter constituting the cerebrum is composed of two distinct substances, which differ from each other materially both in their colour and consistence. (*Fig.* iv. 7.) The outer substance is sometimes termed cineritious, from its being of a grayish-brown colour; at other times cortical, from its surrounding the inner part of the brain, as the bark the inner parts of the tree; by some it is also called glandular, and by others secretory, from the supposition that its nature is that of a gland, and that it secretes a peculiar fluid. It is of a softer consistence than the inner part, and leaves by desiccation a smaller quantity of solid residuum. It is composed almost entirely of blood-vessels connected and sustained by exceedingly fine cellular membrane. Its structure is uniform throughout, presenting no appearance whatever of a fibrous texture. It gives to the entire surface of the cerebrum an external covering, generally about the tenth of an inch in thickness. (*Fig.* iv. 7.)

The inner substance, termed white or medullary (*fig.* iv. 7), is firmer in consistence and larger in quantity than the gray matter; and when an incision is made into it, its surface is spotted with red points, the cut orifices of its vessels, which vary in number and size according as they may be more or less distended with blood. It is now universally agreed that this part of the brain is composed of fibres. When examined in its recent and most perfect state, especially after it has been artificially hardened and condensed by the action of heat or certain chemical substances, if it be carefully scraped with a blunt instrument these fibres become perfectly distinct and are of considerable magnitude, with furrows between them, which for the most part are placed in such a direction as to converge towards the base of the brain. (*Fig.* iv. 6, 5, 4.) The fibres do not merely unite, forming what are called commissures, but they actually cross each other and pass into the opposite sides of the body. This decussation of the medullary fibres has been demonstrated in the most satisfactory manner by Drs. Gall and Spurzheim.

The cerebellum is situated at the basis of the cerebrum towards its posterior part. (*Fig.* ii. 6, 6.) Its form is elliptical, its largest diameter extending transversely from one side to the other. (*Fig.* ii. 6.) Like the cerebrum it is divided into two lateral halves or hemispheres (*fig.* ii. 6), which are separated by the falx cerebelli. In the centre of its upper surface there is a distinct prominence, termed the vermiform process (*fig.* ii. 7), which may be considered as the fundamental part of the organ, because, in the lower animals, whatever other parts of the cerebellum are absent, this is invariably present, affording thus the nucleus or rudiment of the organ, from which, by the addition of other parts, as the hemispheres or lateral lobes, &c., the more perfect organ of the higher animal is built up.

The external surface of the cerebellum is divided into flattened strata or layers (*fig.* ii. 6), separated by fissures which correspond to the clefts or sulci between the convolutions. The pia mater, bearing the nutrient arteries of the cerebellum, passes between every one of these fissures; while the arachnoid membrane is simply extended over them. If a vertical section be made through either hemisphere of the cerebellum, a thick mass of white substance is seen in the centre, which, as it divides into the several strata, presents an arborescent appearance commonly denominated the arbor vitæ. (*Fig.* iii. 3.) These strata diverge towards the circumference of the cerebellum, and are covered externally by gray substance. (*Fig.* iii. 3.)

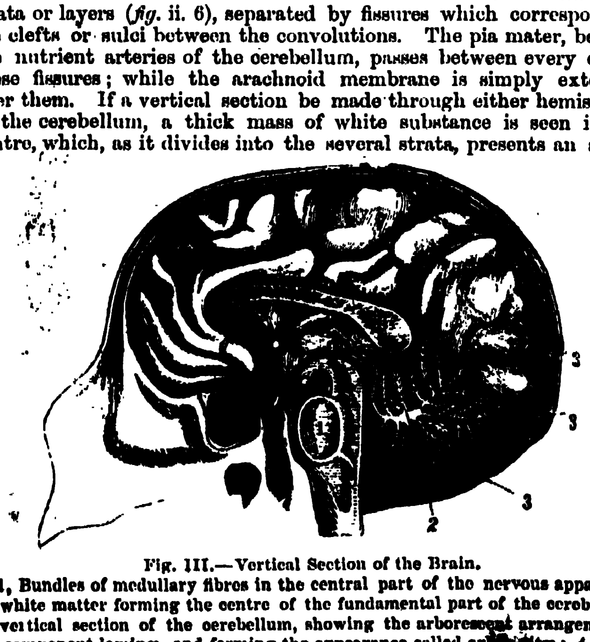

Fig. III.—Vertical Section of the Brain.

1, Bundles of medullary fibres in the central part of the nervous apparatus; 2, white matter forming the centre of the fundamental part of the cerebellum; 3, vertical section of the cerebellum, showing the arborescent arrangement of its component laminæ, and forming the appearance called arbor vitæ; 4, situation of the third ventricle; 5, fibres of white matter, forming the septum lucidum, the medullary layer which separates the two lateral ventricles from each other; 6, fibres of white matter, forming the corpus callosum, immediately beneath which are situated the lateral ventricles; 7, convolutions of the cerebrum.

In front of the cerebellum is placed a large mass of nervous matter, forming a very considerable eminence, commonly termed the tuber annulare, or the pons varolii. (*Fig.* ii. 10.) The external surface of this body is convex, and it is divided into two lateral halves by a middle groove. (*Fig.* ii. 10.) It is joined to the cerebrum by two thick white cords named the crura cerebri, and to the cerebellum by two similar cords named the crura cerebelli. The crura cerebri are continued (from the tuber) outwards and forwards to the under and middle part of each hemisphere of the cerebrum, in which they are lost. In like manner the crura cerebelli are continued outwards and backwards into the hemispheres of the cerebellum, in which they terminate.

The Medulla Oblongata is that portion of the cerebral mass which intervenes between the tuber annulare and the foramen magnum (*fig.* ii. 7): beyond the foramen magnum it takes the name of spinal cord. On the anterior surface of the medulla oblongata there are four eminences contiguous to each other. (*Fig.* ii. 7.) The two internal are named corpora pyramidalia, or the pyramids (*fig.* ii. 8); and the two external the corpora olivaria (*fig.* ii. 9), or the olivary bodies.

If the membranes which invest the medulla oblongata are carefully removed, and its middle groove be gently drawn asunder, there will be discovered four or five bands of white substance ascending obliquely from one side of the medulla to the other. (*Fig.* ii. 11.) These bands on each side decussate, some of them passing above and others below those of the other side, so that they are interwoven like plaited straw. (*Fig.* ii. 11.) These bands are named the decussating bands of the corpora pyramidalia, and their decussation is conceived to explain the phenomenon familiar to the physician and surgeon, that when injury is done to one side of the brain a consequent disturbance of function is manifested on the opposite side of the body.

Taken as a whole, the nervous mass constituting the brain is strictly symmetrical, that is, the different parts of which it is composed are so arranged, that, if the organ be supposed to be divided into two lateral halves by a plane passing perpendicularly through its centre, the parts placed on each side of this plane have a perfect correspondence with each other, and form in fact reduplications of each other. (*Fig.* ii.) The principal parts of the cerebral mass are thus double, but they are all united on the median line with their fellows of the opposite side. This union is effected by medullary bands of various sizes and figures which pass from one to another, called commissures. Thus the double parts of the cerebellum are united by means of the large mass of cerebral matter already spoken of under the name of tuber annulare, or pons varolii. (*Fig.* ii. 10.) The hemispheres of the cerebrum are united chiefly by a broad expansion of medullary matter, which extends transversely across from the bottom of one hemisphere to that of the opposite side, called the corpus callosum, or the great commissure of the brain. (*Fig.* iii. 6, 6.) There are other connecting bands of smaller size by which minor portions of the cerebral mass are placed in communication, into a description of which it is not necessary to enter here.

The cerebral parts are separated from one another at certain places, and the intervals form cavities which are termed ventricles. Of these ventricles there are commonly enumerated four, all of which are in communication with each other. By far the largest of these are the two great cavities called the lateral ventricles, which are situated in the interior of the hemispheres of the cerebrum. Commencing in the fore part of the anterior lobes, these cavities proceed backwards in a direction parallel to each other through the middle into the posterior lobes. Their figure is winding and exceedingly irregular, and they are separated from each other by a tender mass of medullary matter termed the septum lucidum. (*Fig.* iii. 5.) They are lined throughout by a fine transparent membrane, which secretes a fluid that keeps them moist, gives them a bright polished appearance, and prevents them from uniting. This membrane is the pia mater, which is continued from the exterior surface of the brain into these interior cavities; and some anatomists describe the arachnoid membrane as accompanying the pia mater in all its course through the ventricles.

The middle or third ventricle is a vertical fissure between the two large convex eminences called the thalami optici (*fig.* iii. 4), situated in the middle and back part of the lateral ventricles. The fourth ventricle, called also ventricle of the cerebellum, is a cavity of considerable extent situated between the cerebrum, the tuber annulare, and the medulla oblongata.

For a detailed account of the course of the fibres the reader is referred to the work of Drs. Gall and Spurzheim, entitled 'Recherches sur le Système Nerveux en général, et sur celui du Cerveau en particulier,' in which the direction of the cerebral fibres is not only minutely and exactly described, but illustrated by excellent drawings as large as the objects. The course of the fibres that compose the pyramids (*fig.* ii. 8 and *fig.* iv. 1) is as follows:—Immediately before their entrance into the tuber annulare the pyramids are a little contracted. (*Fig.* ii. 8.) As soon as they enter this mass the pyramids are divided into innumerable bundles of fibres (*fig.* iv. 2), which are covered by a thick layer of transverse fibres (*fig.* iv. 2) that come from the cerebellum. (*Fig.* iv. 8.) These fibres of the pyramids, thus increased in number, ascend, and receive at every point of their course fresh accessions, until at their exit (from the tuber) forward and outward they form at least two-thirds of the crura cerebri, as is seen at *fig.* iv. 3. Followed in their course forwards from *fig.* iv. 3, they are manifestly increased at every point by the accession of infinite numbers of fibres. (*Fig.* iv. 4.) At the point (*fig.* iv. 5) the fibres, now exceedingly numerous, manifestly assume a diverging course, proceeding in every direction forwards, upwards, laterally, and backwards. (*Fig.* iv. 5, 6, 7.) At length the radiating fibres, crossing and interlacing each other in all directions, form an expansion or tissue, and, being folded in various ways and covered with gray matter, constitute the convolutions. (*Fig.* iv. 5, 6, 7, 7.) Thus the pyramids, progressively increased and developed, form a large portion of the anterior and middle lobes of the cerebrum. If the corpora olivaria (*fig.* ii. 9) were traced in like manner, they would be found to form the posterior lobes of the cerebrum; and the origin and source of the fibres constituting the main bulk of the cerebellum can be demonstrated with the same clearness and exactness.

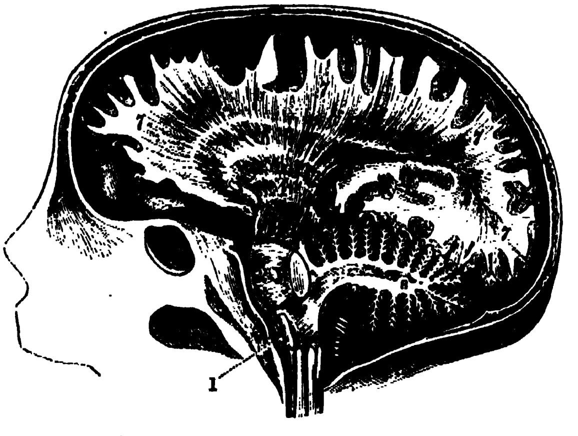

Fig. IV.—Course of the fibres of the Brain.

1, Entrance of the anterior pyramids into 2, the tuber annulare, or pons varolii; 3, fibres of the pyramids much increased as they issue from the tuber annulare; 4, 5, continued increase in the fibres of the pyramids as they advance onwards towards the convolutions; 6, divergence of the fibres of the pyramids; 7, convolutions of the cerebrum, showing their depth, their gray matter, and the sulci between them; 8, cerebellum.

From the preceding account of the structure of the brain, which shows it to be an exceedingly complex organ, it might have been inferred from analogy that it would receive a large supply of blood; but the quantity actually sent to it is far greater than any analogy could have led us to suppose. Haller made a calculation, from which he concluded that one-fifth of all the blood sent out of the left ventricle of the heart is carried to the head, yet the weight of the brain in the human subject is not more than one-fortieth of that of the whole body. Even if this estimate, which is generally thought too large, be reduced to one-tenth, according to the idea of Monro, it will still leave a very great over-proportion. There is no part of the structure of the brain more curious than the various contrivances connected with the circulation through the head, which have for their object the prevention of this prodigious quantity of blood from producing any injurious effects upon the tender cerebral substance, whether by its pressure or by its unequal distribution, in consequence of its stagnating in the vessels, or of its being too violently propelled against them. Many conjectures have been formed respecting the object of furnishing this organ with such an extraordinary quantity of blood, but nothing is really known of the use to which it is applied, though it may be admitted, to give a degree of plausibility to the opinion, that the brain has some analogy to a secreting organ. Without doubt one use both of the ventricles and the convolutions is to afford a more extended surface by which the blood-vessels may enter the cerebral substance at a greater number of points, and consequently in small quantity at any one point, while at the same time they are more firmly supported in their passage by the greater quantity of investing membrane with which they are supplied. [NERVOUS SYSTEM.]

The brain of the vertebrate animals differs considerably from that of man, and more in proportion to their low position in the scale of development. The most obvious distinction between the brain of man and that of the other mammalia is its diminished size in most of the latter. The moment the skull-cap is raised, the difference between the full rounded appearance of the former and the compressed flattened shape of the latter cannot fail to be observed. The convexity of the middle lobes is strangely lessened, and the posterior lobe is in a manner lost in quadrupeds. If the brain is now removed from the cranial cavity, the difference in bulk between that of man and the inferior animals is strikingly displayed. The brain of the ox scarcely weighs a pound: the average weight of the brain of the human being is more than 2¼ pounds.

In man the brain is supposed to constitute about 1-35th part of the weight of his body. In the dog, averaging the different breeds, it is 1-120th part; in the horse it is only the 450th part, in the sheep the 750th part, and in the ox the 800th part.

As an illustration of the greater size and development of the nerves of sense in animals, the olfactory one may be selected. In man, who has other means of judging of the qualities of his food, and of surrounding objects, than by the sense of smell, the olfactory nerve is not one-fourth the size of that of the horse; in the ox, which is not so much domesticated as the horse, and oftener sent into the field to shift for itself, it is considerably larger; it is larger still in the swine, which has to search for a portion of its food buried in the earth, or deeply immersed in refuse or filth; and it is largest of all in the dog, whose acuteness of scent renders him so useful a servant to man.

The different development of the medulla oblongata in different animals may be adduced as another proof of the admirable adaptation of each to the situation which it occupies and the functions which it discharges. The medulla oblongata is the prolongation and condensation of the medullary matter of the brain, and it is the origin of that portion of the spinal cord which is devoted to organic life. In the human being, the breadth of it is only a seventh part of that of the brain; in the horse and the ox, it is nearly a third; and in the dog it is more than a half. In every part of the brain of the quadruped the medullary portion preponderates, and the cineritious is deficient.

In the smaller quadrupeds the comparative size of the brain approaches nearer to that of the human being. In the mouse it is a 43rd part of the weight of the animal.

The brain of the larger birds agrees with that of the mammalia in the smallness of its bulk, compared with the development of the same organ in the human being. The brain of the eagle is not more than a 260th part of the weight of the bird. The brain of the goose is not more than a 360th part. If in some of the lesser birds, as in the chaffinch and the redbreast, it approaches to the proportionate size of that of the human being, it is, as in the smaller quadrupeds, on account of the quantity of medullary matter required for the origins of the nerves; and the cineritious matter forms only a very small part of the brain. The brain of the bird has no convolutions on its surface; no corpora striata in the ventricles; no pons varolii between the brain and the spinal cord; and the origins of the optic nerves are separate from the brain, and lie behind and below it.

In fishes the brain is yet more diminished in proportionate size. In some species it does not constitute a 2000th part of the bulk of the fish. It scarcely half fills the cranial cavity, but is surrounded by a cellular tissue containing a transparent semifluid mass. It singularly varies in different species. It consists of at least four or more rounded eminences, placed in pairs opposite to each other and forming two parallel lines; and there is often only a very slight connection between these lines, or the eminences of which either of them is composed. The two principal hemispheres of the brain and the optic thalami are always present. The olfactory nerves often form a third pair of tubercles anterior to those and the cerebellum, and are always found posteriorly on the mesian line. The optic nerves usually cross each other without any intermingling of medullary matter. The cineritious substance is found in an exceedingly small proportion in the brain of fishes.

There is no brain properly speaking in the *Invertebrata*. In the worm, the upper ganglion of the nervous system, which represents the brain, is placed near to, or may be said to be perforated by, the superior portion of the œsophagus, and thence proceed little white threads or cords, which run along the course of the digestive canal. In insects the upper ganglion usually surrounds the œsophagus, and a ganglionic system of nerves can generally be traced proceeding from it. In the larvæ of insects the brain is inclosed in a horny cavity. The spinal cord proceeding from it pursues its course through the whole of the abdomen, presenting evident ganglia at different points, from which nerves are distributed; while from the intermediate spaces are given out other nerves without ganglia, presenting a rude but satisfactory sketch of the combined systems of sensitive and motor nerves discovered by modern physiologists.

(Quain, *Elements of Anatomy;* Grant, *Outlines of Comparative Anatomy;* Carpenter, *Principles of Physiology.*)

BRAIZE, a Fish. [PAGRUS.]

BRAKES. [PTERIS.]

BRAKES ROCK, the vulgar name for the *Allosorus crispus*, a plant belonging to the natural order *Polypodiaceæ*. *Allosorus* is known by its nearly circular sori, which are at length confluent, and are concealed by the reflexed margin of the frond. *A. crispus* has a slender very brittle stem, which attains a height of from 6 to 12 inches. It grows in stony places on mountains throughout Great Britain.

BRA'MA, a genus of Fishes of the order *Acanthopterygii* and family *Squamipennes*. Dorsal, anal, and ventral fins more or less scaly; body much compressed, somewhat ovate when viewed laterally; the head rather obtusely terminated; mouth when shut almost vertical; teeth slender, placed both in the jaws and palatines; branchiostegous rays seven. But one species of this genus is known, *Brama Raii*. M. Cuvier mentions the Mediterranean as the chief locality for this fish, but at the same time he says that it occasionally wanders into the ocean. It appears however that it is not so local as M. Cuvier supposes, numerous specimens having been found on different parts of our own coasts.

Brama Raii measures from about 1 to 2 feet in length; it is of a deep blue colour, becoming silvery towards the belly. The dorsal fin has 34 rays and the anal 30 rays. The tail is large and forked; pectoral fins rather long and narrow; ventral fins small: the scales extend as far as the jaws. The flesh of this fish is said to have an exquisite flavour. (Yarrell, *British Fishes.*)

BRAMBLE, the wild bush that bears blackberries, belonging to the natural order *Rosaceæ*. [RUBUS.]

BRAMBLING. [FRINGILLA.]

BRANCHIO'PODA, the first order of the division *Entomostraca* [ENTOMOSTRACA], of the class *Crustacea.* [CRUSTACEA.] Dr. Baird, in his 'Natural History of the British Entomostraca,' thus characterises it:—Mouth furnished with organs fitted for mastication; branchiæ many, attached to the feet; body sometimes naked, but most frequently having an envelope in form of a buckler, in some inclosing only the head and thorax, in others the whole body; feet vary in number, all branchiferous; antennæ two- or four-jointed and generally ciliated; eyes sometimes two, or even three, but frequently only one, or so closely approximated as to appear single. They are all free and unattached, swimming at large in water. This division of the *Entomostraca* includes some of the commonest forms, such as those known under the name of *Monoculus* and the various species of *Daphnia*, the water-fleas of popular writers. The following is the arrangement of this order by Latreille, which comprehends the *Lophyropoda* of Baird and others:—

Section I.

Lophyropoda.

Feet never more than six, the articulations more or less cylindrical or conical, and never entirely lamelliform or foliaceous. The branchiæ are not numerous; and there is but one eye. Many have the mandibles furnished with a palpus or feeler, and though M. Straus attributes this organisation exclusively to the genera *Cypris* and *Cytherina*, which compose his order of *Ostrapoda*, the elder Jurine and M. Ramdhor have shown that it is also characteristic of *Cyclops*. The antennæ are almost always four in number, and serve for locomotion. Three groups are arranged under this section.

Carcinoida.

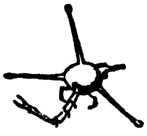
Shell more or less ovoïd, not folded so as to convey the idea of a bivalve, but leaving the lower part of the body uncovered. The antennæ never in the form of ramified arms. Feet ten, more or less, cylindrical or setaceous. Females carrying their eggs in two external bags situated at the base of their tail. Some of this division have two eyes, but the genus *Cyclops* has but one.

a. Two Eyes.

Shell entirely covering the thorax. Eyes large and distinct. Antennæ intermediate, terminated by two bristle-like appendages.

Under this subdivision Latreille places the genera *Zoea*, Bosc; *Nebalia*, Leach; and *Condylura*, Latreille.

In the genus *Zoea* we have an interesting example of the necessity of observing animals not only in one stage but through the whole period of their existence. The *Zoea pelagica* of Bosc, and the other species of the same genus, are now known to be transitionary conditions of the higher forms of *Crustacea.* We are indebted to Mr. V. Thompson of Cork for first having shewn this with regard to *Zoea.* He observed that the members of *Zoea*, from being natatory and cleft, became simple and adapted to crawling only. The animal, when perfected, was found to be a crab. To complete his proof of metamorphosis among the *Crustacea*, he states that he succeeded in hatching the eggs of the common Crab (*Cancer pagurus*), the young of which were found to be similar in form to *Zoea Taurus;* and he thence concluded that the crustaceous decapods generally undergo metamorphoses, being in the first state of their existence essentially natatory; and the greater number of them becoming afterwards in their perfect state incapable of swimming, being then furnished with chelæ (pincers), and with feet almost solely adapted for crawling. Mr. Thompson states that with regard to brachyurous decapods (crabs, &c.) he has ascertained the newly-hatched animal to be a *Zoea* in the following genera: *Cancer, Carcinus, Portunus, Eryphia, Gegarcinus, Thelphusa, Pinnotheres, Inachus*—eight in all; and that in the *Macroura* (lobsters, &c.) he has ascertained that the following seven genera are subject to metamorphosis: *Pagurus, Porcellana, Galathea, Crangon, Palæmon, Homarus, Astacus.* The annexed figure of *Zoea clavata* (Leach), taken by Mr. Cranch in the unfortunate expedition to the Congo under Captain Tuckey in 1816, will give some idea of the general form of *Zoea.*



Zoea clavata.

As an example of this division of Latreille we may give the *Nebalia bipes*, which includes the two species *N. glabra* and *N. ciliata* of Lamarck. This creature has an ovate body of a p[illegible]yellow colour, with a darker longitudinal line along each side; antennæ long, the inferior pair as long as the body, and setiferous; beak of carapace sharp-pointed and moveable; four pairs of natatorial feet of moderate length, and setiferous; caudal appendages rather long, and furnished at the extremity with one long slender seta and three or four short setæ, not plumose. This species is a native of the sea, and has been found on the coast of Devonshire, on the coast of Ireland, and the Shetland Isles.

β. One Eye.

Thorax divided into many segments. The anterior, and much the largest segment, presents a single eye only, placed in the middle of the front between the superior antennæ. *Cyclops* (Müller), which has been so well illustrated by the acute observations of the elder Jurine and of Ramdohr, is the only genus of this subdivision.

The body of the species of *Cyclops* is more or less approaching to oval, soft or rather gelatinous, and is divided into two portions, the one anterior, consisting of the head and thorax, the other posterior, forming what is commonly called the tail. The segment immediately preceding the sexual organs, and which in the females carries two supporting appendages in the form of little feet (fulcra, Jurine), may be considered as the first segment of the tail, which is not always very clearly defined or strongly distinguished from the thorax, and consists of six segments or joints, the second of which in the males is provided on its lower side with two articulated appendages of varied form, sometimes simple, sometimes having a small division at the internal edge, and constituting entirely or in part the organs of generation. In the other sex the female organ is placed upon the same joint. The last segment terminates in two points forming a fork, and more or less bordered with delicate beards or penniform fringes. The anterior portion of the body is divided into four segments, of which the first and by far the largest includes the head and a portion of the thorax, which are thus covered by one scale common to both. Here are situated the eye, four antennæ, two mandibles (internal mandibles of Jurine) furnished with a feeler (which is either simple or divided into two articulated branches), two jaws (the external mandibles, or lip with little beards, of Jurine), and four feet, divided each into two cylindrical stems, fringed with hairs or bearded. The anterior pair representing the second pair of jaws differ a little from the succeeding pair, and are compared by Jurine to a kind of hand. Each of the three succeeding segments serves as the point of attachment to a pair of feet. The two superior antennæ are longest, setaceous, simple, and formed of a great number of small articulations. They facilitate by their action the motion of the body, and perform very nearly the office of feet. The lower antennæ (antennules of Jurine) are filiform, consisting most frequently of not more than four joints, and are sometimes simple, sometimes forked. By their rapid motion they produce a small eddy in the water. In the males the upper antennæ, or one of them only, as in *Cyclops Castor*, are contracted in parts, and exhibit a swelling portion which is followed by a hinge joint. By means of these organs, or of one of them, the males seize either the hind feet or the end of the tail of their females during the season of fecundation, and are thus often found attached. On each side of the tail of the females is an oval bag filled with eggs (external ovary of Jurine), adhering by a very fine pedicle to the second segment, near its junction with the third, and where the orifice of the deferent egg-canal may be seen. The pellicle which forms these bags is only a continuation of that of the internal ovary. The number of contained eggs increases with age. They are at first brown or obscure, but afterwards present a reddish tinge and become nearly transparent, without however increasing in size when the young are about to come forth. When isolated or detached, up to a certain period at least, the germ perishes. A single fecundation suffices for successive generations, and the same female can lay eggs ten times in the course of three months, so that the number of births amounts to something enormous. Thus, taking eight ovipositions and allowing forty eggs for each, it has been calculated that one female *Cyclops* may be the progenitress of four thousand five hundred millions. The time the fœtus remains in the ovary varies from two to ten days, the variation depending on the temperature of the seasons and on other circumstances.

The young at their birth have only four feet, and their body is rounded and tailless. In this state they are the genus *Amymone* of Müller. Some time afterwards (in about fifteen days in the months of February or March) they acquire another pair of feet; they are then the genus *Nauplius* of the same author. After their first moult they assume the form and all the parts which characterise the adult state, but with smaller proportions: their antennæ and feet, for example, are comparatively short. At the end of two more moults they are fit for the reproduction of the species. The greater part of these *Entomostraca* swim upon their backs, darting about with vivacity, and possessing the power of moving either backwards or forwards. Their food generally consists of animal matter in preference to vegetable; but in the absence of the former they feed upon substances of the latter description, and it is said that the fluid in which they live never enters their stomachs. The alimentary canal extends from one extremity of the body to the other. The heart (taking *Cyclops Castor* as the subject) is of a shape approaching to oval, and situated immediately under the second and third segment of the body. Each of the extremities of this organ gives off a vessel, the one going to the head, the other to the tail. Immediately below is another analogous organ, giving off also at each end a vessel supposed to represent the branchiocardiac canals observable in the circulation of the Decapodous *Crustacea.*

The genus *Cyclops* is an inhabitant of the fresh waters; and we select the Common Cyclops, *Cyclops vulgaris*, Leach; *Monoculus quadricornis*, Linn.; *Cyclops quadricornis*, Müller; Monocle à Queue Fourchue, Geoffroy, as an example of the species.

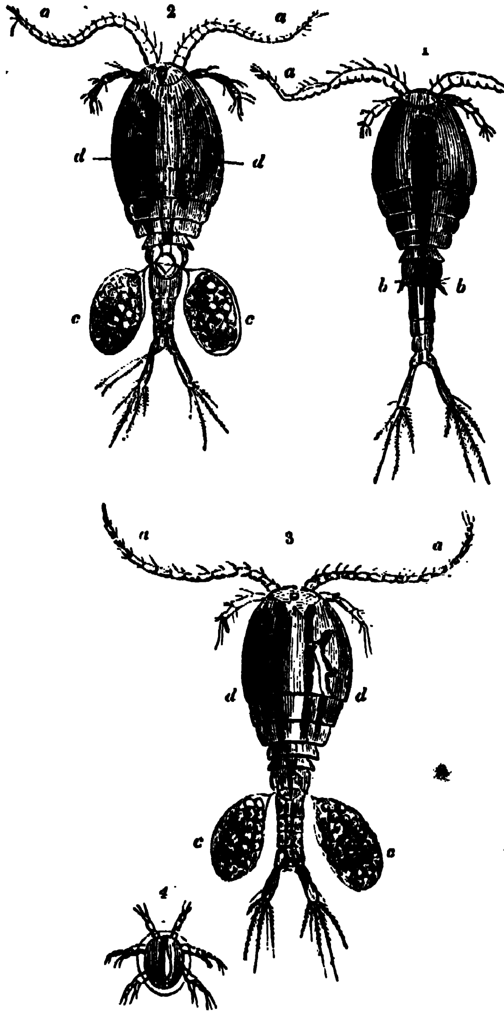
The body of the Common Cyclops has a somewhat swollen appearance, and is formed of four rings, and prolonged to about one-third of its entire length. The tail consists of seven rings. The posterior antennæ (antennules of Jurine) are tolerably large and composed of four joints, the anterior antennæ are thrice the length of the posterior.

There are several varieties.

Var. *a*. Reddish; eggs brown, forming two oblique masses near the sides of the tail. Total length eight-twelfths of a line. This is the *Monoculus quadricornis rubens* of Jurine.

Var. *b*. Whitish or gray, somewhat tinged with brown, rather larger than the preceding. Egg-masses greenish, forming nearly a right angle with the tail. Total length the same as the preceding. This is the *M. q. albidus* of Jurine.

Var. *c*. Greenish. Direction of the two egg-masses intermediate between that of the egg-masses of the two former. Length nine-twelfths of a line. *M. q. viridis* of Jurine.



Cyclops vulgaris, magnified.

1, Male of variety *a*; 2, female of the same; *a a*, antennæ; *b b*, sexual organs of the male; *c c*, external oviparous pouches of the female; *d d*, internal ovaries; 3, a female of variety *c*; 4, a young individual of that variety.

Var. *d*. Smoky red. General form nearly oval. Eggs brown, composing two masses, which cover a great portion of the tail. Length six-twelfths of a line. *M. q. fuscus* of Jurine.

Var. *e*. Of a deeper green than var. *c*. Eggs obscure green, passing a little into rose-colour when hatching is near, forming two masses attached to the tail, and appearing to be incorporate with it. Length the same as the preceding. *M. q. prasinus* of Jurine.

Ostracoda, Latreille; *Ostropoda*, Straus.

The shell of the *Ostracoda* is formed of two pieces or valves representing those of a conchiferous mollusk or bivalve shell, but horny, not testaceous. As in the bivalves, the two pieces are united by a hinge, and when the animal is inactive they close upon and shut in the body and the parts. The feet are ambulatory, six in number, and none are terminated by a digitated swimming organ, nor accompanied by a branchial lamina. The antennæ are simple, filiform, or setaceous. There is but one eye, which is composite and sessile. The mandibles and jaws are furnished with a branchial lamina, and the eggs are situated on the back.

In this division Latreille includes the genera *Cythere*, Müller (*Cytherina*, Lamarck) and *Cypris*. *Cythere* has one eye; three pairs of feet; abdomen short; the inferior or pediform antennæ furnished with one tolerably long curved and jointed filament. The species are inhabitants of the sea. They have not the power of swimming, but are always walking among the leaves or branches of the *Confervæ* and *Fuci*, where they delight to dwell. When shaken out of their hiding places into a tumbler or bottle, they may be seen to fall in gyrations to the bottom, without ever attempting to dart through the fluid, as would be the case with the species of *Cypris*. Upon reaching the bottom they open their shells and creep along the surface of the glass; but when touched or shaken they immediately again withdraw themselves within their shell and remain motionless. Dr. Baird, whose work on the British species contains a fund of information on the habits of the minute family to which these creatures belong, says that the species "are undoubtedly numerous, and the labours of any inquirer after them would assuredly be rewarded with success." He has described fifteen species as inhabitants of the British coasts. Several of the species have been found fossil.

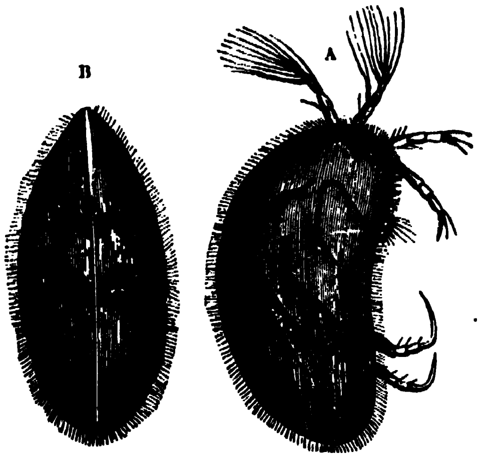
Cypris has two pairs of feet, one pair always inclosed within the shell. The two antennæ are terminated by a pencil of fine hairs. The case or shell is suboval, arched, and protuberant on the back or hinge side, and nearly straight or a little sinuous or kidney-shaped on the opposite edge. A little in advance of the hinge, and upon the mesial line, is the single large blackish round eye. The antennæ, which are inserted immediately below, are shorter than the body, setaceous, composed of from seven to eight joints, of which the last are the shortest, and terminated by a pencil of twelve or fifteen fine hairs, which serve as swimming organs. The mouth is composed of a carinated labrum; of two large toothed mandibles, each furnished with a feeler of three joints, to the first of which a small branchial lamina of five digitations (interior lip of Ramdohr) is attached, and of two pairs of jaws; the two upper, which are much the largest, have on their internal border four moveable and silky appendages, and externally a large branchial lamina pectinated on its anterior edge; the second are formed of two joints, with a short, nearly conical, and jointless feeler, also silky at the end. A sort of compressed sternum performs the office of a lower lip (external lip of Ramdohr). The feet have five joints, the third representing the thigh, and the last the tarsus; the two anterior ones, much stronger than the rest, are inserted below the antennæ, directed forwards with stiff hairs on long hooks collected into a bundle at the extremity of the two last joints: the four following feet are without these appendages. The second pair, situated on the middle of the under side of the body, are directed backwards, curved, and terminated by a long strong hook bent forwards; the two last, never showing themselves beyond the shell, are applied to the sides of the body for the purpose of sustaining the ovaries, and are terminated by two very small hooks. There is no distinct joint observable in the body, which terminates posteriorly in a kind of tail, which is soft and bent upon itself underwards, with two conic or setaceous filaments fringed with three silky hairs or hooks at the end, and directing itself backwards so as to project beyond the shell. The ovaries form two large vessels, simple and conical, situated upon the posterior sides of the body under the shell, and opening, one at the side of the other, at the anterior part of the abdomen, where the canal formed by the tail establishes a communication between them. The eggs are spherical.

These animals swim with more or less rapidity in the still fresh waters or gently-running streams which they inhabit, in proportion as they bring into action the filaments of the antennæ; sometimes they only show one, at others they put them all forth. Latreille thinks that these filaments may also assist in respiration. The two anterior feet are moved with the same rapidity as the antennæ when the animal is swimming; when it creeps over the surface of the water-plants, the progress is slow. The female deposits her eggs in a mass, fixing them by means of a glutinous substance on the water-plants or on the mud. Anchored by her second pair of feet, so as to be safe from the agitation of the water, she is occupied about two hours in this operation, the produce of which, in the largest species, amounts to 24 eggs. Jurine collected some of these at the time of their exclusion, and, after having insulated them, obtained another generation without the intervention of the male. A female which laid her eggs on the 12th of April changed her skin six times between that day and the 18th of May following. On the 27th of the last-named month she laid again, and, two days afterwards, made a second deposit. Jurine concludes that the number of moults in the young state corresponds with the gradual development of the individual. Desmarest considers that they do not undergo a metamorphosis, but that they present on their exclusion from the egg the form which they preserve throughout their life. Their food is said to consist of dead animal substances and of *Confervæ*. In summer, when the heats have dried up the pools, they plunge into the humid mud, and there remain in an apocryphal kind of existence till the rains again restore them to activity.

The recent species are numerous; Jurine described 21. Dr. Baird describes 15 species as British.

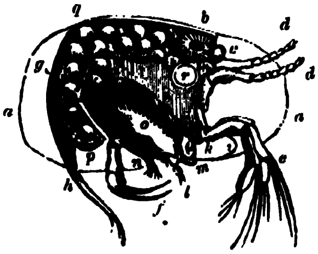
The hard shells of *Cypris* resist decomposition, hence many are fossil.

Cypris Faba, Desmarest, holds a place among the organic remains of the Wealden Rocks of England. Dr. Fitton has recorded it in the Weald Clay of the Isle of Wight, Swanage Bay, &c., and Dr. Mantell in the Hastings Sands. Desmarest notes the species as found in great abundance near the mountain of Gergovie, in the department of the Puy-de-Dôme, and at the Balme-d'Allier, between Vichy-les-Bains and Cussac. Their great fruitfulness and the frequent moults noticed above may account in some measure for the quantities of their petrified exuviæ. *Cypris* has also been found in the Fresh-Water Limestone, beneath the Mid-Lothian Coal-Field, at Burdiehouse, near Edinburgh, and in other districts.



Cypris ornata (magnified).

Shell yellowish-green, banded with green. A, side view; B, view looking upon the hinge. The bands commence behind the eye.



Cypris fusca (magnified), Straus.

Valves brown, kidney-shaped, covered with fine scattered hairs. Antennæ with fifteen fine bristles. In the view the valves are supposed to be removed, the outline *a a* showing their shape and their relative situation; *b*, origin of the hinge membrane; *c*, eye; *d d*, antennæ deprived of their bristles; *e*, feet of the first pair; *f*, of the second pair; *g*, of the third pair; *h*, tail; *i*, labrum; *k*, mandible; *l*, feeler; *m*, jaw of the first pair; *n*, of the second pair; *o*, branchia or gill; *p q*, posterior portion of the left ovary; *r*, the male organ according to Straus.

Cladocera, Latreille; *Daphnides*, Straus.—These minute creatures have a single eye only, and are protected by a shell doubled as it were, but without any hinge, according to Jurine, and terminated posteriorly in a point. The head, which is covered with a kind of beak-like armour, projects beyond the shell. There are two antennæ, generally large, in the form of arms, divided into two or three branches placed on a peduncle fringed with filaments always projecting, and serving the purpose of oars. The feet, four to six pairs, terminated by a digitated or pectinated swimming organ, and furnished, with the exception of the two first, with a branchial lamina. Their eggs are situated on the back, and their body terminates with a sort of tail with two delicate hairs or filaments at the end. The anterior part of the body is somtimes prolonged into the form of a beak, sometimes into a shape approaching that of a head occupied almost entirely by one large eye.

Latreille gives the following sub-genera: *Polyphemus*, Müller; *Daphnia*, Müller; *Lynceus*, Müller (*Chilodorus*, Leach). This division in Baird's 'Entomostraca' includes the following families and genera.

1. *Daphniadæ.*

Daphnia.
Bosmina.
Sida.
Moina.
Macrothrix.
Daphnella.

2. *Polyphemidæ.*

Polyphemus.
Evadne.

3. *Lynceidæ.*

Eurycercus.
Camptocercus.
Alona.
Peracantha.
Chydorus.
Acroperus.
Pleuroxus.

Of these *Daphnia* is the most numerous genus; and though the species are so extremely small, the observations of naturalists, and more especially of Schœffer, Ramdohr, Straus, and the elder Jurine, have rendered its organisation and habits extremely well known. In the species of *Daphnia* one junction of the sexes fecundates the ova for many successive generations, six at least; their moults are very frequent; they lay at first but one egg, then two or three, and so on progressively as they advance in life till their number amounts to 58 in one species (*Daphnia magna*); and the young of the same deposit are generally of one sex, it being rare to find two or three males in a female batch, and vice versâ. As the winter approaches their moults and oviposits cease, and the frost is supposed to destroy them, leaving however the eggs unharmed, which the genial spring season hatches to fill the pools with myriads of *Daphniæ*. Then those who have microscopes will find ample employment for them. Every ditch, every pool, every garden reservoir, will furnish the observer with Branchiopods.

The species are numerous. The most common is the Water-Flea, *Daphnia pulex* of Latreille, *Monoculus pulex* of Linnæus, *Pulex aquaticus arborescens* of Swammerdam, Le Perroquet d'Eau of Geoffroy. Despised as this minute creature may be by those who, like the orientalists, consider size as absolutely necessary to produce grand ideas, it has fixed the especial attention of Swammerdam, Needham, Leuwenhoek, Schœffer, De Geer, Straus, and above all, of Jurine, who, in common with other philosophers of great name, have found as much interesting information regarding the development of animal life in the admirable organisation of these animated specks as is afforded by the largest vertebrated animal. [DAPHNIA.]

Section II.

Phyllopa.

Distinguished by the number of feet, and by the lamella or foliaceous form of the joints, representing, according to Latreille, the *Myriapods* in the class *Insecta*. The eyes are always two in number, formed of a sort of network, and sometimes placed on pedicles; many have besides a single smooth eye.

Ceratophthalma, Latreille, have ten pairs of feet at the least, and the maximum of those organs in this group is said to be 22. There is no vesicular body at their base, and the anterior feet are never so long as the others, nor are they ramified. The body is either inclosed in a shell-case, like a bivalve shell, or naked, the thoracic divisions being each furnished with a pair of feet. The eyes are sometimes sessile, small, and placed very nearly together; sometimes, and indeed most frequently, they are mounted on the extremity of two moveable pedicles. The eggs are either internal or external, and inclosed in a capsule.

α.

Eyes sessile, immoveable; body inclosed in an oval case like a bivalve shell; ovaries always internal.

The sub-genus *Limnadia* of Adolphe Brongniart is an example of this structure. *Limnadia Hermanni* (Adol. Brongn.), *Daphnia gigas* of Hermann, occurs in great numbers in the little pools of the forest of Fontainebleau, and we must refer the reader to Brongniart's Memoir in the 6th vol. of the 'Mémoires du Muséum d'Histoire Naturelle' for its description.

β.

Each eye situated at the extremity of a pedicle on both sides of the head; body naked and annulated throughout its length; no enveloping case or shell; eggs contained in an elongated capsule situated towards the base of the tail, or at the posterior extremity of the body and thorax in those which have no tail.

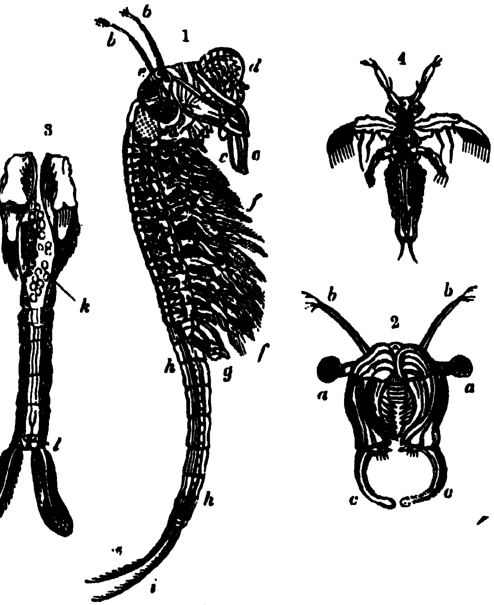
1. With a Tail.

To this subdivision belongs the Brine-Shrimp or Brine-Worm, *Artemia* or *Artemis* of Leach, *Branchipus* of Latreille, and *Chirocephalus* of Benedict Prevost and Jurine. We are now arrived at that development of form in the Branchiopoda where the numerous legs or feet become paddles adapted simultaneously to the purposes of locomotion and respiration.

The Brine-Worm or Brine-Shrimp, *Artemia salina* of Leach, *Cancer salinus* of Linnæus, *Gammarus salinus* of Fabricius, *Artemis salinus* of Leach, *Artemisus salinus* of Lamarck, when full-grown, is about half an inch in length and very transparent: it is said to have been first discovered in the salt-pans at Lymington by Dr. Maty. There these animals are found in myriads, in rapid and continual motion in the salterns, which are the open tanks or reservoirs where the brine is deposited previous to boiling. The brine attains the desired strength by evaporation from exposure to the sun and air in about a fortnight. A pint contains about a quarter of a pound of salt, and in this concentrated solution, which, as Mr. Rackett observes, instantly destroys most other marine animals, the Brine-Shrimp revels. It is further said that these Brine-Worms are never found in the sun-pans where the brine is made by the admission of sea-water during the summer, and which are emptied every fortnight, but only in the pits or reservoirs (clearers) where it is deposited after it is taken out of the pans, and where some of the liquor constantly remains. So persuaded are the workmen of their utility in clearing the liquor, that they are accustomed to transport a few of the worms from another saltern if they do not appear at their own, and they increase greatly in a few days. Little however was known of the natural history of this animal till Mr. Thompson published his interesting observations in the 6th number of his 'Zoological Researches' (1834). He has there described and illustrated the gradual development of the embryo, and the metamorphoses which it undergoes from its first production until it arrives at a perfect or adult state. These, he says, will be found to correspond with those of *Branchipus*, *Chirocephalus*, and *Apus*, animals with which its alliance can no longer be doubtful. *Artemia* bears a long journey very well. We have had a glass jar full of them in their native brine sent to London. They lived a considerable time and were in full life and activity, affording very satisfactory opportunities of observing their habits and of confirming the statements of Mr. Thompson. They are constantly gliding with an even motion in the clear circumambient fluid, sometimes on their backs, sometimes on their sides, sometimes on their bellies, and seem to move with equal facility in every direction. Their transparency and the unwearied undulating motions of their respiratory paddles render them very interesting objects, and convey a deep impression of the harmony of adaptation of members to two such apparently anomalous ends as breathing and locomotion at the same moment.

The salt-pans at Lymington and some salt lakes in Siberia appear to be the only localities where these animals have been hitherto detected.

Branchipus stagnalis of Milne-Edwards, *Cancer stagnalis* of Linnæus, *Gammarus stagnalis* of Fabricius and Herbst, *Apus pisciformis* of Schœffer, who found it in a ditch by the road which leads from Ratisbon to the town of St. Nicholas, *Chirocephalus diaphanus* of Prevost, belongs to this division of Latreille. It is a British animal, and is especially known as inhabiting the pools on the road-side of Blackheath Common. [CHIROCEPHALUS.]



Branchipus stagnalis.

1, Male, magnified; *a a*, composite or network eyes; *b b*, antennæ; *c c*, mandibuliform horns; *d*, proboscidiform moveable tentacula, rolled spirally; *e*, simple rudimentary eye; *f f*, leaf-like natatory feet or oars; *g*, male organs; *h h*, tail; *i*, terminating filaments; 2, front view of the head; 3, tail of the female; *k*, egg-pouch; *l*, female organ; 4, a young *Branchipus* after the first moult.

2. Witho[illegible] Tail.

The genus *Eulimene*, Latreille, belongs to this sub-section. The body is nearly linear, and there are four short antennæ almost filiform, of which the two smallest, which much resemble feelers, are placed at the anterior extremity of the head, which is furnished with two eyes mounted on cylindrical pedicles. The branchial paddles are 11, and immediately behind them is a terminal demi-globose piece in place of a tail, from whence issues a long delicate treadlike process, which may perhaps (according to Latreille) be an oviduct. *Eulimene albida*, whose body is for the most part white, with its posterior extremity black (*Artemia Eulimene*, Leach), the only species described by Latreille, was found in the Mediterranean near Nice.

Aspidophora.

Of this last division of the *Phyllopa*, Latreille says that they have 60 pairs of feet, all furnished near their base with a large oval vesicle, the two anterior feet, which are much the largest, resembling antennæ. A large shell or crust covers the larger portion of the upper part of the body. This shell is free, shield-shaped, notched posteriorly, and bearing anteriorly on a circumscribed space three simple sessile eyes, of which the two anterior are largest and lunated. There are two bivalve capsules containing the eggs, and annexed to the eleventh pair of feet.

Apus productus [BINOCULUS] is an example. Mr. Thompson figures a species, *Apus Guildingii*, from the West Indies, and observes that there appear to be two European species confounded under the specific name *cancriformis*, namely, Schœffer's and Dr. Leach's, which most resemble *Apus Guildingii*, and that described by Savigny, in which the elongated shield entirely covers the natatory members.

Mr. Thompson observes that there is a considerable approximation between *Artemis* and certain *Trilobites* (*Bucephalithus*, &c.), nor can there be any doubt that the analogies of *Branchipus*, *Serolis*, and *Limulus* all contribute to the illustration of that most ancient race of Crustaceans. [TRILOBITES.] (Burmeister, *On the Trilobites*.)

BRANCHIO'STOMA, the name given by Costa to the most anomalous of all living fishes, and indeed of all the *Vertebrata*.

This extraordinary animal was first discovered on the coasts of Britain, a single specimen having been sent to Pallas from the coast of Cornwall during the latter part of the last century. The great naturalist of Russia described and figured it in his 'Spicilegia Zoologica' under the name of *Limax lanceolatus*, believing it to be a mollusk, though remarking in his description of it on the resemblance of some of its characters to those of a fish. It seems to have been lost sight of for more than half a century, and with the exception of a brief reference in Stewart's 'Elements of Natural History' we find no notice of it in any synopsis of animals. In 1834 it was re-discovered by Costa on the Neapolitan shores, who described it in the 'Annuario Zoologico' under the name of *Branchiostoma lubricum*; and some years after in his 'Fauna of the Kingdom of Naples' gave a fuller account of it. Costa first perceived that it was a fish and not an invertebrate animal, and remarked its affinity to the Cyclostomatous fishes. In 1836 Mr. Yarrell gave an account of it in his 'History of British Fishes' under the name of the Lancelet (*Amphioxus lanceolatus*). He had not then met with Costa's account of it. He figured and described it from a specimen found by Mr. Couch at Polperro in Cornwall, the first taken in that locality since its original discovery there. Mr. Yarrell gave the first correct notice of the chorda dorsalis and vertebral column. About the same time, singularly enough, considering how long it had escaped notice since the days of Pallas, it was taken by several naturalists on the coasts of Sweden. Lundevall and Loven found it in Bohuslan in 1834, but did not give an account of it till 1841. Retzius had it from the same locality, and published a notice of it in the 'Berlin Proceedings for November,' 1839, in which also is a communication on the same subject by Professor J. Müller. Rathke gave an account of its structure in 1841. In the same year Mr. J. Goodsir published an elaborate memoir on its anatomy in the 'Transactions of the Royal Society of Edinburgh' for 1841, being the result of his examination of two examples taken in the Irish Sea by Professor E. Forbes in 1837. In 1842 a most valuable memoir on this animal was read before the Royal Society of Berlin by Professor J. Müller, and this paper beautifully illustrated appeared in the volume of 'Transactions' of that society published in 1844.

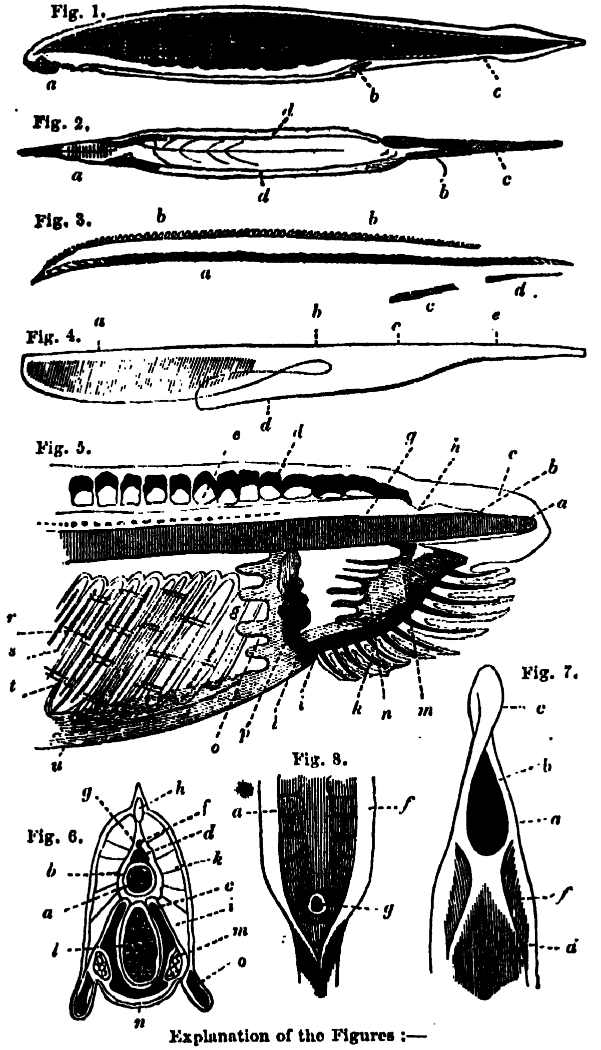
Besides the instances of its capture above mentioned it has been since taken by Mr. MacAndrew on the west coast of Scotland, and by Professor Edward Forbes in the Ægean Sea, and by those gentlemen on the south coast of England in 1846.

The great interest which attaches to this fish depends on the strangeness of its anatomical characters, the unexampled degradation of its organisation among the *Vertebrata*, and the link which it forms between the highest of animals and some of the lowest. A vertebrated animal without a brain, a fish with the respiratory system of a mollusk, and the circulatory system almost of an Annelide, presents a combination of characters which must excite the wonder and interest equally of the physiologist and the systematic naturalist. Scarcely any animal yet discovered is so likely to change received views of classification and relative order of characters as the Lancelet. As yet however it has attracted but little attention among zoologists, though the physiologists and anatomists have fully perceived its value. For these reasons we shall give a full account of what is now known respecting its external character, structure, and habits.

The usual size of the Lancelet is about 2 inches in length; the height to the length being as 1 : 10, and the breadth to the length as ¾ : 10. It is of a lanceolate form tapering to each extremity, and riband-like. Anteriorly it terminates in a head scarcely distinguishable from the body, apparently pointed, but when examined closely seems to end in a rounded and somewhat spathulate rostrum, beneath which is the mouth, a longitudinal opening, fringed on each side by a row of long filaments which can close in and clasp alternately, so as to protect the oral opening. Along the back runs a continuous fin, which dilates near the sharp posterior extremity on each side so as to form a sort of caudal fin. Near the tail opens the vent, in front of which is a median fin continued to another opening situated a little behind the centre of the body (porus abdominalis), and serving as an outlet for the genital products. Continued from this forwards nearly to the mouth are two strong lateral folds, mistaken by Pallas for the margins of a ventral disk, and hence leading him to consider the animal a Gasteropodous Mollusk. The entire animal is translucent and of a silvery whiteness, its sides being marked by the indications of the lateral ichthyic muscles, which give it the aspect of a small sand-eel.

Organisation. Skeleton.—The osseous system consists of a chorda dorsalis tapering at both ends, and, strange to say, not presenting the slightest vestige of a cranium, and of the germs of superior and inferior inter-spinous bones and fin-rays in the most rudimentary state. The chorda dorsalis is composed of from 60 to 70 vertebræ.

which are also in a rudimentary state, and little more than indicated. "The chorda dorsalis," to quote Mr. Goodsir, "is formed externally of a fibrous sheath, and internally of an immense number of laminæ, each of the size and shape of a section of the column at the place where it is situated. When any portion of the column is removed these plates may be pushed out from the tubular sheath like a pile of coins. They have no great adhesion to one another, are of the consistence of parchment, and appear like flattened bladders, as if formed of two tough fibrous membranes pressed together." Besides the skeleton of the nervous system there is a hyoid apparatus forming the armature of the mouth, and consisting of two sets of 17 articulated pieces, from each of which, except two, a ray proceeds. These rays form the oral cirrhi. Müller takes a different view of this structure, maintaining that it corresponds neither to the jaw-bone nor to the hyoid apparatus in other animals, but is analogous to the cartilaginous ring of the mouth of the lamprey and the Myxinoid fishes, a system peculiar to that family. There is also in the Lancelet a series of fine, transparent, cartilaginous, hair-like ribs, 70 to 80 on each side, forming a cage for the protection of the branchial cavity.



Explanation of the Figures :—

Fig. 1. The Lancelet, a little larger than life. *a*, the mouth; *b*, porus abdominalis; *c*, the vent.

Fig. 2. View of the animal from beneath. *a*, the mouth; *b*, porus abdominalis; *c*, vent; *d d*, ventral folds.

Fig. 3. The neuro-skeleton of the Lancelet, consisting of—*a*, the chorda dorsalis; *b b*, the vesicular germs of the dorsal fin-rays; *c*, those of the anterior, and *d*, those of the posterior anal fins (from Goodsir).

Fig. 4. The intestinal system. *a*, the branchial sac; *b*, the œsophagus; *c*, greener and wider part of the intestinal canal; *d*, cæcum; *e*, narrower and posterior part of the intestinal canal.

Fig. 5. Anterior extremity of the body of a young animal (from Müller). The lateral muscles are omitted in order to show more clearly the other parts. *a*, chorda dorsalis; *b*, its sheath; *c*, rounded anterior extremity of the body, terminating in the dorsal fin; *d*, cellular dorsal fin-rays; and *e*, their contents; *g*, spinal marrow; *h*, eye; *i*, labial cartilages; *k*, cirrhi of the mouth; *l*, a muscle of the labial cartilages, arising from the fringed fold between the cavity of the mouth and branchial cavity; *m*, wall of the mouth; *n*, finger-formed figures on the wall of the mouth (ciliated organs); *o*, fringed fold between the oral and branchial cavities; *p*, heart-like arch of the aorta, connecting arch between the branchial heart and aorta; *q*, anterior and superior part of the branchial sac, in which the branchial slits are wanting; *r* and *s*, branchial ribs; *t*, branchial slits; *u*, walls of the belly.

Fig. 6. Transverse section of the body (from Müller). *a*, chorda dorsalis; *b*, its sheath; *c*, membranous layer; *d*, spinal marrow, and *f*, canal above it; *g* and *h*, section of fin-rays; *i*, lateral muscles; *k*, intermuscular ligament; *l*, branchial sac; *m*, ovaria; *n*, wall of belly; *o*, lateral ventral folds, with their canal.

Fig. 7. View of the anterior part of the body from beneath. *a*, mouth; *b*, cirrhi; *c*, snout; *d*, ventral wall; *f*, lateral ventral fold.

Fig. 8. View of the underside of the body in the region of the porus abdominalis. *a*, ovary; *f*, lateral ventral folds; *g*, porus abdominalis.

Nervous System.—The spinal cord extends the whole length of the spine, but is not quite so sharp at the fore-end as behind. It presents no trace of a brain. From 55 to 60 nerves pass off from each side of it, which do not arise by double roots. The details of this important part of the animal's anatomy are fully given by Mr. Goodsir. Müller and Rathke have observed the existence of rudimentary eyes, consisting of a small black spot of pigment, but not furnished with any optical apparatus. No traces of organs of smelling or hearing have been met with.

Vascular System.—The observations of Müller having been made on the living animal, he was enabled to pursue this part of its organisation further than the other observers. According to him the vascular system of this animal corresponds in general arrangement with that of fishes, differing however in regard to the heart from that of all other vertebrate animals, and displaying a striking accordance with that in worms; for the hearts in the *Branchiostoma* are not only more divided than in other animals of its class, but present entirely the form and distribution of blood vessels, and extend over wide spaces. The blood is white.

The Respiratory System is constituted by the anterior extremity of the intestinal tube, the walls of which are clothed with vibratile cilia, and protected and adapted to their office by the peculiar cage-like skeleton already mentioned, which is further strengthened by transverse cartilaginous rods, between which are numerous clefts, their openings protected by vibratile cilia. This was first made known by Müller, who described also a curious apparatus of finger-shaped wheel-organs and fringed folds placed at the entrance of the branchial cavity, and marking the commencement of the ciliated portion of the intestinal canal of which the branchial sac forms a part. At the end of the branchial sac is the porus abdominalis, an opening which serves equally respiratory and genital purposes.

The Digestive System consists of an intestinal canal and a cœcum, both of which are ciliated. The latter is considered by Müller to be a liver, but the office of a liver appears to be performed equally by the other parts of the intestines.

The Reproductive System is imperfectly known. As far as it has been observed it appears in the form of certain bean-shaped bodies attached to the inner surface of the lining of the abdomen on the outside of the branchial canals. Müller distinguishes the two sexes, but this part of the history of the Lancelet demands further investigation. It is not impossible that the two membranous folds of the abdomen and their canals may be connected with this system, and serve marsupial purposes. This remark, however, we merely throw out as a suggestion.

The Muscular System is highly symmetrical, and consists of a series of lateral muscular bundles corresponding in number, size, and position to the vertebræ of the chorda dorsalis, and bearing a general resemblance to the lateral muscles of the higher fishes. Müller classes the muscles of the Lancelet under the heads of—1st, lateral muscles; 2nd, abdominal muscles; 3rd, muscles of the oral ring and tentacula; 4th, muscles of the ring between the oral cavity and branchial sac; and, 5th, muscles of the branchial apparatus. The skin is thin, tough, and scaleless.

Habits.—The Lancelet lives in sandy ground at a depth of between 10 and 20 fathoms water. It probably buries itself in the sand. When taken it swims rapidly with a snake-like motion, but after a time settles down, unless disturbed, lying flat on its side. It is very tenacious of life. We have had it for three hours in a watch-glass under the microscope, at the end of which time when disturbed it seemed as lively as at first. It dislikes the light. It bears handling without injury. Its food was found by Müller in the intestinal canal of some of the specimens he examined: it consisted of infusorial animalculæ. The Lancelet does not swallow but simply imbibes its food.

General Remarks.—"*Branchiostoma*," says Müller, "is evidently a vertebrated animal and a fish. It is distinguished from all other *Vertebrata* by its peculiar circulatory system, and by the absence of a distinction between the brain and spinal marrow; from all other fishes by the extraordinary number of branchial ribs, by the union of the branchial and ventral cavities, and by the combination of the respiratory opening with the ventral opening." Müller considers it connected with the Cyclostomatous fishes through the peculiar characters of its chorda dorsalis and the absence of jaws, but as inferior to them in the absence of a distinct brain and in the peculiarities of its respiratory system. "The *Branchiostoma*," he concludes, "ranks next the Cyclostomatous fishes, but not among them, being removed from them by distinctions which are greater than the differences between fishes and naked amphibia."

"Viewed as an entire animal," writes Mr. Goodsir, "the Lancelet is the most aberrant in the vertebrate sub-kingdom. It connects the *Vertebrata* not only to the Annulose animals, but also through the medium of certain symmetrical *Ascidiæ* (the genus *Pelonaia* of Forbes and Goodsir) to the Mollusks. We have only to suppose the Lancelet to have been developed from the dorsal aspect, the seat of its respiration to be transferred from its intestinal tube to a corresponding portion of its skin, and ganglia to be developed at the points of junction of one or more of its anterior spinal nerves, and inferior branch of its second pair, to have a true Annulose animal, with its peculiar circulation, respiration, generative organs, and nervous system, with supra-œsophageal ganglia and dorsal ganglionic recurrent nerve."

Taking all we know of the structure of this truly wonderful animal into consideration, we are inclined to regard it as the relic of some great order of Fishes, which in their organisation brought down the Vertebrated series to a parallel with the lower forms of *Mollusca*, and which became extinct in some former epoch of the world's geological history, and from the unpreservable character of their bodies, and the absence of hard parts, left "not a wreck behind." The more we know of nature the more are we convinced that there are no isolated organisms; that beings apparently anomalous are members of orders either partially known or for the most part extinct. Of all anomalous creatures the *Branchiostoma* is the most so, and it is much more consistent with the principles of scientific zoology to admit it as the type of a distinct order among fishes than to attempt to place it among defined groups. The strange combination of characters which it presents—a vertebrated animal without a brain, having the respiratory apparatus of an Ascidian Mollusk, and a ciliated intestinal cavity—if it does almost warrant its erection into the type of a class by itself, certainly is sufficient and more than sufficient to constitute it the type of an order in the lowest of the vertebrate classes.

BRANCHITE, a mineral belonging to the Resin series, and found with Coal.

BRAND, or BURN, a disease in vegetables by which their leaves and tender bark are partially destroyed as if they had been burnt; hence the name of this disease, which is called Brûlure in French. It has been observed that after the leaves have been wetted by dews or gentle rains so that drops adhere to them, and a bright sunshine has succeeded, every spot to which the water had adhered lost its natural colour, and became of a dark or yellow hue; and on closer examination it was found that the organisation had been partly destroyed, and that these spots no longer possessed the power inherent in healthy leaves of exhaling the water which circulates through them. When this disease is extensive, and attacks the bark as well as the leaves, it frequently causes the death of the plant, and at all events enfeebles its growth and prevents its perfect fructification. The cause of this, like that of most diseases which are common to plants, has been vulgarly ascribed to some unknown atmospheric influence; and various guesses have been made, which for the most part have little or no foundation. That which appeared most plausible was, that the drops of water being apparently globular, collected the light of the sun into a focus, and produced a sufficient degree of concentration of the calorific rays to burn the tender substance of the leaves. A little reflection will soon convince us that this will not bear examination. The drops which adhere to the leaves and the bark are not globes, but at best flattened hemispheres, and consequently cannot collect the rays of the sun into a focus on the surface to which they adhere; besides, the spots are as large as the diameter of the drops, so that all the surface that has been covered with water is injured; whereas the focus of a globe, such as would actually burn the leaf, must be very small in proportion to the lens which concentrated the rays. It is much more probable that the effect of the water on the tender epidermis of the leaf or bark to which it adheres is similar to that which it has on vegetable matter infused in it; it softens and dissolves a portion of it, especially when the temperature is somewhat raised, and destroys the vitality. (De Candolle, 'Physiologie Végétale.')

It is a fact that the principal mischief arises from a sudden change of temperature soon after sunrise, especially when there has been a heavy dew or hoar-frost in the night; and careful gardeners brush off the drops from their delicate plants before sunrise to guard against the Brand. Every drop which falls on the leaves of tender plants from the glass which covers a hotbed in which they grow produces a disease exactly similar to that which we have been describing; and although the vapour of fermenting dung has a pungent ammoniacal smell, it will be found that the water condensed on the glass is nearly pure, and can have no peculiar corroding effect. It acts therefore simply as a dissolvent, and by stopping the evaporation, which is always rapid from the leaves of plants in a hotbed, produces a derangement in their functions, and ultimately disease.

BRANK-URSINE. [Acanthus.]

BRANTAIL, the Redstart. [Sylvia.]

BRA'SSICA, a genus of Cruciferous plants, comprehending among other species the Cabbage, Cauliflower, Broccoli, Borecole, Rape, Turnip, Colza, and the like. It is distinguished from other Cruciferous genera by the following characters:—Its seeds contain an embryo, the radicle of which is embraced in the concavity of the folded cotyledons. Its pod is long, slender, and many-seeded. The seeds are spherical. The calyx is equal at the base, and slightly spreading; the petals are undivided; the stamens entire.

B. oleracea, the Wild Cabbage, is met with in abundance upon the cliffs of many parts of Europe; commonly in the south part of European Turkey (especially about Mount Athos), on the coast of Kent near Dover, and on that of the Isle of Wight, Cornwall, Wales, and Yorkshire. In other places it forms a broad-leaved glaucous plant, with a somewhat woody stem, having but slender likeness to its cultivated progeny; and it is difficult to conceive by what original discovery the species was brought under the influence of domestication so as to have been prepared for the numerous changes and improvements it had to undergo before the races of Cabbages, Savoys, Borecoles, Cauliflowers, and Broccolis could have been produced.

B. campestris, the Wild Navew or Turnip, has its leaves lyrate, dentate, somewhat hispid; upper leaves ovate, acuminate, deeply cordate, amplexicaul, glabrous. It grows by the sides of rivers, by ditches, in marshes, and the borders of fields in many parts of England. It is believed to have been the Γογγολὶς of Theophrastus. This is looked upon as the original of the Swedish Turnip, whilst a variety, regarded by some botanists as a species, with a caulescent fleshy root, called *B. Rapa*, is supposed to be the origin of the Common Turnip.

B. Napus, the Rape, Colza, or Coleseed, has the lower leaves lyrate, dentate, glabrous; upper leaves oblong, somewhat narrowed below, with a dilated cordate semi-amplexicaul base. It is difficult to find any character by which to distinguish this plant from the preceding. In fact some botanists regard *B. Napus* as nothing more than a variety of *B. campestris*.

B. monensis has the leaves stalked, all deeply pinnatifid; the lobes oblong, unequally toothed, those of the upper leaves linear. The stem of this plant is prostrate, and the flowers yellow. It is found on the western coasts of Great Britain.

BRASSICA'CEÆ, the name given by Dr. Lindley to the natural order *Cruciferæ*. [Cruciferæ.]

BRAUNITE, a native Protoxide of Manganese, containing 79 per cent. of Manganese. It is a dark brownish-black, with a sub-metallic lustre. It has a hardness from 6 to 6·5, and specific gravity 4·8. It is found in Piedmont and Thuringia.

BRAYERA, a genus of plants belonging to the natural order *Rosaceæ*. One of the species, *B. anthelmintica*, yields the anthelmintic remedy known by the name Cusso, Cabotz, or Kousso. Although its anthelmintic virtues have been long known, it has only been recently introduced into Europe. The plant is a native of Abyssinia. [Kousso, in Arts and Sc. Div.]

BRAZIL-NUTS. [Bertholletia.]

BRAZIL-WOOD, the wood of *Cæsalpinia Brasiliensis*. [Cæsalpinia.]

BREAD-FRUIT. [Artocarpus.]

BREAM, a name given more especially to the Carp-Bream, but applied to several other kinds of fish. It is more especially adopted to designate the species of the genus *Abramis*, belonging to the division of Abdominal *Malacopterygii* and the family *Cyprinidæ*. The chief distinguishing characters of this genus consist in the deep and compressed form of the body; the great convexity of the dorsal and abdominal line; the base of the dorsal fin being short, placed behind the line of the ventrals; the long anal fin; and the absence of either strong horny rays or barbules.

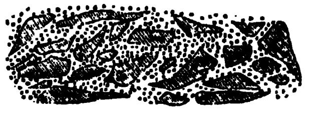
A. Brama, the Bream or Carp-Bream, may be known by its yellowish-white colour, which becomes yellowish-brown by age. The irides are of a golden yellow, the cheeks and gill-covers silver-white; fins light-coloured, the pectoral and ventral fins tinged with red; the dorsal, anal, and caudal fins tinged with brown. The Bream is an inhabitant of many of the lakes and rivers of the continent of Europe generally as far north as Norway and Sweden. It thrives best in this country in large pieces of water or in the deep and most quiet parts of rivers that run slowly. It occurs near London in the Mole and the Medway, also in the Regent's Canal. Bloch states that the number of ova in the female is 130,000. The flesh of the Bream is generally considered insipid, although, on account of the sport it affords the angler, it is a good deal sought after.

A. blicca, the White Bream or Bream-Flat, differs from the Carp-Bream of the same size, in having the head larger and the fleshy portion of the tail deeper. The number of the rays in the pectoral and anal fins differs considerably from those of the Carp-Bream. The pectoral fin of the White Bream has three rays and the anal fin five rays less in number than the Carp-Bream. The general colour of the sides is silvery-bluish white, without any of the yellow-golden lustre observable in the last species. The irides slivery-white, tinged with pink. This fish has never been taken of so large size as the Carp-Bream. It has been described by Bloch, who says it is very common on the continent. It is also found in most of the lakes in Sweden. In England it is not generally known. Mr. Jenyns has recorded its presence in the Cam, and Dr. Lankester took it in large numbers in a piece of water at Campsall near Doncaster. Mr. Lubbock has also taken it near Norwich. It varies very much in its characters, but is undoubtedly a distinct species.

A. Buggenhagii, the Pomeranian Bream. This species of Bream is at once distinguished from the preceding by the greater thickness of its body, by the scales being larger in proportion to its size, the anal fin being shorter, and having a smaller number of rays. Bloch records it as being common in Swedish Pomerania. It is even more rare in England than the last species. (Yarrell, *British Fishes.*)

BREATHING-PORES, microscopic apertures in the cuticle of plants. [STOMATES.]

BRE'CCIA, an Italian word literally signifying "an opening or breaking in any substance," is employed in geology to designate a rock composed of angular fragments of a pre-existing rock, or of several pre-existing rocks, united by a cement of mineral matter that may vary from compact to friable. Thus, as in the annexed diagram, the fragments (which are shaded) may be composed either of angular portions of quartz rock, or any other single rock, united by a cement (which is dotted) formed of the hard siliceous substance named chert, or any other hard mineral substance; or the fragments may be angular portions of many rocks, such as a mixture of pieces of slate, porphyries, limestones, granites, or others, united by a friable sandstone or any other soft mineral substance.



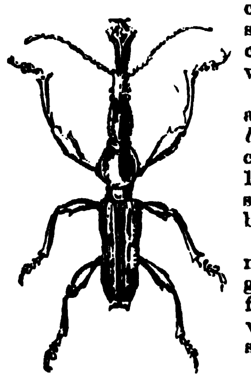
The term Breccia has been adopted from the well-known Breccia marble, which has the appearance of being composed of fragments joined together by carbonate of lime, infiltrated among such fragments after the latter were produced by some disrupting force.

Breccias inform the geologist that the pre-existing portions of rocks included in them have not been exposed to considerable friction, which would have rounded off the angular parts; as has happened in the case of pre-existing pieces of rocks included in conglomerates. [CONGLOMERATE.] Hence the geologist may expect to find the rocks, whence the angular fragments of a breccia are derived, not far distant from the breccia itself, while the rounded pebbles contained in a Conglomerate may have been transplanted from considerable distances.

BREISLAKITE, a mineral which occurs crystallised in delicate capillary crystals of a reddish-brown or chestnut-brown colour, bent and grouped like wool. Its fibres are flexible. It has a metallic lustre. It is found at Vesuvius and Capo di Bove, near Rome, forming woolly coatings in the cavities of lavas. It contains silica, alumina, and oxide of iron.

BRENTI'DES, a family of Coleopterous Insects, belonging to the section *Rhynchophora* and sub-section *Recticornes.* Distinguishing characters:—Body much elongated; tarsi with the penultimate joints bilobed; antennæ filiform, or in some with the terminal joint formed into a club; proboscis projecting horizontally, generally long; in the male longer than in the female; palpi minute.

The insects constituting this family are among the most remarkable of the Beetle Tribe, and are almost entirely confined to tropical climates; only one species has yet been discovered in Europe. But little is known of their habits, except that they are generally found crawling on trees, or under the bark, and sometimes on flowers. The most common colouring of the species is black, or brown, with red spots and markings.



Brentus Temminckii (Klüg).

The four principal genera of the *Brentides* are as follows: — *Brentus, Arrhenodes, Ulocerus,* and *Cyclas.* The genus *Brentus* is chiefly distinguished by having the antennæ 11-jointed, either filiform or sometimes slightly enlarged towards the apex, and the body linear.

Brentus Temminckii (Klüg), one of the most remarkable species of the tribe, will give an idea of their general form. It is found in Java, and is of a blackish colour varied with red markings, and has deeply-striated elytra.

In the genus *Arrhenodes* the rostrum is short, and terminated by two distinct mandibles, which are straight and project considerably in the males. The species inhabit North America, and one is found in Europe, *A. Italica.*

Ulocerus has the antennæ 9-jointed; the last of which forms a club.

Cyclas has the antennæ 10-jointed; the terminal joint forms an oval club; the thorax is indented in the middle, and the abdomen is of an oval form.

BRETT. [RHOMBUS.]

BREUNNERITE is a native Carbonate of Magnesia and Iron. It occurs crystallised. Its primary form is an obtuse rhomboid. The cleavage perfect, parallel to the primary planes. Colour yellow of different shades, and black; streak white; fracture flat conchoidal; hardness 4·0 to 4·5; its lustre is vitreous, sometimes inclining to pearly; it is transparent and translucent. Specific gravity 3·0 to 3·2. Found at Zillerthal in Salzburg and other places in the Tyrol. It has been analysed by Stromeyer and contains

Carbonate of Magnesia	86·05
Carbonate of Iron	13·82
Carbonate of Manganese	0·69

BREXIA'CEÆ, *Brexiads,* the Brexia Tribe, a natural order of plants belonging to the polycarpous group of Monopetalous Exogens. This order was constituted by Lindley in the first edition of his 'Natural System of Plants.' The following is his description of the order:—Calyx inferior, small, persistent, 5-parted, æstivation imbricated; petals 5, hypogynous, imbricated in æstivation; stamens 5, hypogynous, alternate with the petals, arising from a narrow cup, which is toothed between each stamen; anthers oval, innate, 2-celled, bursting longitudinally, fleshy at the apex; pollen triangular, cohering by means of fine threads; ovary superior, 5-celled, with numerous ovules attached in two rows to placentæ in the axis; style 1, continuous; stigma simple; fruit drupaceous, 5-celled, many seeded; seeds indefinite, attached to the axis with a double integument, the inner of which is membranous; no albumen; cotyledons ovate, obtuse; radicle cylindrical, centripetal. The species are trees with nearly single trunks; the leaves are coriaceous, alternate, simple, not dotted, with deciduous minute stipules; the flowers are green, in axillary umbels, surrounded by bracts on the outside.

Dr. Lindley remarks that the habit of *Brexia* is that of some *Myrsinaceæ,* especially of *Theophrasta,* from which it differs in being polypetalous, and the stamens being alternate with the petals. Its relations are also strong with *Rhamnaceæ* and *Celastraceæ,* but its stamens are hypogynous, and its seeds indefinite. Some resemblance to *Anacardiaceæ* may be seen in the resinous appearance of the young shoots, and in its habit. It agrees with *Pittosporaceæ* in its hypogynous definite stamens, its polyspermous fruit, and alternate undivided leaves. There are three species of *Brexia,* all of them elegant trees with a fine foliage. They grow well in a mixture of turfy loam and peat; and cuttings with their leaves not shortened strike readily in sand under a hand-glass in heat, or a leaf with a bud attached will grow. The leaves are covered with a resinous matter which causes rain to run off them immediately, and thus induced Du Petit Thouars to give these plants the name of Brexia, from Βρέξις, which signifies 'a wetting.' In gardens they are commonly called Theophrastas, but they differ considerably from that genus. All the species of *Brexia* are natives of Madagascar. The other genera of this order are *Ixerba, Argophyllum,* and *Roussea.* There are but six species in all.

(Loudon, *Encyclopædia of Plants;* Lindley, *Vegetable Kingdom;* Don, *Gardener's Dictionary.*)

BRILL. [RHOMBUS.]

BRIMSTONE. [SULPHUR.]

BRINE-SHRIMP. [BRANCHIOPODA.]

BRITTLEWORTS. [DIATOMACEÆ.]

BRIZA, a genus of Grasses belonging to the tribe *Festucineæ.* It has nearly equal broad 3-ribbed glumes; 3-8 flowers, densely imbricated in a short distichous spikelet; the outer palea navicular, heart-shaped, obtuse, rounded on the back, unarmed; the glumes and paleæ membranous with a scarious margin; terminal styles. Two species of this grass are natives of Great Britain, the *B. minor* and *B. major.* They are known by the common names of Quaking-Grass and Maiden's-Hair. Their dense clusters of flowers are hung upon the ends of a very delicate filamentous peduncle, forming an elegant panicle which shakes with the slightest breath of air, hence the name Quaking-Grass. Both the species grow in pastures, but do not yield much nutriment for animals which feed upon them. (Babington, *Manual of Botany.*)

BROADBILL. [DUCKS.]

BROCCOLI. [BRASSICA.]

BROCHANTITE, a native hydrous Sulphate of Copper. It occurs crystallised, and has for its primary form a right rhombic prism. The cleavage is obtained with difficulty in the direction of the lateral faces of the primary form. The colour is emerald-green; fracture uneven; hardness 3·5 to 4·0; lustre vitreous; translucent, transparent. Specific gravity 3·78 to 3·87. It is found in Siberia. The following analysis is by Magnus:—

Sulphuric Acid	17·43
Oxide of Copper	66·93
Oxide of Tin	3·14
Oxide of Lead	1·04
Water	11·91

BROME-GRASS. [BROMUS.]

BROMELIA'CEÆ, or BROMELIÆ, *Bromelworts,* the Pine-Apple Tribe, a natural order of Endogenous plants, taking its name from the genus to which the pine-apple was once incorrectly referred [ANANASSA], and consisting of herbaceous plants, remarkable for the hardness and dryness of their gray foliage. They occur in great abundance in the tropical parts of the New World, or in such extra-tropical countries as, owing to local circumstances, have a climate of a tropical nature. Sometimes they are found growing on the earth in forests, but more commonly they spring up from the branches of trees, round which they coil their simple succulent roots, vegetating upon the decayed matter they may find there, and absorbing their food in a great measure from the atmosphere. Their leaves are always packed together so very closely at the base as to form a kind of cup, in which water collects; so that the traveller who ascends the trees on which they grow, if he upset one of these plants, as he easily may, is unexpectedly deluged by a shower, the source of which he would not have suspected. The flowers of most are pretty, and of some of them remarkably handsome and sweet-scented; but the fruit is in no case of any value except in the genus *Ananassa*. *Bromeliaceæ* may be shortly described as scurfy-leaved hexandrous endogens, with distinct calyx and corolla, an inferior ovary, and seeds whose embryo lies in mealy albumen. They are known from *Amaryllidaceæ* by the last circumstance, by their hard scurfy leaves, and epiphytal habit; from *Burmanniaceæ*, by their leaves not being equitant, nor their fruit winged; and from *Taccaceæ* by all their habit, and their fruit being 3-celled, with central placentæ.

The green fruit of the wild Pine-Apple, as well as *Bromelia Pinguin* and others, are used as anthelmintics and diuretics in the West Indies. The leaves of *Tillandsia usneoides* are used for stuffing mattresses. A gum flows from the spike of *Puya lanuginosa*. A dye is extracted from the root of *Billbergia tinctoria*. Muslin has been manufactured from the fibres of the common Pine-Apple. Many species are cultivated in the hot-houses of this country, the most beautiful of which belong to the genera *Bromelia* and *Billbergia*. They all grow readily in decayed tan. No species has been yet seen wild in any part of the Old World. The order contains 23 genera, and 170 species.

BROMUS, a genus of plants belonging to the natural order *Gramineæ*, and the tribe *Festuceæ*. It has unequal many-flowered herbaceous glumes, the lower being 1-nerved, the upper 3- to 5-nerved. The flowers are lanceolate, compressed. The outer palea short, (usually) founded on three nerves from below the tip. The styles below the summit of the fruit lateral. The sheaths of the leaves divided half way down.

The species are generally known under the name of Brome-Grass. Four of the species are common in Great Britain.

B. erectus has an erect stem two or three feet high, and grows on dry sandy and chalky soils. It is known from the other species by the outer palea being indistinctly 7-nerved and one-third longer than the smaller glume.

B. asper has its outer palea hairy and 5- to 7-ribbed, with the leaves broad and hairy. The stem reaches a height of four or five feet. It grows in damp woods and thickets.

B sterilis is a common plant in waste places, and is known by its outer palea having 7 distinct equidistant ribs. It has large flat broad pubescent leaves, and a stem from one to two feet high. It grows in waste places.

B. diandrus is remarkable for its erect panicle. It is a rare plant.

Some of the species, as *B. purgans* and *B. catharticus*, are purgative, whilst *B. mollis* is said to possess poisonous properties.

(Babington, *Manual of British Botany;* Lindley, *Vegetable Kingdom.*)

BRONGNIARTIN. [GLAUBERITE.]

BRONZITE, a native Silicate of Magnesia. It occurs in massive aggregations of columnar crystals. The cleavage is parallel to the lateral planes and both diagonals of a rhombic prism. Colour brown, ash-gray, or dark-green, streak lighter; fracture uneven; hardness between 4·0 and 5·0. The lustre is vitreous, pseudo-metallic on the cleavage-planes; translucent in thin laminæ; opaque in mass. Specific gravity 3·3. It is found in Upper Styria, the Harz, in Bayreuth, the Tyrol, and the Lizard district of Cornwall.

BROOK-BEAN. [MENYANTHES.]

BROOKITE, a native Oxide of Titanium. It is met with in thin hair-brown crystals attached by one edge. Its hardness is 5·5 to 6. Its crystals are secondaries to a rhombic prism. It is found in Dauphiny, and on Snowdon in Wales. It is also said to occur in the United States of America.

BROOM. [CYTISUS.]

BROOM-RAPE. [OROBANCHE.]

BRORA COAL. Beds of very poor Coal, lying in the midst of the Oolitic deposits in the district of Brora in North Scotland, and near Scarborough in Yorkshire, are thus termed. This Coal has been conjectured to be composed principally of *Equiseta*.

BRO'SCUS, a genus of Coleopterous Insects, belonging to the section of the *Carabidæ*, called *Simplicimani* by Latreille. In Latreille's work, however, this genus retains the name of *Cephalotes* (given to it by Bonelli, from the circumstance of the species possessing an unusually large head), which has been expunged by many naturalists owing to its having been previously used to designate a genus in some other branch of Natural History.

The insects of this genus are remarkable for the almost total absence of the indented striæ on the elytra generally observed in the insects of the tribe to which they belong, and for the large and strong mandibles, the elongate form of the body, and the somewhat heart-shaped thorax, which is much attenuated posteriorly.

It has the following characters:—Palpi with all their joints of nearly equal thickness, the terminal joint of the maxillary palpi rather short and truncated; the antennæ, if extended backwards, reaching to the base of the thorax; mandibles unidentate internally; labrum entire; anterior tarsi of the males with the three basal joints dilated.

The species are generally found under stones, and often accompanied by fragments of numerous other insects devoured by them. When taken in the hand they will often pretend to be dead, extending their limbs stiffly, and it is then with difficulty they can be made to move.

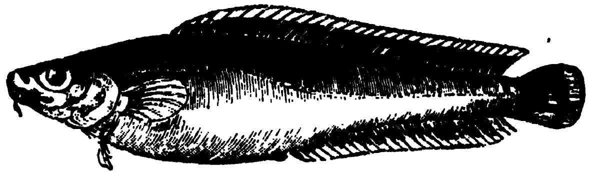
Only one species of this curious genus is a native of this country, *Broscus cephalotes*. It is of a dull-black colour, and varies from three-quarters to an inch in length: its form is elongate; the head is nearly equal to the thorax in bulk; the elytra are nearly smooth, the longitudinal striæ being scarcely discernible. It seems to be confined to the sea-coast, where it is frequently found under stones or rubbish.

In Stephens's arrangement of British Insects this genus is classed among the *Harpalidæ*. About six or seven exotic species have been discovered.

BRO'SIMUM, a genus of *Urticaceæ*, one species of which is believed to be the Cow-Tree, or Palo de Vacca of South America. [COW-TREE.]

BRO'SMIUS, a genus of Fishes belonging to the section Subbrachial *Malacopterygii*, and family *Gadidæ*. Generic characters:—Body elongate, and furnished with a single dorsal fin which extends from near the head to the tail; the anal fin is also of considerable length, and extends from the vent to the tail; ventral fins small and fleshy; chin furnished with but one barbule. This genus was established by Cuvier; it is the genus *Gadus* of Pennant ('British Zoology'), and *Brosmius* of Fleming ('British Animals').

But one species of *Brosmius* has been found on our coast, and that appears to be confined to the northern parts; it is the *B. vulgaris* of Cuvier, commonly called the Torsk, and in the Shetlands the Tusk and the Brismak; in this latter locality it is abundant, and forms when barrelled or dried a considerable article of commerce. In Yarrell's 'History of British Fishes' we are informed that this species also occurs plentifully in "Norway, as far as Finmark of the Faroe Islands, and the W. and S. coast of Iceland," and other parts.



The Torsk (*Brosmius vulgaris*).

The following is Pennant's description of this fish:—"Length twenty inches, and depth four and a half; head small; upper jaw a little longer than the lower; both jaws furnished with a multitude of small teeth; on the chin was a small single beard; from the head to the dorsal fin was a deep furrow; the dorsal fin began within six inches of the tip of the nose, and extended almost to the tail; pectoral fins small and rounded; ventral short, thick, and fleshy, ending in four cirrhi; the belly from the throat grows very prominent; anal fin long, and reached almost close to the tail, which is small and circular; colour of the head dusky; sides and back yellow, belly white; edges of the dorsal, anal, and caudal fins white, the other parts dusky; pectoral fins brown." When eaten fresh it is rather tough; hence it is preferred dried, and is prepared in the same manner as ling and cod. Faber says, "It is thrown up dead in incredible numbers on the coasts of the Faroe Islands, and the south coast of Iceland, after a storm." (Yarrell, *British Fishes.*)

BROSSÆA, a genus of plants belonging to the natural order *Ericaceæ*. The fruit of *B. coccinea*, like that of *Gaultheria procumbens* and *Arctostaphylos alpina*, is succulent and grateful to the taste, and sometimes used as food.

BRO'TULA, a genus of Fishes, of the order Subbrachial *Malacopterygii* and family *Gadidæ*, chiefly distinguished by the dorsal and anal fins being united with the caudal and forming one fin, which terminates in a point. This only species known (*B. barbatus* of Cuvier) is from the Antilles. The genus is closely allied to *Brosmius*.

BROUSSONE'TIA, a genus of plants belonging to the natural order *Urticaceæ* and sub-order *Moreæ*. There is but one species, *B. papyrifera*. It is from the inner bark of this plant that the Japanese and the Chinese manufacture a kind of paper, and the South Sea Islanders the principal part of their clothing. It forms a small tree with soft brittle woolly branches, and large hairy rough leaves, either heart-shaped and undivided, or cut into deep irregular lobes. Some of the individuals are sterile, others fruitful. The flowers of the sterile trees grow in catkins, which fall soon after their anthers have all shed their pollen; these catkins are composed of little greenish-purple membranous calyxes, each seated in the axil of a hairy bract and containing four elastic stamens. The flowers of the fruitful trees are collected into round green heads, and consist of a calyx like that of the sterile tree, with a small simple pistil occupying its centre, and having a long downy stigma. The heads gradually push forth little oblong greenish bodies; these are the ripening fruits, which at maturity have a bright scarlet colour, and are of a pulpy consistence, with a sweetish insipid taste.

B. papyrifera, the Paper Mulberry, is not uncommon in the shrubberies of this country, where it proves perfectly hardy; but it is liable to be broken by winds, and soon becomes an unsightly object. Its wood, like that of many other arborescent *Urticaceæ*, is soft, spongy, and of no value. In the tenacity of the woody tissue of its liber, or inner bark, it also corresp[illegible]with the general character of that order. It is from that part th[illegible]e preparations above alluded to have been obtained. Sir James Smith gives the following abridgment of Kæmpfer's account of the preparation of paper from its bark by the Japanese:—"For this purpose the branches of the present year, after the leaves are fallen, in December, are chosen, and being cut into pieces about a yard long are boiled till the bark shrinks and is easily separable from the wood, which is then thrown away. The bark being dried is preserved till it is wanted. In order to make paper it is soaked for three or four hours in water, after which the external skin and the green internal coat are scraped off; at the same time the stronger and firmer pieces are selected, the produce of the youngest shoots being of an inferior quality. If any very old portions present themselves they are, on the other hand, rejected as too coarse. All knotty parts and everything which might impair the beauty of the paper are also removed. The chosen bark is boiled in a lixivium till its downy fibres can be separated by a touch of the finger. The pulp so produced is then agitated in water till it resembles tufts of tow. If not sufficiently boiled the paper will be coarse though strong; if too much, it will be white indeed, but deficient in strength and solidity. Upon the various degrees and modes of washing the pulp much also depends as to the quality and beauty of the paper. Mucilage obtained from boiling rice, or from a root called *Oreni* (Kæmpf., 474), one of the mallow tribe, is afterwards added to the pulp. The paper is finished much after the European mode, except that stalks of rushes are used instead of brass wires."

BRU'CEA, a genus of plants, named in honour of James Bruce the celebrated traveller in Abyssinia, belonging to the natural order *Rutaceæ*. It has the following characters:—Flowers monœcious; calyx 4-parted; petals 4, hardly equal the length of the calyx; stamens 4, inserted round about a 4-lobed gland-like central body; the pistiliferous flowers with four abortive stamens; ovaries 4, seated on a 4-lobed receptacle, each terminated by a single, acute, reflexed stigma; fruit a drupe, 1-seeded. The species are shrubs, with unequally pinnated leaves, 6 pairs of opposite, entire, or serrated leaflets, without dots.

B. antidysenterica (*Brucea ferruginea* of L'Heritier), Woodginoos, has entire leaflets covered with rusty villi on the nerves beneath; racemes simple, spike-like. This plant is a native of Abyssinia, and is said to be a tonic and astringent, and to act favourably in dysentery. By some mistake it was at one time supposed to be the plant which yielded the false Angostura Bark of the shops. By the substitution of the False Angostura for the true Angostura Bark [GALIPÆA] fatal effects have been known to follow. At the time that the false Angostura Bark was supposed to be the produce of *Brucia ferruginea* an alkaloid was discovered in it which had been called on that account *Brucia*. It appears now however that there can be little doubt that the false Angostura Bark of the shops is a species of *Strychnos*. On this subject Dr. Christison, in the last edition of his 'Dispensatory,' has the following remarks:—"The Angostura Bark (*Galipæa Cusparia*) of this country is seldom adulterated; but on the continent a most serious fraud has been often practised by the substitution of a highly poisonous bark long erroneously conceived to be that of the *Brucea ferruginea* or *antidysenterica*. This bark, commonly called False Angostura, presents externally a dirty grayish-yellow ground with numerous irregular spots or tubercles of a lighter gray tint, which appearances are in the larger pieces displaced in patches, or entirely, by a uniform, loose, bright, rusty-coloured efflorescence. The speckled gray pieces alone bear some resemblance to the smaller pieces of true Angostura, but are easily distinguished by their greater thickness, their far more intense bitterness, without either aroma or pungency, and also, as the Edinburgh College has indicated, by the transverse fracture becoming bright red when touched with nitric acid. Another excellent character mentioned by the college, but applicable only where rusty specks exist, is, that such spots become deep bluish-green with the same acid; which, on the other hand, scarcely affects the true bark." Nitric acid does not similarly alter the spurious bark where it is quite free of rusty efflorescence. Fatal accidents from the substitution of the spurious for the true bark were at one time not uncommon on the Continent, and in Austria they were so frequent that upon one occasion the government ordered the whole Angostura Bark in the empire to be destroyed. This adulteration has never been publicly noticed in Britain, and experienced wholesale and retail dealers whom I have consulted both here and in London were unaware of its existence. A few weeks ago however Dr. Moore Neligan of Dublin informed me, that on inquiring for Angostura Bark at an extensive and respectable drug warehouse in that city he got the spurious bark, which proved to have been part of a considerable stock kept in the establishment since at least the beginning of this century, but never previously displaced. From specimens I owe to the kindness of Dr. Neligan there can be no doubt of the accuracy of his observation, so that druggists ought to be aware of the possible risk even in this country of so serious an error."

B. Sumatrana has serrated leaflets villous beneath, the racemes usually compound, the petals longer than the calyx. This plant is a native of Sumatra, the Moluccas, China, and Cochin-China. The leaves are intensely bitter, and possess the same medicinal properties as the former. (Christison, *Dispensatory*; Don, *Gardener's Dictionary*.)

BRU'CHUS, a genus of Coleopterous Insects of the section *Tetramera* and family *Rhynchophora*. It has the following characters:—Head slightly produced, and forming a short and broad rostrum; labrum distinct: antennæ 11-jointed, either filiform, serrated, or pectinated; eyes emarginated; thorax narrower before than behind, anteriorly rounded, posteriorly furnished with a lobe near the scutellum; elytra somewhat oblong, not reaching to the apex of the abdomen; femora of the hinder legs thick and generally dentated.

The female *Bruchi* deposit their eggs in the yet tender germ of various leguminous plants; the seed becoming matured is devoured by the larva, which lives entirely within the seed, where it undergoes its metamorphosis. The holes so often observed in peas and other seeds of a similar nature are those formed by the perfect insect to effect its escape; after which it is generally found in flowers.

From the habits of these insects as above related it may easily be conceived that when numerous they become exceedingly destructive. In Kirby and Spence's 'Introduction to British Entomology' we are told that in North America a species—*Bruchus Pisi*—is most alarmingly destructive to peas, "its ravages being at one time so universal as to put an end in some places to the cultivation of that favourite pulse." This insect is less than a quarter of an inch in length, of a blackish colour, and has a gray spot at the base of the thorax in the middle, and several spots of the same colour on the elytra, which are striated. The four basal joints of the antennæ and the anterior tibiæ and tarsi are red. The thorax has a little tooth on each side, and the femora are also dentate.

B. Pisi is a native of our own country (having most probably been introduced in the seeds of the pea), but fortunately it is not sufficiently abundant to do much mischief.

Two other species of *Bruchus* also infest the pea, *B. granarius* and *B. pectinicornis*: the latter is common in China and Barbary; the former is a native of this country, and is found among beans, vetches, and other seeds, the lobes of which it devours. It very much resembles *B. Pisi*, but is rather less.

The true *Bruchi* are generally of small size.

BRUCITE. [MAGNESIA.]

BRUGMA'NSIA. Two very different plants have been called by this name, one a Rhizanth belonging to the order *Rafflesiaceæ*, the other a plant belonging to the natural order *Solanaceæ*. The species of the latter are now referred to *Datura*. *D. arborea* is the Bovochevo of the Columbians, and is known in our gardens under the name of *Brugmansia*. Like the rest of the natural order *Solanaceæ* it is narcotic in a high degree. "This remarkable plant is a native of elevated and cold situations in the provinces of Tarma, Xauxa, Huarochesi, Canta, and Humalies, where it grows among rubbish; it is also found near the village of La Cruz and on the banks of the river Mayo, between Almaquer and Pasto in New Granada, where it was found by Humboldt and Bonpland at nearly 7000 feet above the sea. It begins to flower in June and ceases in November. By the Peruvians it is called Floripondio Encarnado and Campanillas Encarnadas; by the Columbians Bovochevo. Its stature varies from 10 to 12 feet, the stem being generally undivided and terminated by a roundish leafy head. The flowers are either a bright yellowish-orange colour or a deep orange-red: we believe they change from the former to the latter. They are succeeded by an oblong, smooth, yellow, pendulous capsule, which is as much as 8 inches long. The seeds, like those of the common *Stramonium*, are narcotic in a high degree. In the Temple of the Sun in the city of Sogamoza there is a famous oracle, the priests of which inspire themselves with the intoxicating seeds of this plant, just as the Pythoness at Delphi is said to have received the influence of her god by chewing laurel leaves and inhaling a gaseous vapour. From the fruit itself the Columbians prepare a drink called 'Tonga,' which when weak is merely soporific, but drank in stronger doses produces frenzy, which can only be removed by administering immediate draughts of cold water." ('Botanical Register.')

In cultivation it is hardy during the summer, but requires the protection of a greenhouse in winter.

BRUNI'ACEÆ, *Bruniads*, the Brunia Tribe, a small natural order of Exogens belonging to the albuminous group, and, notwithstanding the different habit, nearly allied to the currant tribe, *Grossulariaceæ*. The species are small heath-like shrubs, with minute closely-imbricated leaves, and small flowers collected in little compact heads. They have a superior 5-cleft calyx, 5 petals, 5 perigynous stamens, and a dicoccous or indehiscent 2- or 1-celled fruit, crowned by the persistent calyx. The seeds are solitary or in pairs, and have a short aril. All the species except one from Madagascar are natives of the Cape of Good Hope. They are of no known use.

Bruniaceæ differ from *Grossulariaceæ* in their dry fruit and central placenta; from *Escalloniaceæ* in the very small number of their seeds; from *Rhamnaceæ* in their minute embryo; and from both *Umbelliferæ* and *Araliaceæ* in their flowers not being in umbels. Their relations are with *Hamamelidaceæ*, *Myrtaceæ*, *Santalaceæ*, and *Umbelliferæ*. The order contains 15 genera and 65 species.

BRUNONIA'CEÆ, *Brunoniads*, the Brunonia Tribe, a natural order of plants belonging to the Monopetalous Exogens. This order was defined by Robert Brown, and has for its type a genus which was named after him. He placed it as a section of the natural order *Goodenoviæ*, but it is raised to the rank of an independent order by

Professor Lindley. It has an inferior calyx in 5 divisions, with four bracts at the base; a monopetalous corolla, almost regular 5-parted inferior withering; definite hypogynous stamens, alternate with the segments of the corolla; the anthers collateral, slightly cohering; a 1-celled ovary, with a single erect ovule; a single stigma inclosed in a 2-valved cup; a membranous fruit (a utricle) inclosed within the indurated tube of the calyx; a solitary erect seed without albumen; the embryo with plano-convex fleshy cotyledons, and a minute inferior radicle.

This order has but one genus, of which there are two species. They are herbs, natives of Australia, having flowers of an azure blue, which are on scapes, collected in heads, and surrounded by enlarged bracts. Although placed by Brown in *Goodenoviæ*, Lindley thinks it differs essentially from that order "in the superior 1-celled ovary and capitate flowers, thus approaching some species of *Dipsaceæ*, but differing in the want of an involucel, the erect ovule, superior ovary, and peculiar stigma." It agrees with *Compositæ* in inflorescence, in the æstivation of the corolla, in the remarkable joint or change of texture in the apex of its filaments, and in the structure of the ovarium and seed. Brown remarks, that "in the opposite parietes of the ovarium of *Brunonia* two nerves or vascular cords are observable, which are continued into the style, where they become approximated and parallel. This structure, so nearly resembling that of *Compositæ*, seems to strengthen the analogical argument in favour of the hypothesis advanced in the present paper of the compound nature of the pistillum in that order, and of its type in phænogamous plants generally; *Brunonia* having an obvious and near affinity to *Goodenoviæ*, in the greater part of whose genera the ovarium has actually two cells, with one or an indefinite number of ovula in each; while in a few genera of the same order, as *Dampiera*, *Diaspasis*, and certain species of *Scævola*, it is equally reduced to one cell and a single ovulum." There is but the genus, *Brunonia*, with two species, in this order. (R. Brown, *Linn. Trans.*, xii. 132; Lindley, *Vegetable Kingdom*, 266.)

BRYA'CEÆ, a name given to a section of the natural order of Mosses. [MUSCI.]

BRYA'XIS, a genus of Coleopterous Insects belonging to the family *Pselaphidæ*, which by some authors is arranged with the *Brachelytra*, but according to Latreille forms the third family of the section *Trimera*. Technical Characters:—Antennæ long, from the third to the terminal joint gradually increasing in size, the three terminal joints forming a large knob; the last joint much larger than the rest, and somewhat conical in shape; the two basal joints large; maxillary palpi distinct; the apical joints robust; head rather large; thorax rounded at the sides; elytra very broad, and covering only the basal half of the abdomen.

The species of this and allied genera, though minute, are perhaps among the most remarkable of the *Coleoptera*. In the short wing-cases they appear to evince an affinity to the *Brachelytra*, but in the number of joints in the tarsi, a character generally considered of importance, they differ; they likewise differ from that tribe in having the terminal joints of the antennæ immensely large, and in many other characters. They are generally found during the winter and early part of the spring in moss. Nine or ten species have been recorded as British.

BRYO'NIA. The Wild Bryony or Red Bryony of our hedges, *Bryonia dioica*, is a plant formerly much employed in rural pharmacy, but now disused. It is a perennial with large fusiform succulent roots, which have a repulsive nauseous odour. From these there annually springs a slender pale-green hairy branching stem, which climbs among bushes by means of its tendrils, in the manner of a cucumber, to which it is botanically allied, both belonging to the natural order *Cucurbitaceæ*. The leaves are palmate, and rough on both sides, with callous points. The stamens and pistils are on different flowers on different plants. The flowers in which the stamens are situated are larger than those which contain the pistils. They are whitish with pale-green veins, and the pistiliferous flowers are succeeded by little red berries containing a very few seeds. Its principal use was on account of the powerful drastic properties of its root, which the French call from that circumstance Navet du Diable, or Devil's Turnip. It is excessively bitter, and when dried purges in doses of 30 or 40 grains. Over-doses are extremely dangerous, and even sometimes fatal. Its properties are apparently owing to the presence of a principle called bryonine, analogous to cathartine, which exists in about the proportion of 2 per cent. of the root. It should be gathered in the autumn, after the stem has turned yellow; it is cut into slices, which are strung upon a thread, and hung in the air to dry.

BRYONY, BLACK. [TAMUS.]

BRYONY, RED. [BRYONIA.]

BRYOPHY'LLUM, a genus of succulent plants belonging to the natural order *Crassulaceæ*, and remarkable for the singular property possessed by its leaves of budding from their margin. These leaves are of a succulent texture, and sometimes pinnated; they or their leaflets are of an oblong figure, with a deeply-crenelled border; when placed in a damp and shady warm place they sprout from the crenels and form young plants—a property unknown in the same degree in any other vegetable production. Physiologists however consider that traces of a similar power, exercised in another way, exist in all plants in their carpellary leaves, from whose edges, forming placentæ, ovules, which are theoretically young buds, are constantly produced.

The only species is *Bryo[illegible]lum calycinum*, a shrub found in the Moluccas, with panicles of large pendulous greenish-yellow flowers. In this country it is a green-house plant; but is apt to be eaten by mice.

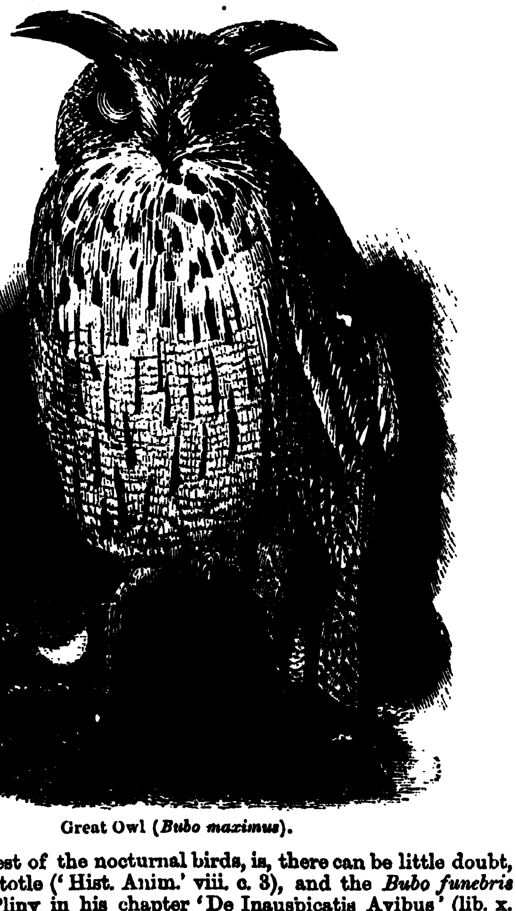
BRYOZOA, a name proposed by Ehrenberg for those Zoophytes in which a higher organisation is indicated by the presence of separate orifices for the mouth and anus. The same naturalist has applied the term *Anthozoa* to those Polypes in which the mouth and vent have but one orifice. The distinction between these two great families seems to have been observed by Mr. J. V. Thompson previously to the publication of Ehrenberg's name, hence his designation for this family, *Polyzoa*, is more generally received. Other names have been given to this interesting family of Zoophytes. Professor Owen calls them Molluscan Zoophytes, on account of their structure being supposed to ally them to the *Mollusca*. For the same reason they have also been called Ascidioid Polypes (*P. Ascidioida*). Milne-Edwards has also called them Tunicated Polypes (*Polypes tuniciens*). Dr. Farre in a paper in the 'Philosophical Transactions,' 1837, proposes to call them *Ciliobrachiata*, in reference to the ciliated character of their tentacula. Mr. Busk in his Catalogue of the Zoophytes in the collection of the British Museum, adopts Mr. Thompson's designation of *Polyzoa* as prior to that of any others. [POLYZOA.]

BRYUM, a genus of plants belonging to the natural order of Mosses. It has a terminal footstalk; double peristome, outer one of 16 teeth, inner one of a membrane cut into 16 equal segments with filiform processes often placed between them; the calyptra dimidiate. The species of this genus are exceedingly numerous. They are found in great abundance in Great Britain. They are all very small, produce a large number of capsules, and are found growing in wet places. They resemble forests of larger plants in miniature. In *B. palustre* are found terminal capitular bodies which resemble what are called the anthers of *B. Androgynum*; but in *B. palustre* they are considered gemmæ, and arise not only from the main stems, but also from the innovations. A large number of the species is British. [MUSCI.]

(Loudon, *Encyclopædia of Plants.*)

BUBO, a genus of Birds belonging to the family *Strigidæ*, separated by Cuvier, and characterised by a small concha, or ear aperture, and a facial disk, less perfect than in the sub-genus *Syrnium* (Chats-Huans of the French). Two tufts or feathered horns of considerable size adorn the head, and the legs are feathered down to the toes.

B. maximus, the Great Owl or Eagle-Owl; *Strix Bubo* of Linnæus; Le Hibou Grand Duc of the French; Gufo, Gufo Grande, and Gufo Reale of the Italians; Uhu, Grosse Ohreule of the Germans; Uff of the 'Fauna Suecica;' Buhu of the Lower Austrians.



Great Owl (*Bubo maximus*).

This, the largest of the nocturnal birds, is, there can be little doubt, the *Βύας* of Aristotle ('Hist. Anim.' viii. c. 3), and the *Bubo funebris* mentioned by Pliny in his chapter 'De Inauspicatis Avibus' (lib. x. c. 12 and 13), on account of whose advent Rome twice underwent lustration. Upon one of these occasions the bird of ill omen penetrated into the very cells of the Capitol.

Temminck says that it inhabits great forests, and that it is very common in Hungary, Russia, Germany, and Switzerland, less common in France and England, and never seen in Holland. He adds, that it is found at the Cape of Good Hope. Willughby observes that about Bologna, and elsewhere in Italy, it is frequent. Bonaparte notes it as rare in the neighbourhood of Rome, and says that it is only seen in mountainous situations. It is said to extend eastward as far as Kamtchatka.

Pennant states that it has been shot in Scotland, and in Yorkshire, from which county it was sent to Willughby. Latham adds Kent and Sussex as localities where it has been found. It is said to have been seen in the Orkneys; and four are stated to have occurred on the northern coast of Donegal in Ireland. The Eagle-Owl then can be only considered as a rare visitant to our islands.

The following is Temminck's description:—Upper part of the body variegated and undulated with black and ochreous; lower parts ochreous, with longitudinal black dashes; throat white; feet covered to the nails with plumes of a reddish-yellow; iris bright orange. Length two feet. The female is larger than the male; but the tints of her plumage are less bright, and she is without the white on the throat. It sometimes varies in having the colours less lively and in being of inferior dimensions.

Its food consists of young roes and fawns, hares, moles, rats, mice, winged game, frogs, lizards, and beetles.

It builds its nest in the hollows of rocks, in old castles and other ruins, where the female lays two or three, but rarely four, round white eggs. Latham says two, "the size of those of a hen."

M. Cronstedt, who resided on a farm in Sudermania, near a mountain, had an opportunity of witnessing the devotion of these birds to their young, and their care in supplying them with food, even under extraordinary circumstances. Two Eagle-Owls had built their nest on the mountain, and a young one which had wandered away was taken by the servants and confined in a hen-coop. The next morning there was a dead partridge lying close to the door of the coop. Food was brought to the same place for fourteen successive nights; this generally consisted of young partridges newly killed, but sometimes a little tainted. Once a moor-fowl was brought still warm under the wings, and at another time a piece of lamb in a putrid state. M. Cronstedt sat up with his servant many nights in order to observe the deposit of the supply if possible, but in vain. It was evident however to M. Cronstedt that the parents were the caterers, and on the look-out, for on the very night when M. Cronstedt and his servant ceased to watch, the usual food was left near the coop. The supply continued from the time when the young owl was taken—in July—to the usual time, in the month of August, when these birds leave their young to their own exertions.

Belon gives an account of the use which falconers made of this bird to entrap the kite. They tied the tail of a fox to the Eagle-Owl, and let him fly. This spectacle soon excited the attention of the kite, if he were near, and he continued to fly near the owl, not endeavouring to hurt him, but apparently intent on observing his odd figure. While so employed the falconer surprised and took the kite.

There are specimens in the Gardens of the Zoological Society in the Regent's Park.

Bubo Virginianus, the Virginian Horned-Owl (*Strix Virginiana* of Vieillott; Duc de Virginie of Buffon; Netowky-Omeesew of the Cree Indians, according to Mr. Hutchins; Otowack-Oho of the Crees of the plains of the Saskatchewan, according to Sir John Richardson).

Pennant, in his 'Arctic Zoology,' says that this seems to be a variety of the eagle-owl, although he notices the inferiority in size: but it is a very distinct species.

It is not improbable, as Sir John Richardson observes, that this night-bird, peculiar to America, inhabits that continent from end to end. Cuvier gives his opinion that the *Strix Magellanica* of the 'Planches Enluminées' differs merely in having browner tints of colour; and Sir John Richardson mentions the result of Mr. Swainson's comparison of the northern specimens with those of the table-land of Mexico, as confirmatory of the identity of the species; the only difference being a more general rufous and vivid tint of plumage in the Mexican specimens. Almost every part of the United States possesses this bird, and it is found, according to Richardson, in all the Fur Countries where the timber is of large size.

We have seen how the civilised Romans regarded the European bird; and it is curious to observe how, in a comparatively savage state, the same superstitious feelings were connected with the American species. "The savages," says Pennant, quoting Colden's 'Six Indian Nations,' "have their birds of ill-omen as well as the Romans. They have a most superstitious terror of the owl, which they carry so far as to be highly displeased at any one who mimics its hootings." Lawson, evidently speaking of these birds, says—"They make a fearful hallooing in the night-time, like a man, whereby they often make strangers lose their way in the woods." Wilson thus describes the haunts and habits of the Virginian Horned-Owl:—"His favourite residence is in the dark solitudes of deep swamps, covered with a growth of gigantic timber; and here, as soon as the evening draws on, and mankind retire to rest, he sends forth such sounds as seem scarcely to belong to this world. . . . . Along the mountain shores of the Ohio, and amidst the deep forests of Indiana, alone, and reposing in the woods, this ghostly watchman has frequently warned me of the approach of morning, and amused me with his singular exclamations, sometimes sweeping down and around my fire, uttering a loud and sudden 'Waugh O! Waugh O!' sufficient to have alarmed a whole garrison. He has other nocturnal solos, one of which very strikingly resembles the half-suppressed screams of a person suffocating or throttled." Wilson treats this visitation like a philosopher, but, after reading his description and that of Nuttall ('Ornithology of the United States'), we shall cease to wonder at the well-told tale in the 'Fauna Boreali-Americana,' of the winter night of agony endured by a party of Scottish Highlanders, who, according to Sir John Richardson, had made their bivouac in the recesses of a North American forest, and inadvertently fed their fire with a part of an Indian tomb which had been placed in the secluded spot. The startling notes of the Virginian Horned-Owl broke upon their ear, and they at once concluded that so unearthly a voice must be the moaning of the spirit of the departed, whose repose they supposed they had disturbed.

Virginian Horned-Owl (*Bubo Virginianus*).

The following is Sir John Richardson's description of the plumage of a specimen, 26 inches in length from the tip of the bill to the end of the tail, killed at Fort Chepewyan:—

"Bill and claws pale bluish-black. Irides bright yellow. Facial circle of a deep black immediately round the orbit, composed of white mixed with black bristly feathers at the base of the bill, and posteriorly of yellowish brown wiry feathers, tipped with black, and having black shafts. The black tips form a conspicuous border to the facial circle posteriorly; but the small feathers behind the auditory opening differ little in colour and appearance from the adjoining plumage of the neck. Egrets composed of ten or twelve dark brown feathers, spotted at the base of their outer webs, and along their whole inner ones, with yellowish brown. Forehead and crown dark blackish-brown, finely mottled with grayish-white, and partially exhibiting the yellowish-brown base of the plumage. The whole dorsal plumage is yellowish-brown for more than half the length of each feather from its base, and dark liver-brown upwards, finely barred and indented with undulated white lines. More of the yellowish-brown is visible on the neck and between the shoulders than elsewhere. The primaries present six or seven bars of dark umber or liver-brown, alternating with six bars, which on the outer webs are brownish-white, finely speckled with dark-brown, and on the inner webs are of a bright buff-colour, sparingly speckled with the dark-brown near the shafts. The tips of the feathers have the same mottled appearance with the paler bars of the outer webs. The secondaries and tail-feathers are similarly marked to the primaries, but show more white on their outer webs. There are six liver-brown bars on the tail, the last of which is nearly an inch from its end. Under-surface :—Chin white, succeeded by a belt extending from ear to ear of liver-brown feathers, having pale yellowish-brown margins. Behind the belt there is a gorget-shaped mark of pure white. The rest of the lower surface of the body is crossed by very regular transverse bars of white, alternating with bars of equal breadth (three lines) of liver-brown, shaded with chocolate-brown. The yellowish-brown base of the plumage is likewise partially visible : there is a white mesial line on the breast, and when the long feathers covering the abdomen are turned aside, a good deal of white appears about the vent. The outside thigh-feathers are yellowish-brown, with distant cross bars of liver-brown ; and the legs and feet are brownish-white with brown spots. The linings of the wings are white, with bars of liver-brown, margined by yellowish-brown. The insides of the primaries are bright buff, crossed by broad bars of clove-brown. On the under surface of the secondaries the clove-brown bars are much narrower. The under tail-coverts are whitish, with distant bars of liver-brown. The under surface of the tail has a slight tinge of buff-colour, and is crossed by mottled bars of clove-brown."

The bird preys, according to Richardson, on the American hare, Hudson's Bay squirrel, mice, wood-grouse, &c., and builds its nest of sticks on the top of a lofty tree, hatching in March. The young, two or three in number, are generally fully fledged in June. The eggs are white.

Wilson observes that it has been known to prowl about the farm-house and carry off chickens from roost. "A very large one," says that author, "wing-broken, while on a foraging excursion of this kind, was kept about the house for several days, and at length disappeared, no one knew how. Almost every day after this, hens and chickens also disappeared, one by one, in an unaccountable manner, till in eight or ten days very few were left remaining. The fox, the minx, and weasel were alternately the reputed authors of this mischief, until one morning the old lady herself rising before day to bake, in passing towards the oven surprised her late prisoner regaling himself on the body of a newly-killed hen ! The thief instantly made for his hole under the house, from which the enraged matron soon dislodged him with the brush-handle, and without mercy dispatched him. In this snug retreat were found the greater part of the feathers, and many large fragments of her whole family of chickens."

There are specimens in the Gardens of the Zoological Society in the Regent's Park.

BUBON. [GALBANUM.]

BUCCINUM, the name of a genus of Molluscous animals, to which the common Whelk belongs. Forbes and Hanley place it amongst the Prosobranchiate *Gasteropoda*, and the tribe *Muricidæ*. The following are its characters :—Shell ovate, more or less ventricose, turreted ; surface smooth or spirally striated, spirally grooved or longitudinally plicated, invested with an epidermis. Aperture ovate, emarginate, or very shortly canaliculated below ; canal wide, truncated dorsally, more or less tumid ; columella smooth, inner lip expanded, outer lip usually thin and smooth within. Operculum corneous, oblong, its nucleus lateral. Animal bulky ; head broad, depressed, bearing two somewhat flattened tentacula set well apart, their tips subulate, their bases thickened for half their lengths by the connate sustentacula, which bear the rather small eyes ; proboscis ample ; tongue armed with teeth, ranged three in a row, the axil one broad and quadrate, with many crenations, the laterals scythe-shaped, with denticulated bases. Male organ very large, sickle-shaped.

Messrs. Forbes and Hanley say—"We retain the old name *Buccinum* originally applied to whelks in general, for that group of shells of which the common *Buccinum undatum* may be regarded as the type. They constitute a very natural assemblage, though one of no great extent, and are mainly inhabitants of the boreal and arctic regions of both northern and southern hemispheres. The relation of the distribution of this form of mollusk to climate is strikingly shown when we compare such a shell as the *Buccinum cyaneum* of Greenland with the *Buccinum antarcticum* of the Falkland Islands, one of the most striking instances that can be cited of the representation of species by similar species in regions far apart, but subject to similar physical conditions.

"Several zoologists have of late united the *Buccinum undatum* and its allies with *Fusus antiquus* and similar shells, under the old generic name of *Tritonium*, originally proposed by Otho Frederic Müller. Independent of the very serious objection which applied to this name on account of its having become obsolete, whilst the too similar word *Triton* and even *Tritonium* itself were used in the meantime for a very different assemblage of *Muricidæ*, and one presenting good natural marks of distinction, we are inclined still, provisionally at least, to keep up the distinction between the *Fusi* of the north and *Buccinum*, since shell, animal, and operculum present marks of distinction, which, though in the end they may prove to be of no more than sectional value, yet in the present state of our knowledge deserve to be considered of importance. Unfortunately, the name *Buccinum* has even of very late years been applied to such a heterogeneous assemblage of shells, that it is difficult to disentangle those to which we restrict the names from a number of very different forms having no true generic affinity with them.

"These Mollusks appear to have commenced their existence during the later Tertiary epoch. At present they have the power of enduring very variable conditions of depth and locality, though the geographic range of the group is limited, however widely may extend the areas of some species."

B. undatum (Linnæus), the common Whelk. It has more or less coarse spiral striæ, and usually with broad longitudinal folds ; the beak short. Forbes and Hanley, amongst other synonyms for this very widely distributed species, give the following :—*B. striatum*, Pennant; *B. canaliculatum vulgare*, Da Costa ; *B. Borinanum*, Chemnitz ; *B. carinatum*, Turton ; *B. acuminatum*, Broderip ; *B. Anglicanum*, Fleming ; *B. Labradorense*, Reeve ; *B. imperiale*, Reeve ; *B. pyramidale*, Reeve ; *B. tenerum* (fossil), Sowerby ; *Tritonum undatum*, Müller ; *T. Humphreysianum*, Loven ; *Murex undatus*, Clark. As would be supposed from these synonyms, the Whelk is one of the most variable of shells. It is also one of the most widely distributed. It is found on almost every British shore, varying greatly however in its characters according to its locality. In most parts of the country it is used as an article of diet. Great numbers are to be seen exposed for sale in London. The process of cooking consists in simply boiling, and they are eaten with vinegar and pepper. They are not however very digestible. Dr. Johnston mentions that at the enthronisation feast of William Warham, archbishop of Canterbury, in 1504, no fewer than 8000 Whelks were supplied at five shillings for a thousand.

"This species," say the authors of the 'British Mollusca,' "first appeared in the British seas during the age of the coralline crag, and persisted through all succeeding epochs, becoming more and more abundant. It is found from low-water mark to as deep as one hundred fathoms. It has a wide latitudinal range, now extending throughout the Celtic, Boreal, and Icy Seas, and along the coast of Boreal America from Cape Cod to Greenland. According to Middendorff it finds its way through the Siberian seas into the Sea of Ochotsk. This great range in time and space accords with its capacity for variation and adaptation to circumstances. During the Pleistocene epoch it had found its way into the Mediterranean, and occurs fossil in the Sicilian newer Pliocene beds, but is now extinct in that region."

B. Dalei (Sowerby) has a polished white shell without folds ; the body half as long as the spine. It is the *Halia Flemingiana* of Macgillivray, the *Tritonium ovum* of Middendorff. The animal belonging to this shell is unknown. Messrs. Forbes and Hanley regard this shell as British, though exceedingly rare. It is an inhabitant of the Icy Seas, and ranges from Greenland to Behring's Strait.

B. Humphreysianum (Bennett). This species is faintly variegated, almost smooth, without folds, the body longer than the spine. The animal is unknown, and the shell is rare. It has been found on the British coasts, but like the last it appears to be an arctic species lingering in our Fauna.

B. fusiforme (Broderip) has an oblong subfusiform shape, is of a pure white, decussated by narrow longitudinal ribs and spiral costellæ ; the beak rather long, recurved. It has been found in Ireland in the neighbourhood of Cork and off the coast of Wexford. It is a very rare shell.

BUCCO. [BARBETS.]

BUCEROS. [HORNBILL.]

BUCHOLZITE, a mineral closely allied to Sillimanite. According to Thomson it is composed of—

Silica	46·4
Alumina	52·9

A specimen from Chester, Pennsylvania, gave Erdmann—

Silica	40·1
Alumina	58·9
Protoxide of Manganese	(a trace)

It is found at Fassa, in the Tyrol, and in several districts in the United States.

BUCIDA, a genus of plants belonging to the natural order *Combretaceæ*. One of the species, *B. Buceras*, yields a bark which is used in tanning.

BUCK. [CERVIDÆ.]

BUCK-BEAN. [MENYANTHES.]

BUCK'S-HORN. [RHUS.]

BUCK-THORN. [RHAMNUS.]

BUCK-WHEAT. [FAGOPYRUM.]

BUCKLANDIA, a fossil plant from the Stonesfield Oolite, supposed to belong to the natural order *Liliaceæ*.

BUCKLANDITE, a mineral containing silica, alumina, lime, protoxide of iron, protoxide of manganese, and water. It is a variety of Epidote, with iron. [EPIDOTE.]

BUCKU. [DIOSMA.]

BUD, or LEAF-BUD, in Vegetable Physiology, is the organised rudiment of a branch. Whatever becomes a branch is, when first organised, a bud ; but it does not therefore follow that all buds become branches ; on the contrary, owing to many disturbing causes, buds are subject to transformations and deformities which mask their real nature.

A Leaf-Bud is constructed thus :—In its centre it consists of a minute conical portion of delicate cellular tissue, and over the surface of this are arranged rudimentary leaves, in the form of scales. These scales are closely applied to each other ; those on the outside are the largest and thickest, and the most interior are the smallest and most delicate. In cold countries the external scales are often covered with hair, or a resinous varnish, or some other contrivance, which enables them to prevent the access of frost to the young and tender centre which they protect; but in warm countries, where such a provision is not required, they are green and smooth and much less numerous. The cellular centre of a bud is the seat of its vital activity; the scales that cover it are the parts towards the development of which its vital energies are first directed.

A Leaf-Bud usually originates in the axil of a leaf; indeed there are no leaves in the axil of which one or more buds are not found either in a rudimentary or a perfect state. Its cellular centre communicates with that of the woody centre of the stem, and its scales are in connection with the bark of the latter. When stems have the structure of Exogens, the bud terminates one of the medullary processes; in Endogens it is simply in communication with the cellular matter that lies between the bundles of woody tissue in such stems. It is moreover important to observe that this is true not only of what are called normal buds, that is to say, of buds which originate in the axil of the leafy organs, but also of adventitious buds, or such as are occasionally developed in unusual situations. It would seem as if, under favourable circumstances, buds may be formed wherever the cellular tissue is present; for they occur not only at the end of the medullary processes of the root and stem of Exogens, but on the margins of leaves, as in *Bryophyllum*, *Malaxis paludosa*, and many others; and occasionally on the surface of leaves, as in the case of an *Ornithogalum* published by Turpin, and not very commonly in ferns.

A Leaf-Bud has three special properties, those of growth, attraction, and propagation. In warm damp weather, under the influence of light, it has the power of increasing in size, of developing new parts, and so of growing into whatever body it may be eventually destined for. In effecting this it lengthens by the addition of new matter to its cellular extremity, and it increases in diameter partly by a lateral addition to the same kind of tissue, and partly by the deposit of woody matter emanating from the bases of the scales or leaves which clothe it. As soon as growth commences the sap which a bud contains is either expended in forming new tissue or lost by evaporation. In order to provide for such loss the bud attracts the sap from that part of the stem with which it is in communication; that part so acted upon attracts sap in its turn from the tissue next it, and so a general movement towards the buds is established as far as the roots, by which fresh sap is absorbed from the soil. Thus is caused the phenomenon of the flow of the sap. Every leaf-bud is in itself a complete body, consisting of a vital centre covered by nutritive organs or hairs. Although it is usually called into life while attached to its parent plant, yet it is capable of growing as a separate portion, and of producing a new individual in all respects the same as that from which it was divided; hence it is a propagating organ as much as a seed, although not of the same kind; and advantage has been taken of this for horticultural purposes. [BUDDING, in ARTS AND SC. DIV.]

In general a bud is developed into a branch, but that power is interfered with or destroyed by several causes. This must be evident from the following consideration independently of all others. Every one knows that leaves are arranged with great symmetry upon young branches; as buds are axillary to leaves, the branches they produce ought therefore to be as symmetrically arranged as leaves; and this we see does not happen. We may account for this in two or three ways: accidental injuries will doubtless destroy some; from want of light others will never be called into action; and of those which are originally excited to growth a part is always destroyed by the superior vigour of neighbouring buds, which attract away their food and starve them. There is moreover in many plants a special tendency to produce their leaf-buds in a stunted or altered state. In fir-trees the side-buds push forth only two or a small number of leaves, and never lengthen at all; in the Cedar of Lebanon they lengthen a little, bear a cluster of leaves at their points, and resemble short spurs; in the sloe, the whitethorn, and many other plants, they lengthen more, produce no leaves except at their very base, and grow into hard sharp-pointed spines. The knobs seen on beech and other trees, which have been called by Dutrochet embryo-buds and by Dr. Lankester abortive branches, take their origin in buds which are not normally developed. The bulbilli which are found in the axils of many Liliaceous plants originate in the bud. Bulbs are nothing but leaf-buds with unusually fleshy scales, and with the power of separating spontaneously from the mother-plant; and flower-buds are theoretically little more than leaf-buds without the power of lengthening, but with the organs that cover them in a special state. Hence flowers are modified branches. [FLOWER.] Schleiden regards the ovule as a changed bud; hence in his 'Principles of Scientific Botany' he calls this organ the seed-bud. [OVULE.]

BUDDLEA, a genus of plants named after Adam Buddle, a botanist of the time of Ray, who contributed to Ray's 'Synopsis,' and whose Herbarium is now in the British Museum. *Buddlea* belongs to the natural order *Scrophulariaceæ*. It has a campanulate 5-toothed calyx; tubular corolla with the limb 4-5-cleft, equal, spreading; 4-5 stamens nearly equal, inclosed, the anthers composed of two parallel distinct cells; the stigma clavate, 2-lobed; the capsule crustaceous with a dissepiment formed from the inflexed edges of the valves, inserted in the thick spongy placenta; the seeds angular; testa loose, membranous; albumen fleshy. The species are shrubs, with mostly quadrangular branches, opposite leaves; terminal, capitate, spicate or panicled, usually orange-coloured flowers.

B. globosa has branches clothed with hairy tomentum as well as the under sides of the leaves; the leaves lanceolate, acuminate, petiolate, crenate; the heads terminal, globose, pedunculate. This plant, now so common in our gardens, is a native of Chili.

B. Americana has branchlets clothed with hairy tomentum; leaves ovate, acuminate, narrow at the base, crenate, rather pilose above, but clothed with a yellowish tomentum beneath; spike panicled; flowers glomerate. It is a native of the mountains of Peru and also of the West Indies. Browne says that it is used in Jamaica as an emollient. Its properties however are not active.

There are about 60 species of *Buddlea*, all of which are worth cultivating on account of their showy blossoms. *B. Neemda*, a native of the peninsula of India, is said to be one of the most beautiful plants of that country. *B. globosa* will bear, with a little care, our winters as well as the *B. salvifolia*. All the flowers are sweet-scented. They grow best in a light rich soil. Cuttings will strike readily in mould under a hand-glass. Those of the stove species require heat.

(Loudon, *Encyclopædia of Plants;* G. Don, *Gardener's Dictionary*.)

BUFFALO. [BOVIDÆ.]

BUFFALO, AMERICAN. [BISON.]

BUFFO'NIA, a genus of plants named in honour of Buffon, the celebrated French writer on natural history. This genus belongs to the natural order *Caryophyllaceæ* and the sub-order *Alsineæ*. The calyx has 4 sepals; the petals are 4, entire; stamens 4; styles 2; capsules compressed, 1-celled, 2-valved, 2-seeded. The species are insignificant slender herbs, resembling the species of *Arenaria*. *B. annua* is a native of the south of France, and is said to have been found in England on the sea-coast of Lincolnshire.

BUFO, a genus of Reptiles belonging to the family *Bufonidæ*, and to which the Common Toad belongs. The genus is thus characterised:—Body inflated; skin warty; parotids porous; hind feet of moderate length, toes not webbed; jaws without teeth; nose rounded. About 20 species of this genus have been enumerated by naturalists. Two of them are found in the British Islands.

B. vulgaris, the Common Toad, is the *Rana Bufo* of Linnæus, the Crapaud Commun of the French. Its body is of a lurid brownish-gray colour, spotted over with reddish-brown tubercles: the body is much inflated. The Toad is very generally distributed over the British Islands, and from its dark colour, slow movements, and unprepossessing form, has acquired very general dislike. It is however perfectly harmless, and seems to possess an amount of intelligence that renders it capable of recognising those who treat it kindly. Mr. Bell in his 'British Reptiles' says:—"That toads may be rendered very tame, and be made to distinguish those who feed and are kind to them, there are abundant facts to testify. I have possessed a very large one which would sit on one of my hands and eat from the other; and the story of Mr. Arscott's toad in Devonshire, related in Pennant's 'British Zoology,' is too well known to need repetition." That they may be handled with impunity, and are incapable of producing any injurious influence, we know from having repeatedly seen them made the domestic pets of the children of a naturalist.

B. calamita, Natter-Jack, Walking Toad, Running Toad; *Bufo Rubeta* of Fleming, *Bufo mephitica* of Shaw, *Rana Rubeta* of Turton. It is known by its light yellowish-brown colour clouded with dull olive, but more especially by a bright yellow line along the middle of the back. It has acquired its name of Walking Toad or Running Toad in certain parts, from its never hopping, as is the case with the common toad and frog. Its colour varies very much according to circumstances, becoming lighter or darker in the course of a few minutes.

Pennant was the first to record this animal as British, and although very locally distributed it occurs in great numbers in some parts of Great Britain. Mr. Bell says it is common on Blackheath and at Deptford. It has also been found on Putney Common, at Gamlingay in Cambridgeshire, at Selbourne in Hampshire, and Bawdsey in Suffolk. It has also been found in Scotland. The form and appearance of this animal is less repulsive than the Common Toad. It is more social, and is generally found in communities. At Bawdsey they are found on the Red Crag cliffs overlooking the sea, and when alarmed hide themselves in holes in the sand which they make apparently for the purpose of concealment. The Natter-Jack appears to be an inhabitant of Ireland. Mr. Patterson in his 'Zoology for Schools' says:—"The Common Toad is there unknown, its absence being accounted for, according to popular tradition and song, by the malediction of St. Patrick. The smaller species, the Natter-Jack, does not appear however to have been banished with the rest of 'the varmint,' as it is found in three or four localities in the County Kerry and at Ross Bay, County Cork."

For an account of the general structure, habits, and classification of the family of Toads, see AMPHIBIA.

BUFONITES, the term commonly applied, previously to the investigations of M. Agassiz, to the roundish teeth of fishes frequent in the Oolitic Strata. They belong to the genera *Sphærodus*, *Gyrodus*, *Pycnodus*, &c.

BUG, one of a numerous tribe of Insects which constitute the order *Hemiptera*, belonging to the family *Cimicidæ* (Leach), and genus *Cimex*. The most common species is the *C. lectuarius*, the Bed-Bug.

It has been said that the Bed-Bug was not known in England previous to the great fire of London in 1666, and that it was first imported from America in the timber brought over to rebuild that city. Of the accuracy of this statement however there is considerable doubt. It appears to have been well known in various parts of Europe long before that time. Its shape, colour, and the offensive smell which it emits when touched, together with the circumstance of its deriving its nutriment from blood sucked through a long pointed proboscis, which when not in use lies parallel with the underside of the body, are circumstances too well known to need particular description. The female Bug deposits her eggs in the beginning of summer; they are of a tolerable size compared with that of the insect, of a whitish colour, and each fixed to a small hair-like stalk, which when the egg is first deposited is apparently of a glutinous nature, and readily adheres to anything which it touches. The places generally chosen in which to deposit the eggs are the crevices of bedsteads and other furniture, or the walls of a room. In about three weeks it is said these eggs hatch, and the young bug comes forth—an active larva, very closely resembling the parent insect except in size. The larva then undergoes the usual transformation, and becomes a perfect insect in about three months.

What was the natural habitat of this insect, which differs from most of its tribe in having no wings, is difficult to say. The species of bugs which come nearest to it in affinity are generally found under the bark of trees, a habitat which the flat form of our insect is well adapted for. Pigeons, swallows, &c., are attacked by bugs as well as man. Various means have been proposed for destroying these insects, but cleanliness is the best. [Cimicidæ.]

BUGLOSS. [Anchusa.]

BUGLOSS VIPERS. [Echium.]

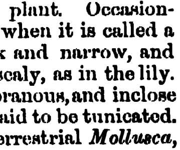
BUHRSTONE is a quartz rock containing cellules. It is as hard and as firm as a quartz crystal, and owes its peculiar value to this quality, and the cellules, which give it a very rough surface. Stones for grinding wheat and other kinds of grain are formed of this rock, and those which are most valued have the cavities about equal in space to the solid part. The best stones for this purpose come from France, and are obtained from the Paris basin and adjoining districts. When used for grinding, the stones are cut into wedge-shaped parallelopipeds, which are called panes. These are bound together by iron-hoops into millstones. The Paris Buhrstone is a Tertiary Formation. A Buhrstone is obtained in Ohio in America which is in part a true sandstone, and contains fossils. It also contains lime, and Mr. Dana suggests that the removal of the lime by solution may have given it its cellular character. It overlies the Coal Formation, and has an open cellular structure where quarried for millstones. The quartz rock of Washington in the United States is in some parts cellular, and makes good millstones. Buhrstone also occurs in Georgia near the Carolina line, and in Arkansas near the Cove of Wichitta. (Dana, *Manual of Mineralogy.*)

BUKKUM-WOOD. [Cæsalpinia.]

BULB, a bud, usually formed under ground, having very fleshy scales, and capable of separating from its parent plant. Occasionally it is produced upon the stem, as in some lilies, when it is called a bulbillus. [Bud.] Sometimes the scales are thick and narrow, and arranged separately in rows; the bulb is then called scaly, as in the lily. In the onion and leek the scales are broad and membranous, and inclose each other in a concentric manner; the bulb is then said to be tunicated.

BULI'MULUS, Leach's name for a genus of terrestrial *Mollusca*, which he thus defines:—Shell univalve, free, conically acuminated; spire elevated, regular; the last whorl very large; mouth entire, long; pillar smooth, simple; external lip thin; internal lip inflected towards the middle, with a hollow beneath. To this generic character the Rev. Lansdown Guilding observes that there should be the following addition: "Tentacula 4, the two upper ones long, with terminal eyes: no operculum." The last-named author observes that it differs from *Bulimus* in the delicacy of its outer lip. It is indeed a *Bulimus* of Lamarck. The shell varies much in colour. [Bulimus.]

Leach observes that *Bulimulus trifasciatus* (*Bulimus Guadalupensis*, Brug.), a very common existing West Indian species, occurs imbedded in the same limestone which incloses the fossil human skeleton from the Grande Terre of Guadaloupe, now in the British Museum.

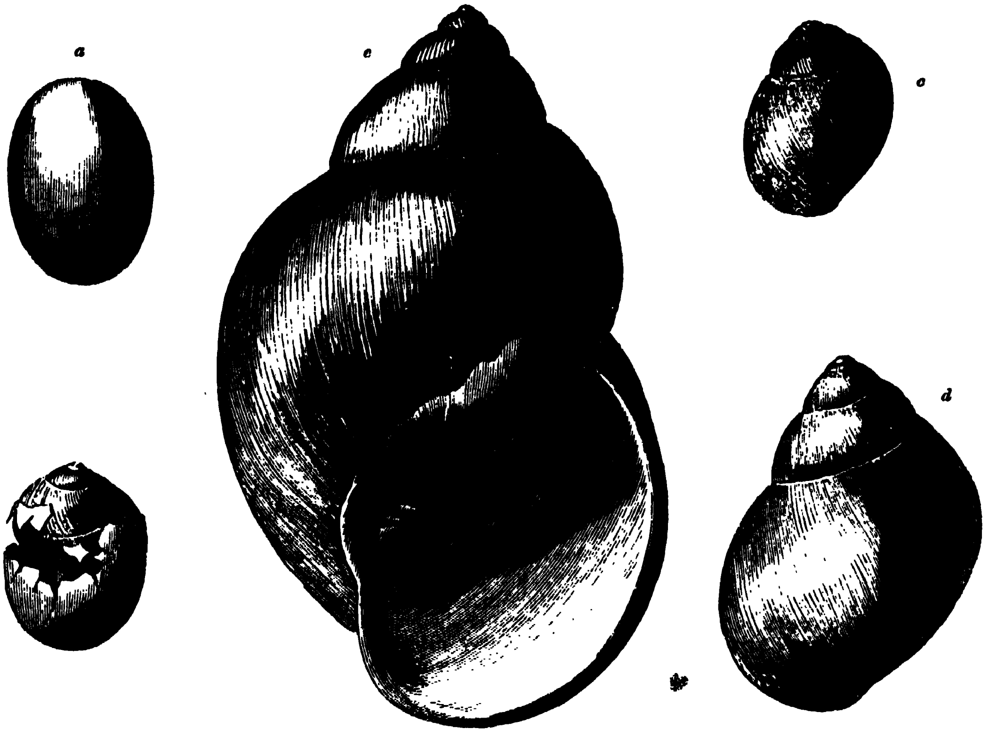


Bulimulus trifasciatus.

BULI'MUS, the name of a very extensive genus of terrestrial Pulmoniferous *Mollusca*. Lamarck arranges it under his Colimacés, a family of Phytophagous or Plant-Eating Tracholipods, respiring air by means of lungs, and protected by a spiral shell which is more or less elongated, oval, oblong, or turriculated, with an entire aperture longer than it is wide, and with a very unequal border, which is reflected in the adult. The columella is smooth, without any notch or truncation at the base, but with an inflexion in the middle at its point of junction with that part of the peristome which it contributes to form. De Blainville places it under the *Limacinea*, his third family of *Pulmobranchiata*, whose organs of respiration are retiform, and line the cavity situated obliquely from left to right upon the origin of the back of the animal, communicating with the ambient air by means of a small rounded orifice in the right side of the border of the mantle. Some of the species were placed by Linnæus under his genera *Bulla* and *Helix*. Scopoli and Bruguières began the reform, and Lamarck carried it still further. But before we proceed, it may be necessary to say a word as to the origin of the term used to designate the genus. "We constantly hear," says Broderip, in the 4th volume of the 'Zoological Journal,' "among conchologists the question, 'what is the meaning of Bulimus?' The author of the article entitled 'Lamarck's Genera of Shells,' in the 15th volume of the 'Journal of Science,' thus derives the word '*βοὐλιμος*—insatiable hunger: what title this genus has to so strange a name we know not.' It may not then be unacceptable to give a plain statement of the origin of the word. Swainson observes ('Zool. Illust.,' vol. i., '*Bulimus Melastomus*') that "the genus *Bulimus* was long ago formed by Scopoli, out of the heterogeneous mixture of shells thrown together in the Linnæan genus *Helix*." Let us now turn to Scopoli's account of the source whence he derived the name. "Proprium," says Scopoli, "itaque ex his constituo, et duce celeberrimo Adansonio Buli*m*os voco, ut eo facilius adgnoscantur. Solam testam nec animal inhabitans vidi, quod diversum esse à Limace affirmat Adansonius." ('Deliciæ,' &c., p. 67.) Now Adanson has no such genus as Buli*m*us, but he has such a genus as Buli*n*us. At plate 1, fig. G 2, in his 'Natural History of Senegal,' will be found 'Le Bulin, Bulinus,' but the letters 'n' and 'u' are so confusedly engraven, that at first sight the word looks like Buli*m*us. In the text (p. 5), the word is printed Buli*n*us very plainly; but neither Scopoli nor any of his successors appear to have noticed it. Till the time of Lamarck, who confined the genus (still calling it Buli*m*us, after Scopoli and Bruguières) to the land-shells with a reflected lip, which now range under it, many land and fresh-water shells which have not a reflected lip, such as *Achatinæ*, *Physæ*, *Limneæ*, and *Succineæ*, were also congregated under the name of Buli*m*us. The *Bulinus* of Adanson was a fresh-water shell, apparently a *Physa* or *Limnæa*."

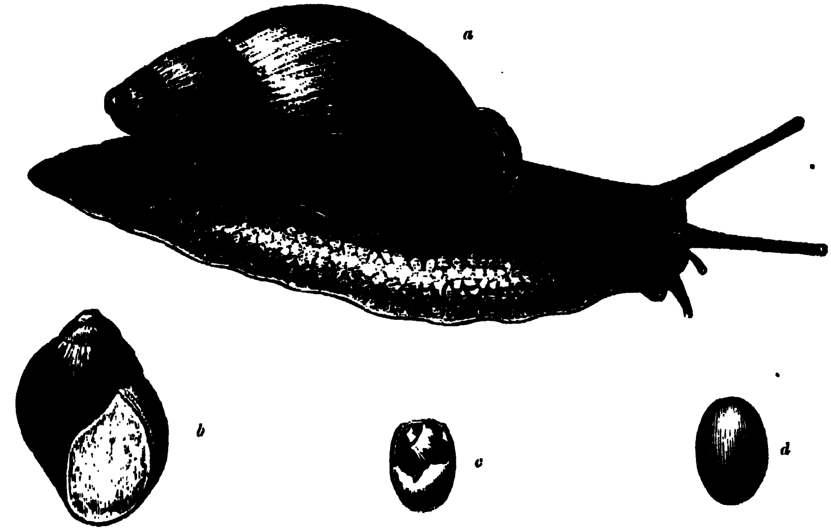
The shell is never orbicular, as in the *Helices*, but of the shape noticed at the commencement of the article. The last whorl is always larger than the penultimate, and indeed as a general rule may be stated to be larger than all the others put together. The mouth or opening is an oval oblong, and the border is disunited. The adult reflected lip or border on the right side is generally very thick, but this reflection is sometimes absent. The animal is very like that of *Helix*; De Blainville says entirely so—"toute-à-fait semblable." The head is furnished with four tentacula or horns, the two largest of which are terminated by the so-called eyes. There is no true operculum. The geographical distribution of the genus is very general, and there is scarcely a part of the world where the form does not occur. The great development of it takes place in the warmer climates, where some of the species are very large.

The species are multitudinous. Mr. Cuming has added largely to our knowledge of those of South America, and we are indebted to that gentleman for the following account of the habits of *Bulimus rosaceus*. In the dry season he always found the animals adhering to the under side of stones, generally among bushes, and close at the edge of the sea-shore, within reach of the spray at times. On the hills, about 1000 feet above the sea, they were observed adhering between the lower leaves of an aloe-like plant, on the honey of whose flowers the Giant Humming-Bird (*Trochilus gigas*) feeds. The natives burn down clumps of these plants for the sake of the rings at the bottom of the footstalks of the leaves, which they use for buoys for their fishing-nets and for baking the coarse earthenware which they make on the hills, because this part of the plant when ignited throws out a great heat. Between these leaves the *Bulimi* lie in the dry season in a torpid state. In the spring (the months of September and October) they burrow in the shady places at the roots of this plant, and among the bushes on the sea-shore. At this period (the spring) they lay their eggs in the earth, about two inches below the surface. Mr. Cuming never saw them crawling about. In the dry season they were evidently hybernating, for their parchment-like secretion, which operates in place of an operculum to seal up the animal, was strongly formed, and they stuck to the stones so tenaciously that Mr. Cuming broke many of them in endeavouring to pull them off. Chili and the neighbouring coasts of South America generally were the localities where the species was taken. Captain Phillip Parker King, R.N., has the following notice of the power of the animal to exist in a dormant state:—"Soon after the return of the expedition (his Majesty's ships Adventure and Beagle—'Survey,' 1826-30), my friend Mr. Broderip, to whose inspection Lieutenant Graves had submitted his collection, observing symptoms of life in some of the shells of this species, took means for reviving the inhabitants from their dormant state, and succeeded. After they had protruded their bodies, they were placed upon some green leaves (cabbage), which they fastened upon and ate greedily. These animals had been in this state for seventeen or eighteen months; and five months subsequently another was found alive in my collection, so that the last has been nearly two years dormant. These shells were sent to Mr. Loddige's nursery, where they lived for eight months in the palm-house, when they unfortunately died within a few days of each other. Soon after the shells were first deposited at Mr. Loddige's, one got away and escaped detection for several months, until it was at last discovered in a state of hybernation: it was removed to the place where the others were kept, when it died also. The upper surface of the animal, when in health, is variegated with ruddy spots and streaks on an ash-coloured ground." The only process used for revivifying these animals was placing them on a plate near a moderate fire, and sprinkling them with tepid water. Upon their restoration they eat a considerable part of the parchment-like seal or operculum. They lived some time with Mr. Broderip before they were sent to Messrs. Loddiges. These animals had been packed up in a box and enveloped in cotton from the time of their capture to the period mentioned, when they were unpacked by Mr. Broderip.



Bulimus hæmastoma, natural size.

a, The egg; *b*, the egg-shell broken, showing the young animal with its shell in situ; *c*, the shell of a young one just after exclusion from the egg; *d*, the shell at a more advanced age, but before the lip is reflected; *e*, the adult shells. The specimens figured were brought from Trinidad. It is found in the brakes of St. Vincent's and of the Antilles generally. The young shell is semitransparent, but becomes opaque as it advances in age. The adult shell is brown, strongly striated or wrinkled longitudinally, with a rose-coloured mouth. Epidermis brown.



Bulimus rosaceus, natural size.

a, an adult, with the animal as it is seen when in motion; *b*, a young shell before the lip is reflected. The mouth is represented as sealed with the parchment-like secretion, which serves as an operculum when the animal is hybernating; *c*, egg-shell broken, discovering the infant shell; *d*, egg, unbroken. Figure *a* was taken from one of the specimens mentioned above when living in this country. Adult shell roughish; apex and upper whorls of a rose colour in fine specimens; the other whorls brownish, mottled longitudinally in fine specimens with dirty white. Suture crenulated; lip white; throat brownish; epidermis greenish.

The British species of this genus are of small size and ordinary aspect. The following are enumerated by Forbes and Hanley in the 'British Mollusca.'

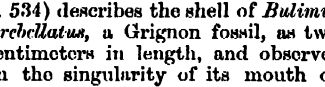
B. acutus is a small species, turreted, conical, white or clear brown, often with dark markings; body whorl comparatively short. It is most abundant near the sea, and is found in the Channel Islands, Dorsetshire, Devon, Cornwall, the Isle of Man, Scotland, and Ireland.

B. Lackhamensis is a rare shell in Great Britain. It is abundant in many districts of Germany, France, and Switzerland.

B. obscurus is of a yellowish-brown colour, with a smooth surface and mouth with white lips. The animal is of a dark colour. It is found under stones, on old walls and ruins, and on trees in woods, and is very widely distributed in the British Islands. Forbes and Hanley regard the following species as spurious in the British Fauna: — *B. Guadaloupensis*, *B. Goodalli*, *B. decollatus*, *B. pupa*, *B. Guildingii*, *B. ventricosus*. The distribution of the *Bulimi* has been treated in detail by Mr. L. Reeve.

Fossil Bulimi.

Deshayes, in his tables (Lyell's 'Principles of Geology,' 2nd edition) enumerates three fossil species of *Bulimi* in the Tertiary Formation, one of which is known to him from the sub-Apennine beds, and another from Paris; but he does not give the locality of the third, nor does he identify any of the fossils with recent species. De la Beche, in his 'Geological Manual,' under the head of 'Fossil Shells,' contained in the Supra-Cretaceous rocks of Bordeaux and Dax, enumerated by M. de Basterot, has the following notice: "*Bulimus* (?) *terebellatus*, Lam., analogous to the existing species, Grignon, Placentine, Dax." Lamarck ('Animaux sans Vertèbres,' vol. vii. p. 534) describes the shell of *Bulimus terebellatus*, a Grignon fossil, as two centimeters in length, and observes on the singularity of its mouth or opening, but he makes no allusion to its resemblance to any existing species. In the 'Annales du Muséum,' he places it among the *Bulimi*, with doubt, observing that it may from its conformation be probably marine, but keeping that generic name for it, because it approaches nearer to the *Bulimi* than to any other known genus. In the seventh volume of his 'Animaux sans Vertèbres,' published eighteen years afterwards, he still arranges it among the *Bulimi*, and not under the head of 'doubtful Species.' The fifteen species described by Lamarck in this volume are all stated to be fossil, and only the last five are separated as 'Espèces douteuses.' Of the not-doubtful species, *Bulimus sextonus*, found fossil at Villiers and Grignon, bears a great resemblance, according to the author, to *Bulimus lubricus*; but he observes that the opening or mouth of the fossil shell is much shorter than that of the recent, and that the summit of its spire is less obtuse. It may be doubted whether even the first ten fossil species enumerated by Lamarck are all true *Bulimi*.



Bulimus lubricus.

a, natural size; *b*, magnified. Inhabits Northern Europe, and is common in the neighbourhood of Paris. Shell smooth, shining, of a horn colour, inclining to fulvous; transparent.

De Blainville quotes Defrance for thirty-seven fossil species. [Helicidæ.]

BULL. [Bovidæ.]

BULLA. [Bullidæ.]

BULLACE, the English name of a kind of Plum, the *Prunus insititia* of botanists. It is probably a mere variety of the Sloe. [Prunus.]

BULLÆA. [Bullidæ.]

BULLFINCH, or BULFINCH, Latin *Pyrrhula*, French Bouvreuil, the name of a genus of Birds separated by Brisson from the Grosbeaks, afterwards again incorporated with them, and since by Temminck and others again arranged under Brisson's name *Pyrrhula.*

The following is Temminck's generic character:—

Beak short, hard, conico-convex, thick, swollen (bombé) on the sides, compressed at the point and towards the edge (arête) which advances upon the forehead; upper mandible always curved; lower mandible more or less so. Nostrils basal, lateral, rounded, most frequently hidden by the plumage of the forehead. Feet with the tarsus shorter than the middle toe; the front toes entirely divided. Wings short, the three first quills graduated (étagées), the fourth longest. Tail rather long, slightly rounded or squared.

The place generally assigned by ornithologists to the Bullfinches, between the Grosbeaks and the Crossbills, appears to be their proper position. Their food consists principally of seeds and kernels; and though the smaller species confine themselves for the most part to grain or seeds, which they open, rejecting the husk, some of the foreign species, as Temminck observes, have the bill excessively large and strong, and capable of fracturing the most ligneous seed-cases. Cold and temperate climates, adds the author last quoted, appear to produce the greatest number of species. They are found in Europe and America. The north of Asia appears to be equally their cradle, but they have never yet been observed in Australia, and but few have been noticed in Africa, while South America produces many. All the known species are subject to a double moult. The males and females differ, and can be easily distinguished in all stages of life. The young of the year differ but little from the old birds, and only till their autumnal moult.

Of the European species the Common Bullfinch may be taken as an example. It is Le Bouvreuil and Bouvreuil Commun of the French, according to Belon; Fringuello Marino, Ciufolotto, Suffuleno, and Monachino, of the Italians; Dom-Pape of the Danes and Norwegians; Dom-Herre of the 'Fauna Suecica;' Blutfinck, Rothbrustiger, and Der Gimpel of the Germans; De Goudvink of the Netherlands; *Loxia Pyrrhula* of Linnæus, and *Pyrrhula vulgaris* of Brisson. The provincial names are Norsk-Pipe, Coalhood, Hoop, Tony Hoop, Alp, and Hope.

Male.—Length about 6¾ inches, two inches and three-quarters being taken up by the tail, which is rather forked, and of a lustrous black, shot as it were with iron blue. Bill six lines in length, short, thick, and black. Shanks eight lines high, and black. Irides of a chestnut colour. Crown of the head, circle round the bill, and upper part of the throat, of the same hue with the tail. Nape, back, and shoulders deep gray, or rather bluish-gray. Cheeks, neck, breast, belly (to the centre of it), and flanks, red. Rump and vent white. Greater wing-coverts tipped and margined with a French or pinkish white, forming a transverse bar across the wing.

Bullfinch (*Pyrrhula vulgaris*), male.

Female.—Somewhat less than the male, and of a reddish-gray where he is red; back brownish-gray; feet brownish-black. The colours generally less bright than in the male.

The young of the year are at first ash-colour, with wings and tail of blackish-brown; afterwards more like the female till the autumnal moult; but the young males may always be known by the greater tinge of red about the breast.

There are several varieties:—

1. Black.—This variety may be produced artificially by feeding the bird entirely on hemp-seed, in which case a change of diet will often produce the true colours. Bechstein says it will arise from being kept when young in a totally dark place; and that females, either from age or from the diet above mentioned, are most subject to it.

2. White.—This is merely an albino of an ashy or dusky white, or cream-colour: the parts which are generally black are more shaded than the rest. There is a specimen from Middlesex in the British Museum.

3. Speckled or Variegated.—Spotted with black and white, or white and ash-colour, besides the natural hues. Selby says that Captain Mitford killed one, of which both the wings were white.

4. Bechstein mentions varieties under the name of the Large Bullfinch, about the size of a thrush, and the Middling or Common Bullfinch. He treats the dwarf variety, which is said to be not so large as a chaffinch, as a bird-catcher's story; for he observes that this difference of size occurs in all kinds of birds, and says he has had opportunities every year of seeing hundreds both wild and tame, and adds, that he has even found in the same nest some as small as redbreasts, and others as large as a crossbill.

The Bullfinch will produce hybrid young with the Canary.

The native song of this common but pretty bird is very soft and simple, but so low that it is almost inaudible. Its call is a plaintive whistle, and when feeding it utters a low short twitter. It has however acquired great celebrity from the facility with which it learns to whistle musical airs, and from its retentive memory, when well educated and carefully attended to. "Those which are to be taught," says Bechstein, "must be taken from the nest when the feathers of the tail begin to grow, and must be fed only on rape-seed soaked in water and mixed with white bread; eggs would kill them or make them blind. Their plumage is then of a dark ash-colour, with the wings and tail blackish-brown. The males may be known at first by their reddish breast; so that when these only are wished to be reared they may be chosen in the nest, for the females are not so beautiful, nor so easily taught, though they answer the purpose of call-birds as well as the male." Mrs. Charlotte Smith however says ('Nat. Hist. of Birds') that she had a nest of bullfinches given her, of which only one was reared: it was a hen, which she kept only because she had reared it, but the bird hung in the same room with a very fine Virginian nightingale, whose song she soon acquired, and went through the same notes in a lower and softer tone. "Although the young," continues Bechstein, "do not warble before they can feed themselves, one need not wait for this to begin their instruction, for it will succeed better, if one may say so, when infused with their food; since experience proves that they learn those airs more quickly and remember them better which they have been taught just after eating. It has been observed several times that these birds, like the parrots, are never more attentive than during digestion. Nine months of regular and continued instruction are necessary before the bird acquires what amateurs call firmness; for if one ceases before this time, they murder the air by suppressing or displacing the different parts, and they often forget it entirely at their first moulting. In general it is a good thing to separate them from the other birds, even after they are perfect, because, owing to their great quickness in learning, they would spoil the air entirely by introducing wrong passages; they must be helped to continue the song when they stop, and the lesson must always be repeated whilst they are moulting, otherwise they will become mere chatterers, which would be doubly vexatious after having had much trouble in teaching them."

A single air with a short prelude is generally as much as the bird can learn and remember; but Bechstein, who asserts this, allows that there are some of them which can whistle distinctly three different airs, without spoiling or confusing them in the least. In truth, as the same author observes, there are different degrees of capacity among the bullfinches as well as in other animals. One young bullfinch learns with ease and quickness, another with difficulty and slowly; the former will repeat without hesitation several parts of a song; the latter will hardly be able to whistle one after nine months' uninterrupted teaching. Those birds which learn with most difficulty are said to remember the songs, when once learnt, better and longer, and rarely forget them even when moulting. To these attractive qualities of the Bullfinch must be added its obedience and capability of strong attachment, which it shows by a variety of little endearing actions; and it has been known even to repeat words with an accent and tone indicative of sensibility, if, as Bechstein observes, one could believe that it understood them. Of its attachment the following are instances:—Buffon asserts that tame bullfinches have been known to escape from the aviary, and live at liberty in the woods for a whole year, and then to recollect the beloved voice of the person who had reared them, returning never more to leave her. Others, when forced to leave their master, are said to have died of grief. Buffon's story of the return of the escaped bullfinch is corroborated by the amiable qualities ascribed to it by Bechstein, for he says that, among other feats, it may be accustomed to go and return, provided the house is not too near a wood.

In a state of nature the Bullfinch feeds on pine and fir seeds, corn, linseed, millet, rape, and nettle seed, all sorts of berries, and the buds of most trees, among which those of the oak, beech, pear, plum, cherry, and gooseberry are favourites. Bewick says that in the spring it frequents gardens, where it is usefully busy in destroying the worms which are lodged in the buds. Busy it is; but we are compelled to add that its utility, to the horticulturist at least, is no longer questionable. In its devastation it may now and then, and no doubt does find a worm in a bud; but its object is the bud, not the worm. "They feed most willingly upon those buds of trees which break forth before, indeed are pregnant with, the leaves and flowers, especially those of the apple-tree, pear-tree, peach-tree, and other garden trees; and by that means bring no small detriment to the gardeners, who therefore hate and destroy them as a great pest of their gardens, intercepting their hopes of fruit." Such is Willughby's verdict. "I have known," says Selby, "a pair of these birds to strip a considerable-sized plum-tree of every bud in the space of two days. These buds are not swallowed whole, but first minutely divided by the tomia of the powerful bill." "Its delight," observes Mr. Knapp in his interesting and lively 'Journal of a Naturalist,' "is in the embryo blossoms wrapped up at this season (spring) in the bud of a tree; and it is very dainty and curious in its choice of this food, seldom feeding upon two kinds at the same time. It generally commences with the germs of our larger and most early gooseberry; and the bright red breasts of four or five cock birds, quietly feeding on the leafless bush, are a very pretty sight; but the consequences are ruinous to the crop. When the cherry buds begin to come forward, they quit the gooseberry, and make tremendous havoc with these. I have an early wall cherry, a may-duke by reputation, that has for years been a great favourite with the bullfinch family, and its celebrity seems to be communicated to each successive generation. It buds profusely, but is annually so stripped of its promise by these feathered rogues, that its kind might almost be doubted. The Orleans and green-gage plums next form a treat, and draw their attention from what remains of the cherry. Having banqueted here a while, they leave our gardens entirely, resorting to the fields and hedges, where the sloe-bush in April furnishes them with food."

Bewick says it builds its nest in bushes, and that it is composed chiefly of moss,—Bechstein, in the most retired part of a wood, or in a solitary quickset hedge, adding that it is constructed, with little skill, of twigs, which are covered with moss. Graves says that it is mostly found in the thickest part of a black- or white-thorn bush, and that it is composed of small twigs and moss, and is lined with soft dry fibres. Yarrell says the nest is formed of small twigs, and lined with fibrous roots, the materials not very compactly entwined together, and usually placed four or five feet above the ground on the branch of a fir-tree, or in a thick bush. The eggs are generally four or five; Temminck says from three to six, but in this country the number is usually four, of a bluish white, speckled and streaked with purplish or pale orange-brown at the large end, and rather obtuse. The young are generally hatched in May or the beginning of June, and there are frequently two broods in a year. The time of incubation is fifteen days.

The species is widely spread. They are common in most parts of Northern Europe, extending into Russia and Siberia: in the south of Europe they occur only as birds of passage. They are said to winter in Italy. Gesner says that about the Alps the bird is called Franguel Invernengk—that is, 'Winter Finch.' Bonaparte notes it as "raro d' inverno avventizio" near Rome. Thunberg long ago said that the common Bullfinch was found in Japan, and this is corroborated by Dr. de Siebold, for it was one of the European species which he found in that country. The bird is particularly common in the mountainous forests of Germany: and it is from Cologne and other spots,

"Where Rhenus strays his vines among,"

that the market for Piping-Bullfinches is principally supplied. Bechstein mentions that there are schools for these little musicians in Hesse and Fulda, and at Waltershausen near Gotha. With us the bullfinch is a constant resident.

P. Synoica, the Asiatic Bullfinch. The adult male is ornamented round the base of the bill with a circle of rich red, going off in spots upon the cheeks. The front is covered with small lustrous white feathers, of a silvery white, lightly shaded upon the borders with red; all the lower parts of the body, the inferior coverts of the tail, and the rump, are of a brilliant rose-colour, or clear carmine; the upper parts are ash-coloured, lightly tinged with rose: wings and tail brown, with ash-coloured borders.

The female is brown, of a light brown or earth-colour above, with longitudinal lines of deeper brown upon each feather. The lower parts are of a very clear brown or Isabella-colour, with longitudinal striæ of a somewhat deeper brown upon the middle of the feathers. The tail is slightly notched at the end, and the bill and feet in both sexes are of a clear brown. Length about 5 inches and 5-8ths. M. Hemprich found this species near Mount Sinai, in Arabia; and there are specimens in the museums of the Netherlands and of Berlin. Temminck, from whose work the figures and description are taken, thinks it possible that the 'social bullfinch' may be found some day in the islands of the Grecian Archipelago, and that it may easily pass in its migrations the arm of the sea between Asia and those isles.

Asiatic Bullfinch (*Pyrrhula Synoica*). Upper figure, male; lower figure, female.

Pyrrhula Gigathinca. Lower figure, male.

Temminck received his specimen from Professor Lichtenstein; and it was one of the discoveries of the travellers sent some years ago by the King of Prussia into Egypt with a view of obtaining objects of natural history.

A species from the Himalaya Mountains, *Pyrrhula erythrocephala*, figured in Mr. Gould's beautiful work, comes near to the common Bullfinch of Europe except in the form of the tail, which is decidedly forked, while in the European it is nearly even. There is a specimen of *Pyrrhula erythrocephala* in the British Museum, and another in that of the Zoological Society.

P. Gigathinea. This species is characterised by a very thick bill, and a slightly notched tail. The colours of the sexes do not vary greatly. In the male a grayish colour tinted with bright-rose covers all the lower parts of the body, the throat, and the circle round the bill; this tint is palest on the throat. The crown of the head is pure ash-colour, and an ashy brown is spread over the nape, the back, and the wing-coverts. A faint rose-colour tinges the plumage of the rump and the edges of the quills and tail-feathers, all of which are bordered towards the end with whitish upon a black ground. The two middle quills are the shortest. The wings reach to the extremity of the tail-feathers; the bill is of a fine red. Length 4 inches 6 lines.

The female has no rosy tint except on the edges of the quills and tail-feathers, and on the rump, where it is very faint. The upper parts are of an Isabella-brown, and the wings edged with a brighter tint of the same. The circle round the bill and the throat are ash-coloured; the lower parts of a pure Isabella-colour; and the middle of the belly white. Bill same as in the male.

This bird is figured in the great French work on Egypt (plate 5, fig. 8), and was sent home some years ago by the German travellers to the north of Africa. It inhabits Egypt and Nubia. There are specimens in the Berlin museum, and in those of the Netherlands and of Frankfort.

P. cinereola. Head, cheeks, back, and scapulars, ashy-bluish; wings and tail darker, but all the feathers of those parts are bordered with ash-colour. There is a small white spot on the wing, formed by the white towards the base of the quills, beginning with the fourth; the first three have no white. All the lower parts are white, with the exception of the flanks, which are clouded with ash-colour. Bill coral-red, very strong, large, and as it were swollen (bombé). Feet ash-coloured. Length 4¼ inches. Inhabits Brazil, where it is said to be common.

Pyrrhula cinereola.

BULLHEAD. [COTTUS.]

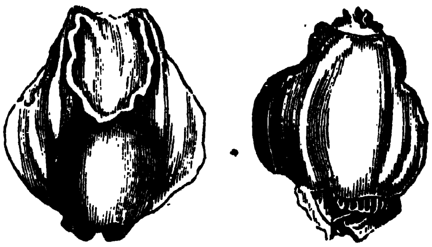
BULLHEAD, ARMED. [ASPIDOPHORUS.]

BU'LLIDÆ, a family of Marine *Mollusca*, which Lamarck arranges among his Gasteropods, between the Calyptracians on one side and the Laplysians on the other, making the family to consist of the three following genera, *Acera* or *Akera*, *Bullæa*, and *Bulla*. Cuvier finds a situation for it in his fourth order of Gasteropods, the Tectibranchians (Monopleurobranchians of De Blainville), which includes both *Aplysia* and *Umbrella*. De Blainville places it next but one to his Aplysians (his family *Patelloidea* intervening) under the family *Akera*, the fourth of his third order *Monopleurobranchiata*, of his second sub-class *Paracephalophora Monoica*, of his second class *Paracephalophora*.

Forbes and Hanley make it the first family of the *Gasteropoda opisthobranchiata*. They observe that "this tribe may be considered intermediate between the two great sections of *Gasteropoda*. The shells of its mollusks are always convolute and more or less enveloped by the animal; sometimes entirely invested, more rarely absent. Except in the case of *Tornatella* there is no operculum. The head of the animal is in the form of a single or lobed disk, and its lateral lobes are often greatly developed, so as in many species to serve as swimming organs. The foot is in some extremely small, in others a crawling disk of considerable dimensions. There are more than 150 species of this family known. They inhabit all parts of the world, and some of them are very widely diffused." The best account of the family that has yet appeared is by Mr. Arthur Adams in the 'Thesaurus Conchyliorum' of Mr. G. B. Sowerby, Jun.

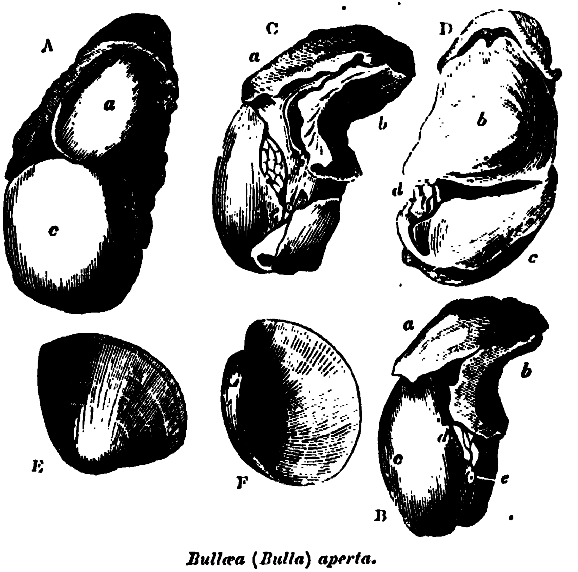
The following are illustrations of some of the genera:—

Acera, Lamarck, *Lobaria*, De Blainville, has its body oval-oblong, sub-globular, appearing to be divided into four parts: one anterior for the head and thorax, one on each side for the natatory appendages or fins, and one posterior for the viscera. The anterior fleshy disk terminates in an approach to a point near the middle of the body: the branchiæ covered by the mantle are so posterior that they seem to be almost at the extremity of the body, and below them would be the analogous situation for the shell, of which there is not even a rudimentary trace.



Lobaria carnosa, Cuv.

Bullæa. Lamarck assigned this name to those of the family which have the shell entirely hidden in the substance of the mantle. This shell is very open and delicate, and can hardly be said to have more than the first rudiment of the rolled-up form which is in *Bulla* carried to greater perfection. *Bullæa aperta*, Lam. (*Bullæa Planciana*, Lam., in the early edition of the 'Syst. des Anim. sans Vert.'); *Amygdala marina* (Amande de Mer), Planc.; *Bulla aperta*, Lin.; *Bulla aperta* and



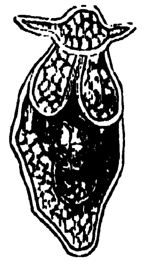
Bullæa (*Bulla*) *aperta.*

A, view of the back; B, side view, the right; C, the same, but the ventral fleshy plate separated from the dorsal to show the parts between; D, view of the under side; *a*, the fleshy plate which covers the anterior part of the body; *b*, the fleshy plate that acts as a foot; *c*, the part which contains the shell; *d*, a part of the branchiæ; *e*, the vent; *f*, the common orifice of the testicle and oviduct; E, shell in its natural position; F, view of the under or concave side.

Lobaria quadriloba, Gmelin, which is found in almost all seas, and is very common on the shores of Great Britain, will serve for an example. The animal is whitish, more than an inch in length, and, as Cuvier observes, the fleshy shield formed by the vestiges of the tentacula, the lateral borders of the foot, and the mantle occupied by the shell, seem to divide it into four portions, whence Gmelin's term *quadriloba*. The shell is delicate, white, semitransparent, and consists almost entirely of aperture. The stomach or gizzard is armed with three very thick rhomboidal bones or rather shelly pieces.

Bullæa has been found at a depth ranging from near the surface to 12 fathoms. Mr. W. Clark found three English species, two of them (*Bullæa catena* and *B. punctata*) at Exmouth and Torquay, in pools at the time of the lowest spring-tides; and a third (*Bullæa pruinosa*) by dredging off Budleigh Salterton. The depth is not mentioned, but it is probable that it was considerable, for the author says that it is rare, and only occasionally to be procured by deep dredging seven or eight miles from the shore. The first of Mr. Clark's species, which is *Bulla catena* of Montagu, had a testaceous gizzard, but the gizzards of the other two were unfurnished with shelly appendages. (See Mr. Clarke's description, 'Zool. Journ.' vol. iii. p. 337). G. Sowerby, when speaking of the use of the shelly species and their powerful adductor muscles, states that the animal of *Bullæa aperta* is sometimes distorted by having swallowed entire a *Corbula nucleus*, which is a very thick and strong shell, nearly equal in size to itself.

De Blainville says of this genus that he characterises it somewhat differently from Lamarck, who establishes it, and who only places under it the *Accrata*, whose shell is internal; but as De Blainville considers the animal to be of the first consequence, he distinguishes under the name of *Bullæa* those species which, whether their shell be external or internal, have the foot thickest and not dilated into natatory appendages, having, in fact, habits different from the *Bullæ*, according to his acceptation of the term, which swim very well and creep very badly. He divides *Bullæa* into—



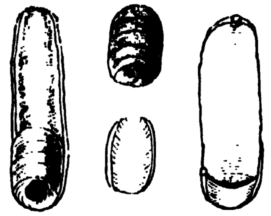
Ferussac's *Bullæa*.

1st. Those species which have an internal shell very incompletely rolled up without spire or columella, and selects as his eaxmple *Bullæa aperta*, the species figured in the preceding page.

2nd. Those species whose shell is internal and very incompletely rolled up, with a columella and alveolar spire (spire rentrée), and gives as an example *Bulla ampulla.*

3rd. Species whose shell is internal, the lateral lobes cirrhous and more developed, and gives as an example Ferussac's *Bullæa* (Quoy et Gaimard), here figured from the 'Atlas Zoologique' of the voyage of the Uranie.

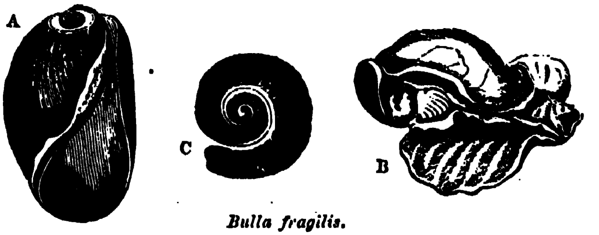
In the 'Additions and Corrections' to his 'Malacologie,' De Blainville says, that, in studying more attentively the species of these two genera, it seems to him that the greater part would be better placed under *Bulla* than under *Bullæa*, where he would leave only the species which serves for the type, and another which was brought from the seas of Australia by Quoy and Gaimard. He then proposes an entirely new arrangement into seven groups represented by the following genera:—1. *Bullina* (Bulline) of Ferussac, with a projecting spire (example *Bulla Lajonkairiana*, Bast.) 2. *Aplustre* (Schum.) 3. *Bulla.* 4. *Atys* (Montf.) 5. The form represented by *Bulla fragilis.* 6. *Scaphander* (Montf.), which is *Bulla lignaria.* 7. *Bullæa* (Lam.).



Sormetus Adansonii.

Sormetus. Cuvier observes that this form approaches very closely to that of his *Bullæa*, but he adds that he does not find sufficient certainty in the imperfect materials afforded by Adanson to enable him to found either a genus or even a species on them. De Blainville places it as a genus next to *Lobaria;* but his description and figure are taken from Adanson, and he is obliged to add that it is established upon an animal "assez incomplètement connu."

Bulla. Besides the true *Bullidæ*, the heterogeneous *Bulla* of Linnæus comprised some of the *Physæ* and *Achatinæ*, and of the *Ovula, Terebella, Pyrulæ*, &c.: in short, the genus comprised animals of entirely different organisation. Terrestrial and marine testacea—the former breathing air and the latter respiring water—were there placed side by side. Lamarck retains the name (and Cuvier seems to adopt his arrangement) for the species whose shell covered by a slight epidermis is sufficiently large to afford a retreat to the animal, and is more perfectly rolled up than the shell of *Bullæa.* Lamarck describes the shell of his *Bulla* as completely rolled up (enroulée), showing itself constantly uncovered. It is, generally speaking, only partially enveloped by the animal, which can retreat into it almost entirely; has no distinct columella nor any true spire, unless indeed that term be applicable to the apex of *Bulla fragilis*, which we now proceed to describe. Its shell is ovate-oblong, very thin and fragile, of a horn colour, with very small transverse striæ, and the apex rises into the rudiment of a projecting spire.

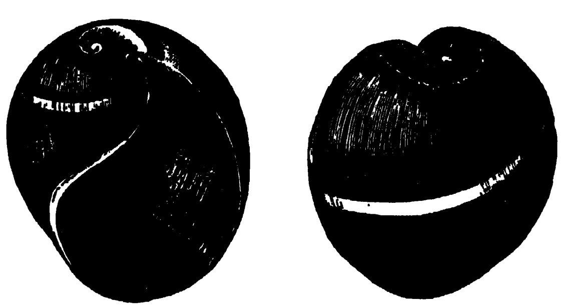


Bulla fragilis.

A, the shell showing the aperture; C, a view of the spiral end, showing the way in which the shell is rolled up; B, the animal.

It is the *Akera bullata* of O. F. Müller, and is not uncommon on the British coasts. We now proceed to give an example of those species which, while they have a little more solidity than *Bulla fragilis*, are still very delicate and fragile in their texture.

B. Velum. The shell is very delicate, of a very light horn-colour when in fine condition, with a snow-white band about the middle, bordered on each side with a broad dark-brown one; the apex and base are white, both bordered with dark brown bands.



Bulla Velum.

B. ampulla. The shell is ovate and subglobose, beautifully mottled with white, plum-colour, and reddish. Instead of a spire there is an umbilical alveolus. Lamarck gives as a locality both the Indian and American oceans; Deshayes, the European ocean and the Indies.

Bulla ampulla.

B. lignaria (*Scaphander lignarius*) is a common species on our coasts. It has a testaceous stomach or gizzard, so well known as the vehicle of Gioëni's half error, half fraud. He found these testaceous gizzards and elevated them immediately to the rank of shells 'sui generis' literally, for he gave the genus his own name, and imposed upon many: he went so far as to describe the habits of his pretended testaceous animal. Draparnaud first exposed this piece of charlatanerie.

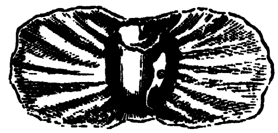
B. Hydates, Linnæus, and *B. Cranchii*, Leach, are found in the British seas. *B. media*, Philippi, *B. columna*, Chiaje, are recorded as British, but may be regarded as doubtful.

The following genera of *Bullidæ* are found in Great Britain:—*Cylichna*, eight species [CYLICHNA]; *Amphisphyra hyalina; Tornatella fasciata; Akera bullata; Bulla*, two species; *Scaphander lignarius; Philine*, six species.

Fossil Bullidæ.

Lamarck enumerates four fossil species, all of them from Grignon; G. Sowerby says that such are only to be distinguished in the Tertiary Beds and in the Greensand. Deshayes in his tables, speaking of tertiary fossils only, gives two fossil species of *Bullæa*, one from the sub-Apennine Beds, and one from Paris. Of *Bulla* he enumerates twenty-three fossil in the Tertiary Beds; and of these, two are both living and fossil, namely, *B. lignaria* and *B. ampulla.* The first he places in Sicily, in the sub-Apennine Beds (Italy), and the English Crag at Bordeaux and Dax, in Touraine, at Turin, Angers, Paris, and Valognes; in short, in the beds of the Pliocene, Miocene, and Eocene periods of Lyell. The second, Deshayes quotes as occurring in beds of the Pliocene period only, namely, those of Sicily and the sub-Apennine Beds (Italy). In his edition of Lamarck (vol. vii., 1836,) he takes no notice of *B. ampulla* as a fossil, but notices *B. striata* (which he observes has been confounded with *B. ampulla*) as a fossil species. He also remarks on the confusion between *B. solida* and *B. cylindrica*, and proposes that *B. solida* should take the name of *B. cylindrica;* that the *B. cylindrica* of Bruguières, living in the Mediterranean and European seas, should be called *B. cylindracea* (Pennant's name); and that the fossil *Bulla* from the environs of Paris, confounded with the latter, should be named *B. Bruguièrei*.

De Blainville places under his family of *Acerata*, the genus *Gasteroptera*, whose body is divided into two parts, the posterior being globular and joined by a peduncle to the anterior portion, which is small, but enlarged on each side into a considerable muscular expansion transversely oval, and cut or hollowed out in the middle, both above and below, rendering the expansion bilobated, as it were, and an organ for swimming, in place of a foot for creeping. The lateral gill is uncovered; there is no shell. Example, *G. Meckeli*, from the Sicilian seas.



Gasteroptera Meckeli.

BULLRUSH the English name of *Typha latifolia* and *T. angustifolia*, two wild marsh plants bearing long black cylindrical masses of flowers. The name is also sometimes applied to *Scirpus lacustris*, a tall rushy-looking plant from which the bottoms of chairs, mats, &c., are often manufactured. [TYPHA; SCIRPUS.]

BULLRUSHWORTS. [TYPHACEÆ.]

BULL-TROUT. [SALMO.]

BULLY or BULLET-TREE. [MIMUSOPS.]

BUMASTES, a genus of *Trilobites* thus named by Sir R. Murchison, includes the *B. Barriensis*, or Barr Trilobite, which occurs in the Upper Silurian Strata.

BUMELIA, a genus of plants belonging to the natural order *Sapotaceæ*. Many of the species are used in medicine. *B. nigra* has a bitter and astringent bark, which is used in fevers. The wood is very hard. *B. retusa* has a milky fruit. The fruit of *B. lycioides* is austere, with some sweetness, and is said to be useful in diarrhœa. The flowers of *B. graveolens* have a heavy unpleasant odour. (Lindley, *Vegetable Kingdom*.)

BU'NIUM, a genus of plants belonging to the natural order *Umbelliferæ*, the sub-order *Orthospermeæ*, and the tribe *Ammineæ*. It has an obsolete calyx; obcordate petals, with a broad obtuse inflexed point; an oblong fruit, the carpels with 5 filiform equal ridges; the interstices with 1 or 3 vittæ; the stylopodium conical. The species are perennial herbs with usually tuberose and globose roots, square stems, compound leaves, and white flowers.

B. flexuosum, the Pig-Nut, has a general involucre of 1-3 leaves, partial more numerous; fruit oval, narrowing upwards, crowned with the elongated stylopodium and erect styles, interstices with 3 vittæ. This species is the *B. denudatum* of De Candolle: it is a native of the west and south of Europe, and plentiful in Great Britain. It has a nearly globular root, of a black or chestnut colour on the outside and white inside. It has an aromatic sweet taste, and is frequently dug up and eaten by children. It is called in this country by many names, as Earth-Nut, Ar-Nut, Kipper-Nut, Hawk-Nut, Jur-Nut, Earth Chestnut, and Ground-Nut. The synonyms are almost as numerous in the French and German languages. Pigs are very fond of this nut, and get fat when they are allowed to feed on them. When boiled they are a pleasant and nutritious food. Roasted, they are preferred by some people to chestnuts, and are often in this country and on the Continent added to soup or broth.

B. Bulbocastanum of Linnæus is a different species from the latter, though often confounded with it. Its general and partial involucres are composed of numerous leaves, the fruit oblong, crowned with the short stylopodium and reflexed styles, the interstices with single vittæ. This plant has been discovered in chalky fields in Cambridgeshire and Herts, and is probably more generally diffused. George Don enumerates in the 'Gardener's Dictionary' sixteen species of *Bunium*. (Babington, *Manual of Brit. Bot.*)

BUNTER SANDSTEIN, the lowest arenaceous member of the Triassic system of strata, as understood in Germany (the lowest part of our Mesozoic Series). The three parts are—

Keuper above, marly.
Muschelkalk in middle, calcareous.
Bunter Sandstein below, arenaceous.

This classification is applicable to England by retrenching the middle term. Sir R. Murchison is of opinion that part of the Bunter Sandstein (Grès Bigarré of France) belongs to the Palæozoic Series, but no proof of this is yet published.

BUNTING is the common name applied to a number of small Birds belonging to the order *Insessores* and the family *Emberizidæ*. The Common Bunting, the Yellow Bunting, the Cirl Bunting, and the Ortolan Bunting, all British birds, are species of the genus *Emberiza* [EMBERIZA]; whilst the Snow Bunting and the Lapland Bunting, also British, are referred by Yarrell to the genus *Plectrophanes*. [PLECTROPHANES.]

BU'PALUS, a genus of Insects belonging to the order *Lepidoptera* and the family *Geometridæ*. It has the following characters:—Palpi very short; antennæ in the males pectinated on each side to the apex, in the females simple; wings erect during repose; the anterior wings in the males having a protuberance at the base; larva smooth, and furnished with ten legs.

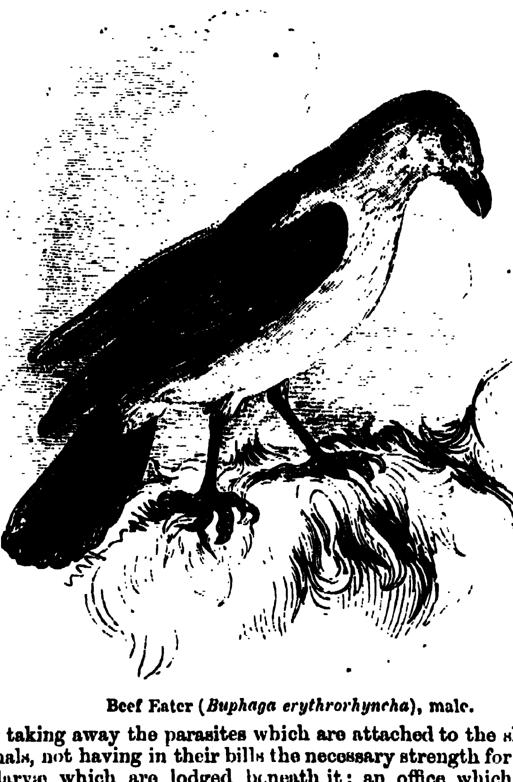
B. piniarius, the Bordered White Moth, is a beautiful moth, which when the wings are expanded measures rather more than an inch in width. Its wings on the upper side are of a dusky brown colour, and adorned with numerous pale yellow spots; and beneath clouded with the same dusky colour and having two brown stripes. The caterpillar is green, with a white longitudinal stripe down the middle of the back, and four other stripes of a yellowish colour placed two on each side of this. It feeds upon the *Pinus sylvestris* and *P. abies*, in the neighbourhood of which species of firs the moth is not uncommonly seen flying during the day-time.

(Stephens, *Illustrations of British Entomology*.)

BU'PHAGA (*Buphagus*, Brisson), a genus of Birds, whose form in some points resembles that of the *Merulidæ* (Blackbirds), while its habits approach those of the *Sturnidæ* (Starlings); but the form notwithstanding presents such strong points of difference that most ornithologists agree in viewing it as the type of a family, *Buphagidæ*, of which at present it is the only genus. The following is Temminck's generic character:—Bill strong, large, obtuse, nearly quadrangular; lower mandible stronger than the upper; both swollen towards the point. Nostrils basal, oval, half closed by a vaulted membrane. Feet moderate; shank (tarsus) longer than the middle toe; three toes before, one behind, the lateral toes equal, the external toe conjoined at the base, the internal one divided; claws hooked, compressed. Wings moderate; the first quill very short. the second nearly the length of the third, which is the longest.

The species live principally upon those parasitic insects the larvæ (maggots) of which are hatched under the skin of some of the larger ruminants and birds, a mode of life which is followed by some of the Crows (*Corvidæ*) and the Pastors. The quadrupeds on whom the *Buphaga* waits are principally those of the ox-family, the antelopes, and the camels, and generally the other ruminants both wild and tame. Fixed on the backs of these by his cramp-irons of claws the Beef-Eater, as he has been called by the English, and Pique-Bœuf by the French, digs and squeezes out with his forceps of a beak the larva that lies festering under the tough hide of the quadruped.

Le Vaillant gives the following account of the habits of *Buphaga Africana*, which is distributed through Southern Africa, and found also at Senegal:—The bill of the Pique-Bœuf is fashioned as a pair of solid pincers to facilitate the raising up out of the hides of quadrupeds the larvæ of the gadflies, which are there deposited and nourished: the species therefore anxiously seeks out the herds of oxen, of buffaloes, of antelopes—of all the quadrupeds, in short, upon which these gadflies deposit their eggs. It is while steadied by a strong gripe of the claws in the tough and hairy hide of these animals that with strong blows of the bill and powerful squeezes of the skin at the place where the bird perceives an elevation which indicates the presence of a maggot, he extracts it with effort. The animals accustomed to the treatment bear with the birds complacently, and apparently perceive the service which they render to them in freeing them from these true parasites, which live at the expense of their proper substance. The Pique-Bœufs however are not the only birds that perch upon the backs of quadrupeds and large birds, for many other omnivorous species have the same habit; but these last content themselves with only taking away the parasites which are attached to the skin of those animals, not having in their bills the necessary strength for extirpating the larvæ which are lodged beneath it; an office which the *Corvus albicollis* (Le Corbivau) executes as well as the Pique-Bœufs.



Beef Eater (*Buphaga erythrorhyncha*), male.

The Pique-Bœufs are generally seen in company, but they never fly in large flocks. Le Vaillant rarely saw more than six or eight in the same herd of buffaloes or antelopes; and M. Rüppell never observed them except in bands consisting but of few individuals about the camels of his caravan. They are very wild and difficult of approach, so that there is no chance of obtaining either the one or the other species, except by hiding behind an ox or a camel and driving it gently in the manner of a stalking horse towards those beasts on whose backs the birds are perched. When sufficiently near the fowler shows himself, and brings them down while on the wing. Besides the larvæ of the gadfly, these birds eat the ticks when they are full of blood, and all sorts of insects generally.

B. erythrorhyncha was received by Temminck some years since from the Cape of Good Hope, whither it had been brought with a number of other birds from Madagascar. Temminck says it is distinguished from its congener by a smaller and less powerful bill, by the red colour of that organ (whence it is called in French Pique-Bœuf, Bec-Corail—Beef-Eater, Coral-Bill)—by the more sombre tints of its upper plumage, and, finally, by its smaller proportions. The upper parts, head, and throat in the adult are ash-brown; glazed as it were with bluish; the lower parts are yellowish-rust or dark Isabella-colour. The total length is 7 inches, about one-third less than *B. Africana*, whose bill is yellow, and whose geographical distribution seems to lie in the southern districts and on the western coasts—parts of the country to which Temminck expresses his belief that *B. erythrorhyncha* does not penetrate. Temminck, from whose work our figure and description are taken, says that no particulars as to the structure of the nest, its position, or the period of incubation, are yet known.

BUPLEURUM (from *βοῦς*, ox, and *πλεῦρον*, side), a genus of plants belonging to the natural order *Umbelliferæ*, the sub-order *Orthospermeæ*, the tribe *Ammineæ*. It has an obsolete calyx; entire roundish petals, with a closely involute broad retuse point; the fruit subdidymous; carpels with equal winged or filiform and sharp or obsolete ridges; interstices with or without vittæ; stylopodium depressed. The species are quite smooth, herbs or shrubs. The leaves are rarely cut, in most instances being quite entire. This arises from their possessing no lamina; they are composed entirely of the petioles, and are in fact phyllodia. The flowers are yellow.

There are about fifty species of *Bupleurum*. They are natives of temperate climates in most parts of the world, and are known by the common name of Hare's-Ear. When eaten by cattle they are supposed to injure them and cause distension of the abdomen; hence the generic name. *B. rotundifolium* is the Thorow-Wax of the herbalists. It has a branched stem, with oval perfoliate leaves, and the fruit with striate interstices. It was supposed to possess especial virtues as a vulnerary, but there is no question now that wounds are better without any such applications. There are three other British species, *B. tenuissimum*, *B. aristatum*, and *B. falcatum*. The species are sometimes cultivated in gardens. The annual species only require to be sown in the open ground early in the spring. The perennial may be increased by dividing their roots; the shrubby by cuttings.

(Don. *Gard. Dict.*; Babington, *Man. of Brit. Bot.*)

BUPRE'STIDÆ, a family of Coleopterous Insects of the section *Pentamera* and sub-section *Sternoxi* (Latreille). The section *Sternoxi* is composed of two great groups or families, *Buprestidæ* and *Elateridæ*: the species of the former group are distinguished from the latter principally in having the tarsi dilated (the penultimate joints of which are bilobed) and furnished beneath with velvet-like pellets; the thorax nearly straight behind, and the mandibles entire, that is, without any notches internally near the apex; and likewise in having the terminal joints of the palpi cylindrical, or nearly so.

The form of the body in the *Buprestidæ* is somewhat ovate, the apex of the elytra being more or less pointed, and the base of the thorax of nearly equal width with that of the elytra; the head is placed almost vertically, and is deeply inserted into the thorax, so that the eyes nearly come in contact with that part.

In splendour of colouring this family of insects surpasses all others among the Beetle Tribe, the *Cetoniadæ* perhaps excepted. Green appears to be the most frequent colour, but shades of blue, red, golden or copper-like hue are not uncommon, and these colours are in most cases brilliant, or as it were burnished.

The *Buprestidæ* are found on the trunks and leaves of trees, and likewise on flowers (on the latter more particularly the smaller species), and when touched, or frequently even when approached, they apply their legs and antennæ close to the body, and allow themselves to fall to the ground, a means of escape frequently practised by insects; they crawl slowly, but in hot sunny weather are frequently on the wing, and fly rapidly.

About 500 species have been discovered belonging to this tribe, which are for the most part from the tropics. In this country about 20 species have been found at large, of these however several have most probably been imported with timber in which their larvæ feed.

The genus *Buprestis*, which is now only restricted to a few of the species of this family, is distinguished principally by the following characters:—Antennæ serrated from the third or fourth joint to the apex; labrum attenuated and slightly emarginated anteriorly; scutellum distinct; body nearly ovate.

The elytra of this genus have been found fossil at Stonesfield.

BUPRESTIS. [BUPRESTIDÆ.]

BURATITE, a mineral consisting of a Carbonate of Copper, Zinc, and Lime, with water. It occurs in bluish radiating needles. It has a specific gravity of 3·2. It is found at Chessy in France, in the Altaï Mountains, and Tuscany.

BURDOCK, the common name for the species of *Arctium*, a genus of plants belonging to the natural order *Compositæ*. This genus is distinguished by its globose involucre, the bracts terminating in hooked points, and imbricated, the flat receptacle with rigid subulate scales; the fruit compressed, oblong; the pappus short, pilose, and distinct. Two species of this genus are common in Great Britain. *A. majus*, the Greater Burdock, is characterised by its large subcorymbose heads and its cordate ovate leaves, the lowermost of which attain a very large size. *A. minus*, the Lesser Burdock, has small heads, which are racemose. The leaves are smaller than in the last species. They were both described as *Arctium Lappa* by Sir J. E. Smith.

BURGEON, or **BOURGEON**, an obsolete English and modern French name of a Leaf-Bud. [BUD.]

BURMANNIA'CEÆ, *Burmanniads*, the Burmannia Tribe, a natural order of plants belonging to Lindley's group of Epigynous Endogens. It was first constituted by Sprengel as a separate order, and is sometimes made a section of *Amaryllidaceæ*. The species of plants belonging to this order are herbaceous, with tufted radicle, acute leaves, or none at all, with terminal flowers, which are sessile upon a 2- or 3-branched rachis, or solitary. The flowers are hermaphrodite; the perianth tubular, superior, coloured, membranous, with 6 teeth, the 3 inner ones minute, the outer larger, with a wing or keel at the back; the stamens 3, inserted in the tube opposite the petals, with sessile 2-celled anthers opening transversely with a fleshy connective, and sometimes 3 sterile stamens alternate with them; the ovary inferior or 3-celled, many-seeded, with the dissepiments alternate with the wings of the perianth; the style single; the stigma 3-lobed, petaloid; the capsules covered by the withered perianth, or 3-celled, bursting irregularly; the seeds being numerous, minute, striated with an aril, fleshy albumen, and minute embryo.

The genus *Burmannia*, on which this order has been founded, is variously assigned by different botanists. Jussieu placed it in *Bromeliaceæ*, Brown in *Juncaceæ*, Von Martius in *Hydrocharaceæ*, Blume places it between *Juncaceæ* and *Iridaceæ*, Lindley between *Apostasiaceæ* and *Orchidaceæ*, and there can be little doubt of the propriety of constituting it a distinct order. The species are natives of Asia, Africa, and America. The genera referred to this order are *Burmannia*, *Gonyanthes*, *Gymnosiphon*, *Apteria*, *Dictyostega*, *Cymbocarpa*, and *Stenoptera*. There are about 30 species. They have not very conspicuous properties; the *Apteria setacea* is said by Nuttall to possess tonic and astringent properties. *Burmannia cærulea* is also said to have a flavour very similar to that of green tea.

(Lindley, *Natural System*; Burnett, *Outlines of Botany*.)

BURNET. [SANGUISORBA; POTERIUM.]

BUR-REED. [SPARGANIUM.]

BURSA'RIA, the name of a genus of Polygastric animals, with a membranous body, short, and a little bent upon itself, so as to be concave below and convex above.

Lamarck places *Bursaria* among his *Infusoria*, observing that their body is delicate and membranous, and remarkable by its concave form on one side, which sometimes puts on the appearance of a boat, sometimes of a purse. Their movements are not lively, and it is said that they are irregular, so that when they describe a spiral line from right to left and raise themselves in the water they move with tolerable swiftness; but when they return or descend they only proceed slowly, a difference of velocity attributable to their form. They are abundant in fresh and stagnant waters, and sea-water. There are many species; the most common is *Bursaria truncatella*. It is so large as to be visible to the naked eye, and is found in ditch-water.

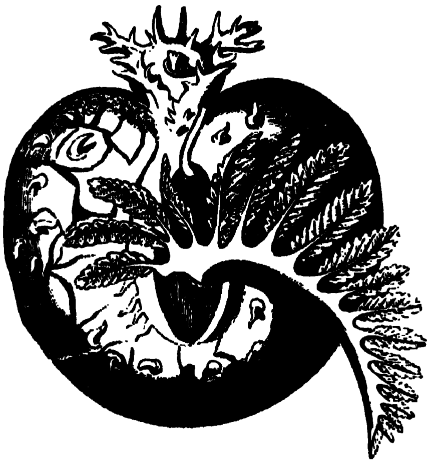
According to Ehrenberg, the *Bursariæ*, as well as the *Loxodes*, the *Trachelius*, &c., have an intestinal tube furnished with cæcal appendages which open anteriorly at the inferior surface of the body, and posteriorly at its extremity. The mouth is without cilia or hooks, and there is no ciliary circle on the front. The *Bursariæ* differ besides from the other two genera by the form of the upper lip, which is compressed, subcarinated, or swollen, and not contracted. The body of the *Bursariæ* is for the most part covered with cilia.

Some of the species are found parasitical in other animals. *B. entozoon* and *B. intestinalis*, and others, are found in the rectum of the frog.

BURSATELLA, a genus of Marine *Mollusca* without any traces of a shell, placed by De Blainville under his second family *Aplysiacea* of his third order, *Monopleurobranchiata*, of his *Paracephalophora monoica*. The following is De Blainville's definition of the genus, which, in his arrangement, comes between *Dolabella* and *Notarchus*. Rang thinks it ought to belong to the genus *Aplysia*:—

Body subglobular; below, an oval space circumscribed by thick lips, indicating the foot; above, a symmetrical oval opening with thick lips, formed by the complete junction of the natatory appendages of the mantle, and communicating with a cavity in which are found one very large free gill and the vent. The tentacula are four, divided and ramified, besides two buccal appendages.

Example, *Bursatella Leachii*, which De Blainville says is the only species of the genus. It is large, and a native of the East Indian seas.



Bursatella Leachii.

BURSERA. [BURSERACEÆ.] *Bursera paniculata* yields the *Bois de Colophane.*

BURSERA'CEÆ, a natural order of Exogenous plants, consisting of balsamic, resinous, or gummy plants with pinnated leaves and small hermaphrodite or unisexual polypetalous flowers, with a superior ovary seated in a large circular disk. The fruit is a 2-5-celled drupe, with its rind sometimes splitting into valves. It was formerly included, among other orders, in the *Terebintaceæ* of Jussieu, but it differs from *Amyridaceæ* and *Anacardiaceæ* in its compound fruit. Myrrh, frankincense, olibanum, balsam of Acouchi, gum elemi, balm of Gilead, and opobalsamum, or balsam of Mecca, are all products of different species of the order. In his 'Vegetable Kingdom,' Lindley includes this order under *Amyridaceæ.* [AMYRIDACEÆ.] It forms a *section of that order called Burseridæ.*

BUSH-BUCK. [ANTILOPEÆ.]

BUSTAMITE, a Mexican Mineral consisting of Silica, Manganese, and Lime. It occurs in spherical and reniform masses. It has a hardness of 6 to 6·5, and a specific gravity of 3·2.

BUSTARD, the English name of a Bird belonging to the genus *Otis*. The species are land-birds whose proper position in the ornithological system has caused some embarrassment to zoologists. Temminck places the genus *Otis* under his twelfth order, *Cursores* (Runners), observing that the genera *Struthio, Rhea,* and *Cassuarius* ought to stand at the head of that order. Cuvier arranges the Bustards under the *Pressirostres*, his second family of his fifth order (Échassiers,—*Grallæ*, Linn.) of birds, between the Cassowaries on one side and *Œdicnemus* (Thick-Kneed Bustard or Stone Curlew) on the other. Temminck makes *Cursorius* immediately succeed it, and observes that among the species of that genus the passage between *Otis* and *Cursorius* may be possibly found. It appears that the Bustards partake of the organisation of the Struthious, Gallinaceous, and Wading Birds (Échassiers,– *Grallatores*). *Rhea*, without alluding to the *Dodo* on the Struthious side, *Œdicnemus* on that of the Plovers, and the Turkey on the side of the Gallinaceous birds, make near approaches to the genus under consideration; while the Çariama of Brisson (*Microdactylus* of Geoffroy, *Dicholophus* of Illiger), a South American form, seems to be one of its nearest representatives on the new continent. [ÇARIAMA.] Vigors places the genus in his family *Struthionidæ* (order *Rasores*), which occupies a position between the *Cracidæ* and the *Tetraonidæ*, while it approximates to the *Gruidæ* and *Charadriadæ* in the order *Grallatores;* and, taking all the circumstances into consideration, this seems to be the best arrangement hitherto proposed.

The Bustards live generally in open countries, preferring plains or wide-spreading extensive downs dotted with low bushes and underwood—localities which give them an opportunity of descrying their enemy from afar. They are said to fly but rarely, running from danger with exceeding swiftness, and using their wings like the ostriches to accelerate their course. When they do take wing their flight is low, and they skim along the ground with a sufficiently rapid and sustained flight. Their food consists of vegetables, insects, worms, grain, and seeds. They are polygamous, one male living with many females, which, after fecundation, live solitary. Temminck says that it would seem that they moult twice a year, and that the males in the greatest number of species differ from the females in having extraordinary ornaments, and in possessing a more variegated plumage. He further observes that the young males wear the garb of the female during the first and second year, and adds his suspicion that the males in winter have the same plumage as the females. Cuvier notices their massy port and the slightly arched and vaulted upper mandible of their beak, which, with the little webs or palmations between the bases of their toes, recal the form of the Gallinaceous birds; but he adds that the nudity of the lower part of their legs, all their anatomy, and even the flavour of their flesh, place them among the *Grallatores*, and that, as they have no hind toe, their smallest species approach nearly to the Plovers.

The following is the character of the genus :—

Bill of the length of the head or shorter, straight, conical, compressed, or lightly depressed at the base; point of the upper mandible a little arched (voutée.)

Nostrils oval, open, approximated, distant from the base.

Feet long, naked above the knee; three front toes short, united at their base, bordered by membranes.

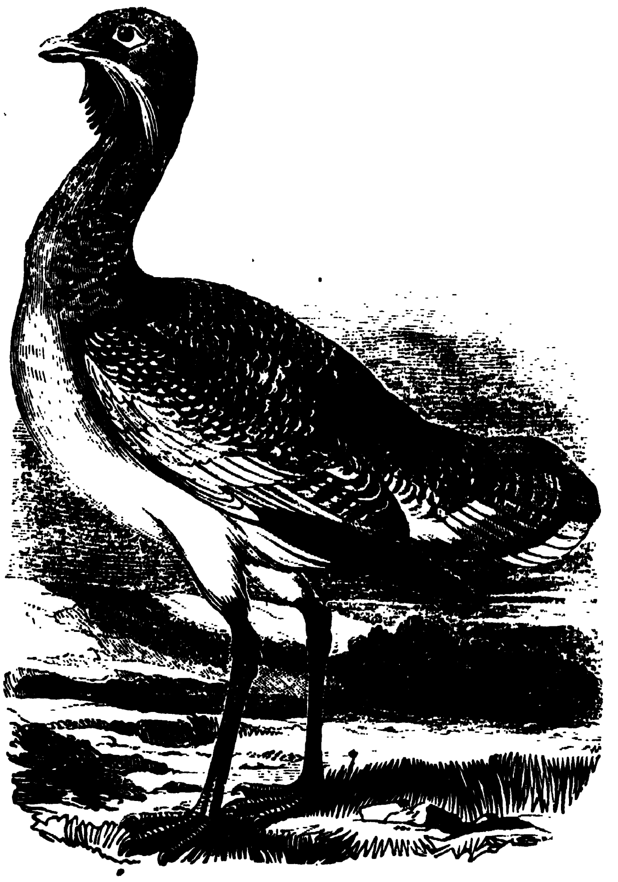
Wings moderate, the third quill longest in each wing.

They are found in Europe, Asia, and Africa; but not in America.

O. tarda, the Great Bustard, is the *Otis* and *Avis tarda* of Bélon and others; Ostarde, Houtarde, Outarde, Bistarde of the French; Starda and Starda Commune of the Italians; Der Grosse Trappe, Trapp, Trappgans, and Ackentrapp of the Germans; Abutarda (*Avis tarda*) of the Spaniards; and Gustard of the old Scotch.

From passages in the 'History of Animals' (ii. 17, vi. 6), there can be scarcely a doubt that our Great Bustard is Aristotle's 'Ωτίς. Indeed the doubts originated in a misunderstood passage in the thirty-third chapter of his ninth book; and it is clear from several authorities that the bird and the quality of its flesh were well known to the Greeks. Pliny evidently alludes to these birds as those "quas Hispania aves tardas appellat, Græcia otidas" ('Nat. Hist.' x. 22); though he blunders about the flesh, telling an absurd story of its effects, which arises from his confounding the ὠτίς with Aristotle's ὠτός, an owl.

The following is the description of this bird given by Mr. Selby :- The male has the bill strong, grayish-white; the under mandible palest. Head, nape of the neck, and ear-coverts, bluish-gray. A streak of black passes along the crown of the head, reaching to the occiput. Chin-feathers and moustaches composed of long wiry feathers, with the barbs disunited and short. Fore part of the neck clothed with a naked bluish-black skin, extending upwards toward the ear-coverts, and covering the gular pouch. Sides of the neck white, tinged with gray; lower part of the neck fine reddish-orange. At the setting on of the neck, or between the shoulders, is a space destitute of feathers, but covered with a soft gray down. Scapulars buff-orange, barred and spotted with black. Back, rump, and tail-coverts, reddish-orange, barred and variegated with black. Greater coverts and some of the secondaries bluish-gray, passing towards the tips into grayish-white. Quills brownish-black, with their shafts white. Tail-feathers white at their bases, passing towards the middle into brownish-orange, with one or two black bars; the tips often white, and, when the feathers



Great Bustard (*Otis tarda*), male.

are spread laterally, forming a segment of a circle. Upper part of the breast reddish-orange; lower part, belly, and vent, white. Legs black, covered with round scales. Irides reddish-brown. The possession of a gular pouch by these birds, which was first recorded by Dr. Douglass, seems to be a mistake, as Mr. Yarrell in dissecting a male bustard has failed to detect this organ. The average length of a male is 3 feet 3 inches.

The female has the head and forepart of the neck of a deeper gray, and without the moustaches. Back of the lower part of the neck reddish-orange. The other parts of the plumage similar to that of the other sex. Size seldom more than one-third of that of the male.

Great Bustard (*Otis tarda*), female.

The young at a month old are covered with a buff-coloured down, barred upon the back, wings, and sides with black.

With regard to its distribution, Selby says, "It is found in some provinces of France and in parts of Germany and Italy. It is common in Russia and on the extensive plains of Tartary." Temminck states that it inhabits some departments of France, of Italy, and Germany: that it is less abundant towards the north than in the south; and that it is very rarely and accidentally found in Holland. Graves relates that the species is dispersed over the southern parts of Europe, and the more temperate parts of Africa, and is very abundant in some parts of Spain and Portugal. In our own islands the increase of population and civilisation, followed by greater demands on the land, and consequently by an extension of cultivated surface, have so reduced the Bustards, that unless care be taken to preserve the few which remain, they will soon be numbered among the other extinct species of our Fauna. The following are notices of the old British localities of these noble birds. "They are called," says Willughby, "by the Scots *Gustardæ*, as Hector Boëthius witnesseth in these words:—In March, a province of Scotland, are birds bred, called in the vulgar dialect *Gustardes*, the colour of whose feathers and their flesh is not unlike the partridges, but the bulk of their body exceeds the swans." The editor of the last edition of Pennant states that in Sir Robert Sibbald's time, they were found in the Mers, but that he believes that they are now extinct in Scotland. Willughby also says (1678), "On Newmarket and Royston Heaths, in Cambridgeshire and Suffolk, and elsewhere, in wastes and plains they are found with us." Ray (1713) thus writes:—"In campis spatiosis circa Novum Mercatum (Newmarket) et Royston, oppida in agro Cantabrigiensi, inque planitie, ut audio, Salisburiensi, et alibi in vastis et apertis locis, invenitur." In Brookes's 'Ornithology' (1761) the following passage occurs:—"This bird (the bustard) is bred in several parts of Europe, and particularly in England, especially on Salisbury Plain, Newmarket and Royston Heaths, in Cambridgeshire and Suffolk; for it delights in large open places. The flesh is in high esteem, and perhaps the more so because it is not very easy to come at." Pennant says, "These birds inhabit most of the open countries of the south and east parts of this island from Dorsetshire as far as the Wolds in Yorkshire."

The editor of the last edition (1812) observes that "the breed is now nearly extirpated, except on the Downs of Wiltshire, where it is also very scarce." The figure of the male bird given by Graves is said to have been drawn from one taken alive on Salisbury Plain in 1797. Montagu in his 'Dictionary' (1802) says that in this locality it had become very rare from the great price given for the eggs and young to hatch and rear in confinement. In his 'Supplement' (1813) he states that not one had been seen there for two or three years previous. Graves says that, in the spring of 1814, he saw five birds on the extensive plains between Thetford and Brandon, in Norfolk, from which neighbourhood in 1819 he received a single egg, which had been found in a large warren. In the autumn of 1819, he adds, a large male bird which had been surprised by a dog on Newmarket Heath, was sold in Leadenhall Market for five guineas; and in the same year, he continues, a female was captured under similar circumstances on one of the moors in Yorkshire. When the mania for real British specimens of birds was prevalent, the bustards suffered not a little. We know a collector who, about the year 1816, had nine dead bustards before him together: they came from Norfolk. In 1830 a young male was shot on Shelford Common, in Cambridgeshire, and in 1832 a specimen was killed at Caxton in the same county. In 1843 one was shot in Cornwall on an open plain between Helston and the Lizard Point. It is very certain, from these notices, that this bird is becoming every day more rare in England, and will probably soon be wholly absent from its Fauna.

With regard to its food Willughby says that the Bustard feeds upon corn, seeds of herbs, colewort, dandelion leaves, &c. In the stomach of one which he dissected he found a great quantity of hemlock-seed, with three or four grains of barley, and that in harvest time. Brookes states that they feed upon frogs, mice, small birds, and different kinds of insects. Pennant makes their food to consist of corn and other vegetables, and those large earth-worms that appear on the Downs before sun-rising in the summer. Montagu states it to be green corn, the tops of turnips, and various other vegetables, as well as worms; but adds, that they have been known to eat frogs, mice, and young birds of the smaller kind, which they can swallow whole. Turnip-tops are certainly a favourite article of diet with these birds; and we believe that the nine bustards above mentioned owed their fate to their fondness for this vegetable—being laid in wait for at their feeding-time. Temminck says that their nourishment consists very much of insects and worms, and also of grain and seeds.

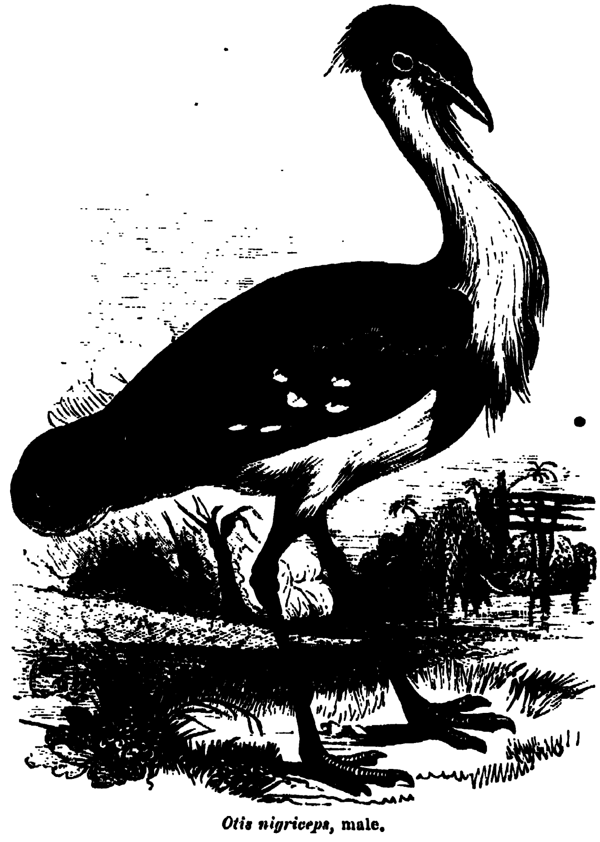
The eggs of the Bustard, two in number generally, sometimes three, are laid upon the bare ground, which is often a little hollowed out by the female (occasionally, says Selby, among clover, but more frequently in corn-fields), early in the spring. They rather exceed those of a turkey in size, and their colour is a yellowish-brown, inclining to oil-green, with slight darker variations. Time of incubation four weeks. The young as soon as hatched follow the parent, but are incapable of flight for a long time.

The extreme rapidity of their running, and the unwillingness to rise on the wing exhibited by these birds, have been the theme of most ornithologists. We have also many accounts of their being coursed with dogs. The following is from Brookes:—"There are also bustards in France which frequent large open plains, particularly near Chalons, where in the winter time there are great numbers of them seen together. There is always one placed as a sentinel, at some distance from the flock, which gives notice to the rest of any danger. They raise themselves from the ground with great difficulty; for they run sometimes a good way, beating their wings before they fly. They take them with a hook baited with an apple or flesh. Sometimes fowlers shoot them as they lie concealed behind some eminence, or on a load of straw; others take them with greyhounds, which often catch them before they are able to rise." Selby, who has evidently had good opportunities of observation, thus writes in his 'Illustrations:'—"Although, in a state of confinement, the bustard becomes tolerably tame to those who are in the habit of attending it, yet it displays at all times considerable ferocity towards strangers; and all attempts to continue the breed in that state have been without success. With respect to its habits in the wild state, it is so shy as seldom to be approached within gun-shot; invariably selecting the centre of the largest inclosure, where it walks slowly about, or stands with the head reposing backwards upon the bare part of its neck, and frequently with one leg drawn up. Upon being disturbed, so far from running in preference to flight (as has been often described), it rises upon the wing with great facility, and flies with much strength and swiftness, usually to another haunt, which will sometimes be at the distance of six or seven miles. It has also been said that in former days when the species was of common occurrence, it was a practice to run the young birds (before they were able to fly) with greyhounds. So far from this possibility existing with the present remnant of the breed, the young birds upon being alarmed constantly squat close to the ground, in the same manner as the young of the lapwing, golden plover, &c., and in that position are frequently taken by hand; indeed this is even the habit of the female during incubation." Selby's remarks on its powers of flying are corroborated by the 'Booke of Falconrie or Hawking' (1611), where, under the head of 'Other flights to the fielde called great flights,' at p. 83, we find it thus written:—"There is yet another kind of flight to the fielde, called the great flight, as to the cranes, wild geese, bustard, bird of paradise, bittors, shovelars, hearons, and many other such like, and these you may flee from the fist, which is properly tearmed the source. Neverthelesse, in this kind of hawking, which is called the Great Flight, the falcons or other hawkes cannot well accomplish their flight at the cranes, bustard, or such like, unlesse they have the helpe of some spaniell, or such dogge, wel inured and taught for that purpose with your hawke. Forasmuch as great flights require pleasant ayde and assistance, yea and that with great diligence." As an article of food the flesh of the bustard is held in great estimation. It is dark in colour, short in fibre, but sweet and well-flavoured.

O. tetrax, the Little Bustard, is only an accidental winter visitor in Great Britain. Specimens have been killed in various parts of our coast. It is frequent in the southern and south-western parts of Russia. It is common in France, and also found in Spain, Provence, Sardinia, Italy, and Sicily. It is also an inhabitant of North Africa, Turkey, and Greece.

O. nigriceps is a native of Asia. The specimen from which the figure in Mr. Gould's magnificent work ('Century of Birds from the Himalaya Mountains') was taken was brought from the highlands of the Himalaya, but it is by no means confined to that locality. Colonel Sykes observed it in the wide and open country of the Mahrattas, where it lives in large flocks, and where it is considered one of the greatest delicacies as an article of food. It is indeed so abundant in the Deccan, that Colonel Sykes records, in the 'Proceedings of the Zoological Society,' that one gentleman shot nearly a thousand.

The male has the body above pale bay, lightly undulated with rufous-brown; neck, a few spots on the wings, and belly, white; the head, which is crested, the outer wing-coverts, the quills, and the large mark on the breast, black; irides deep-brown; bill and feet yellowish. Length, inclusive of tail, 56½ inches; tail, 13½ inches.



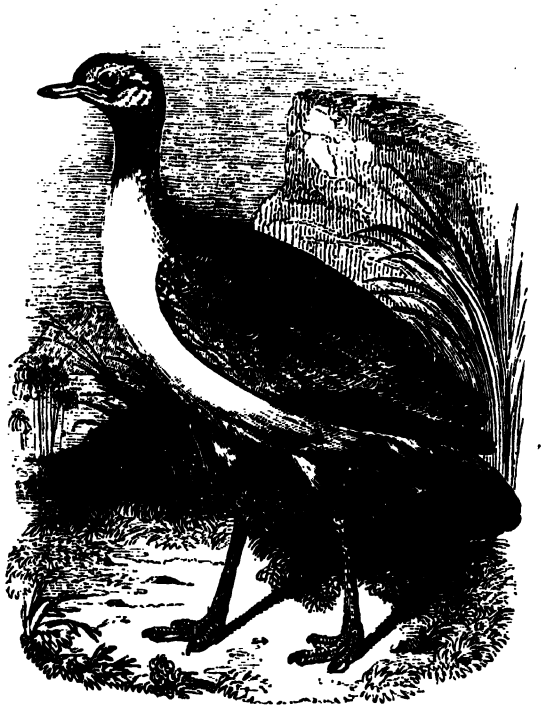
Otis nigriceps, male.

The female resembles the male in plumage, but is only 41½ inche including the tail, which is 10½ inches.

The eggs, of which Colonel Sykes found only one in a hole in th earth on the open plain and that considerably advanced in the proces of incubation, were in shape a perfect oval, and in colour a brown-olive, with obscure blotches of darker brown-olive. Length 3$\frac{4}{10}$ inches, diameter 2$\frac{7}{10}$ inches.

O. cærulescens is an inhabitant of Africa. The summit of the head is marked with black and reddish zig-zags, straight and nearly approximated. Above the eyes extends a large whitish band, punctured a it were with brown; plumes near the ear-opening of a clear rudd colour. Under the neck a demi-circular band of pure white; an below another twice as large, of deep black. Front of the neck, breast, and all the other lower parts of a lead-colour. All the uppe parts of the body of a reddish or yellowish brown, marked with blacl zig-zags and dots very nearly together. Lower coverts of the wings an tail-feathers unspotted, ruddy. End of the tail black, tinged with brown. Quills black. Feet yellowish-green. Bill brown, yellow at the base. Length 20 inches; height, when erect, 17 inches 6 lines.

Le Vaillant discovered this species in the interior of South Africa, inhabiting the Kaffir country and some parts of the colony of the Cape of Good Hope. Temminck, from whom the description and figure are taken, says that he is ignorant whether the female differs in plumage from the male, of which latter sex were the two individuals he had seen. There are specimens in the museums of Paris and of the Netherlands.



Otis cærulescens, male.

O. Denhami, the African Bustard met with by Major Denham near the larger towns, did not occur in any great abundance. It frequented moist places where the herbage was pure and fresh, and where it was taken in snares by the natives for food. It was almost invariably seen singly, Major Denham never having observed a pair together more than once. It was always found in company with gazelles: whenever a bustard was observed it was certain that the gazelles were not far distant. Major Denham praises its large and brilliant eye. The Arabs are accustomed to compare the eyes of their most beautiful women to those of the Oubara, which seems to be a general name for the bustards in Africa. Gmelin has given the title as a specific distinction to an African bustard smaller than Major Denham's, which is 3 feet 9 inches in length. But this is small in comparison with the Kori Bustard (*Otis Kori*) discovered by Mr. Burchell in South Africa, for that stood upwards of 5 feet high, and may be considered the most gigantic development of the form hitherto observed.

Head of Kori Bustard (*Otis Kori*).

Burchell, in his Travels in the interior of Southern Africa, gives the following account of his becoming possessed of this noble Bustard on the banks of the Orange River:—"We shot a large bird of the bustard kind, which was called Wilde Paauw (Wild Peacock). This name is here very wrongly applied, as the bird to which it properly belongs differs from this in every respect. There are indeed three, or perhaps four, birds to which in different districts this appellation is given. The present species, which is called Kori in the Sichuana language, measured in extent of wing not less than 7 feet, and in bulk and weight was almost greater than some of the people could manage. The under part of the body was white, but the upper part was covered with fine lines of black on a light chestnut-coloured ground. The tail and quill-feathers partook of the general colouring of the back; the shoulders were marked with large blotches of black and white, and the top of the head was black; the feathers of the occiput were elongated into a crest; those of the neck were also elongated, loose, narrow, and pointed, and were of a whitish colour marked with numerous transverse lines of black. The irides were of a beautiful, pellucid, changeable, silvery, ferruginous colour. A representation of the head of the Kori Bustard is given at the end of the chapter. Its body was so thickly protected by feathers that our largest sized shot made no impression, and taught by experience the hunters never fire at it but with a bullet. It is reckoned the best of the winged game in the country, not only on account of its size but because it is always found to abound in fat. The meat of it is not unlike that of a turkey, but is certainly superior as possessing the flavour of game."

BUTCHER-BIRD. [Laniadæ.]

BUTCHER'S-BROOM. [Ruscus.]

BU'TEA, a genus of plants belonging to the natural order *Leguminosæ*, named after John, Earl of Bute, a great patron of botanists. It has a campanulate calyx, 5-toothed, the two superior teeth approximate and almost connected; the corolla with a lanceolate spreading vexillum; keel incurved, equal in length to wings and vexillum; the stamens diadelphous; the legume stipitate, compressed, flat, membranous, indehiscent, 1-seeded at the apex; the seed large, compressed. The species are natives of the East Indies. They are unarmed trees, with pinnately trifoliate leaves, with racemes of deep scarlet flowers.

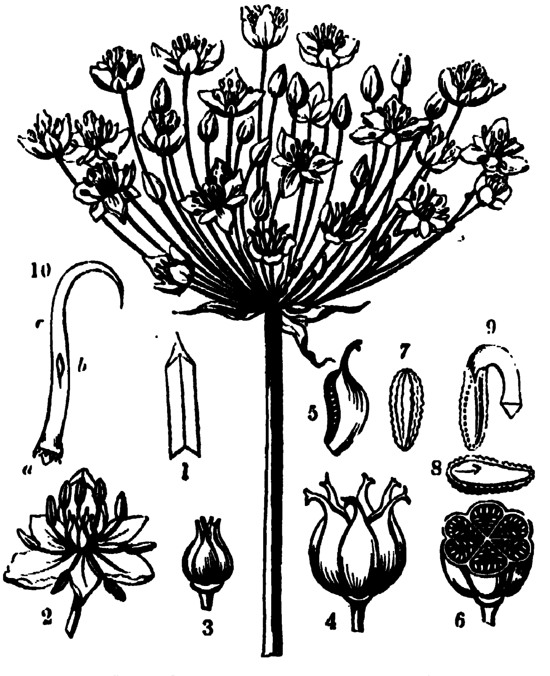
B. frondosa has pubescent branches; roundish obtuse or emarginate leaflets, velvety beneath; the corolla four times the length of the calyx; the calycine teeth rather acute. It is a native of mountainous districts in Hindustan. A red juice flows from this tree, which when evaporated is found to consist principally of tannin, and is brought into the market under the name of East Indian Kino. The juice of the common flowers, which in this species are two inches long, gives to water a bright yellow colour similar to gamboge. This property is also possessed by the dried petals. "The lac insects are frequently found upon the smaller branches of the tree, but whether the natural juices of its bark contribute to improve their red colouring matter has not been determined." (G. Don.)

B. superba has glabrous branches; roundish ovate obtuse leaflets, velvety beneath; the corolla four times the length of the calyx; calyx-teeth acute. It grows on the mountains of Coromandel. It resembles the last species, but is larger in all its parts. It yields the same kind of juice. There are two other species described.

(G. Don, *Gardener's Dictionary*; Lindley, *Vegetable Kingdom*.)

BUTEO, a genus of Birds belonging to the order *Raptores* and the family *Falconidæ*. It includes, according to Yarrell, two British species, *B. vulgaris*, the Common Buzzard, and *B. lagopus*, the Rough-Legged Buzzard. [Falconidæ.] Various other species of the *Falconidæ* have been included under this generic name. (Yarrell, *British Birds*.)

BUTOMA'CEÆ, *Butomads*, the Butomus Tribe, a natural order of Endogens, the type of which is the *Butomus umbellatus*, a common water-plant of this country. It is vulgarly called the Flowering Rush, and is accounted the handsomest herbaceous plant of the British Flora. *Butomaceæ* are briefly characterised by being Tripetaloideous Endogens (that is, with three sepals distinct in size and colour from the three petals), with several carpels, the whole lining of which is covered with seeds. This simple circumstance cuts them off from *Alismaceæ*, with which they were once associated, and also distinguishes them from all other monocotyledonous orders. The order is a very small one, not containing more than three known genera, and about half a dozen species, natives of equinoctial America, exclusive of the *Butomus umbellatus* of England, and another species of the same genus occurring in Nepal.



Flowering Rush (*Butomus umbellatus*).

1, A section of a portion of a leaf; 2, an entire flower; 3, the carpels; 4, the ripe fruit; 5, a seperate carpel; 6, a transverse section, showing how the whole lining of the ripe carpels is covered with seeds; 7, a seed much magnified; 8, a longitudinal section of the same; 9, a seed germinating; 10, the same in a more advanced state; *c*, the cotyledon; *b*, the plumule sprouting; *a*, the radicle just bursting through its integuments. (N.B. This offers an illustration of the endorhizal mode of germination.)

Butomus umbellatus is a rush-like plant with three-cornered sword-shaped leaves, and umbels of handsome rose-coloured flowers, containing nine stamens, a peculiarity by which it is immediately recognised among other wild flowers. The roots of it are regarded in Russia as a specific in hydrophobia; but experiments made with them in this country have not confirmed the accounts of their influence in this utterly incurable disease recorded by the Russian physicians.

BUTT, a name for the Flounder. [Platessa.]

BUTTER-BUR. [Petasites.]

BUTTER-FISH. [Murænoides.]

BUTTERFLY. [Lepidoptera.]

BUTTERFLY-FISH. [Blennius.]

BUTTERFLY-ORCHIS. [Platanthera.]

BUTTERFLY-PLANT. [Oncidium.]

BUTTERFLY-WEED, a name given in the United States to the *Asclepias tuberosa*. [Asclepias.]

BUTTERS, VEGETABLE, the name given to the concrete oil of certain vegetables, from its resemblance to the butter obtained from the milk of animals, and from being employed for similar purposes. The term is also occasionally, but improperly, applied to some vegetable products which are entirely of a waxy nature, such as the wax of the *Myrica cerifera*. The name is likewise bestowed in Siberia on certain algæ, species of the genus *Nostoc*, such as *N. pruniforme*. The most important Vegetable Butters are produced by the *Bassia butyracea* and other species of that genus (*Bassia*) and certain palms, such as the *Cocos butyracea* and the *Elais Guineensis*; the former of which is of great utility to the inhabitants of Brazil, where it grows naturally, and to the negroes of St. Domingo, where it is cultivated; while the latter is very serviceable to the natives of Guinea.

(*Library of Entertaining Knowledge—Vegetable Substances, Materials of Manufacture*, p. 221.)

BUTTER-TREE. [Bassia.]

BUTTERWORT. [Pinguicula.]

BUXBAUMIA, a genus of plants belonging to the natural order of Mosses. It was named in honour of J. C. Buxbaum, a German botanist, and author of a catalogue of plants of the environs of Halle, and who first detected this moss in Russia. *Buxbaumia* has an oblique gibbous capsule; a double peristome, the outer consisting of numerous filiform erect jointless teeth, the inner a plaited membranous cone; a minute mitriform calyptra. There is but one species of this singular genus, the *B. aphylla*. This plant is destitute of apparent leaves, and looks more like a fungus than a moss. The ascending axis of the plant is in fact reduced to a little conical bulb, which is clothed with minute scales, and these Mr. Robert Brown pointed out as its leaves. From the bulb arises a red tuberculated seta bearing the reproductive organs, which is about an inch high. It is a very rare plant. It was first discovered in Great Britain at Sproughton near Norwich. It has also been found in three or four localities in Scotland. (Smith's *English Flora*, vol. v.)

BUXUS, the genus of plants whose species afford the valuable hard wood called Box. It is remarkable botanically as being the most northern arborescent plant of the natural order *Euphorbiaceæ*, all the other trees of which are confined to mild or tropical climates. Its essential character is to have both the male and female flowers upon the same individual; a 3- or 4-parted calyx; in the males a 2-lobed scale and 4 stamens placed round the rudiment of an ovary; in the females 3 small scales, 3 styles, 3 blunt stigmas, and a 3-horned 3-celled 6-seeded capsular fruit.

The only two certain species are *B. sempervirens* and *B. Balearica*. The former, or common Box, forms a large evergreen bush or small tree, common all over the south of Europe, from Spain to Constantinople, and reaching even so far as the north of Persia. In this country it is only found on warm chalky hills. Many varieties are known in gardens, the most remarkable of which is the Dwarf-Box, so much used for the edgings of walks. Between this and the arborescent form the difference is so great, that one wonders how they can be both the same species, and Miller and others have even considered them distinct. But De Candolle states that the wild plant in France is very variable in size, rising in some places to the height of 15 or 20 feet, and in rocky localities not exceeding 3 feet. It is from the arborescent *Buxus sempervirens* that box-wood is obtained. For the turner, for mathematical instruments, and especially for the uses of the wood-engraver, it is invaluable. The French employ it for coat-buttons, &c. "The value of the box-wood sent from Spain to Paris is reported to amount to about 10,000 francs a year. In 1815, the box-trees cut down on Box-Hill, near Dorking in Surrey, produced upwards of 10,000*l*." (Macculloch, 'Dictionary of Commerce.') Great quantities are imported from Turkey, and of fine quality. The leaves have been employed, medicinally, as a tonic, a substitute for Peruvian bark.

Buxus Balearica, the Majorca Box, is a handsomer plant than the other, with broader leaves, and a more rapid growth; but it is much more impatient of cold. Plants of it however live in the neighbourhood of London without protection. It is found wild in the neighbourhood of Lluch in Majorca, on the hills, at the height of 1500 feet; and it also occurs abundantly on Mount Galatzo, where it is mingled with the palmetto, but not in great masses. We find nothing in books concerning the quality of its wood; but there is reason to suppose that a part at least of the Spanish and Turkey box-wood is furnished by this species.

BUZZARD. [FALCONIDÆ.]

BYRRHUS, a genus of Coleopterous Insects, instituted by Linnæus, belonging to the family of *Byrrhidæ* as defined by Leach. The Beetles composing it are more or less globose, very convex, and sericeous; the club of their antennæ is 5-jointed, and is gradually thickened to the extremity. The elytra cover the body, and the animal can so contract its legs as to pack them in cavities adapted for their reception on the under side of the body. This it does when alarmed, simulating death. The larva of the common species, the *Byrrhus pilula*, popularly known as the Pill-Beetle, is of an elongate form, narrow, with a large head, the dorsal plate of the first segment large, and the two terminal segments larger than the others. Seven British species of *Byrrhus* are enumerated by Mr. Stephens in his 'Systematic Catalogue of British Insects.' (Westwood, *Introduction to Entomology.*)

BYRSONIMA, a genus of plants belonging to the natural order *Malpighiaceæ.* The bark of the species is astringent, and is used extensively for tanning in the Brazils. The wood of some of the species, especially *B. verbascifolia*, is of a bright red. The bark of *B. crassifolia* is used in fevers. *B. crassifolia* is one of the thousand remedies for rattlesnake bites. It is called Chapera Mantoca. The Alcornoco Bark is the produce of *B. laurifolia, B. rhopalæfolia*, and *B. coccolobæfolia.* The acid and astringent berries of *B. spicata* are said to be good in dysentery. (Lindley, *Vegetable Kingdom.*)

BYSSA'CEÆ, a tribe of Cryptogamic Plants, raised by some botanists to the importance of a distinct order, whilst others refer it either to the Lichens or the *Fungi*, or distribute its genera amongst the various orders of *Cryptogamia.* Fries places this group of plants in the natural order of Lichens, with the following definition:—"Aerial, perennial, constantly growing, with a filamentous texture, consisting of solid fibres (either few, or several glued together, with a common bark), unchanged and permanent. Fructification homogeneous, growing externally and naked." Many of the species of plants referred to this order are of a very doubtful nature, and particular states of decaying vegetable and animal matter have undoubtedly been described as plants, and placed amongst them. These forms of matter, whatever they may be, are not less interesting to the naturalist than if they came under his definition of a plant.

The genus *Rhizomorpha* [RHIZOMORPHA] is referred by most botanists to *Byssaceæ.* Some authors have doubted their specific vegetable character. The various forms are found on decaying wood, and in mines, pits, and dark places. In the coal-mines of Dresden they form objects of great interest on account of their phosphorescence. Mr. Erdmann, quoted by Burnett in his 'Outlines of Botany,' gives the following account of this phenomenon in one of the Dresden mines:—"I saw," he says, "the luminous plants here in wonderful beauty; the impression produced by the spectacle I shall never forget. It appeared, on descending into the mine, as if we were entering an enchanted castle. The abundance of these plants was so great that the roof and walls and the pillars were entirely covered with them, and the beautiful light they cast around almost dazzled the eye. The light they give out is like faint moonshine, so that two persons near each other could readily distinguish their bodies. The lights appear to be most considerable when the temperature of the mines is comparatively high." One of the species, *Rhizomorpha cinchonarum*, is found on the cinchona barks of commerce, and is a sure indication of their worthless state. Another species of *Byssaceæ, Himantia cinchonarum* of Fée, is an evidence of the subputrescent state of the barks on which it is found. *Racodium* is a genus referred by Fries to this group of plants. The *R. cellare* is a common plant in wine-cellars, where it forms a kind of tapestry on the walls and roofs, investing the casks and bottles with a tunic resembling in colour and appearance the skin of a mouse. *Hypochnus* is a genus found on the decaying bark of trees. When found on barks used for medicinal purposes, they should be rejected as unfit for use, as this plant indicates incipient decay.

The genera *Monilia* and *Aspergillus* are sometimes referred to *Byssaceæ.* The species of these genera, with many others, form what is known by the name of Mould on various substances. [MOULDINESS.] *Monilia penicillata* is commonly found on plants in herbaria. The various forms of *Aspergillus* are found on all kinds of decaying substances. *A. glaucus* is the blue-mould which forms on cheese, lard, bread, &c. It gives a value to cheese, and its colour is often imitated by fraudulent dealers by sticking brass pins into the cheese, the verdigris formed from the pins giving it the colour of mould.

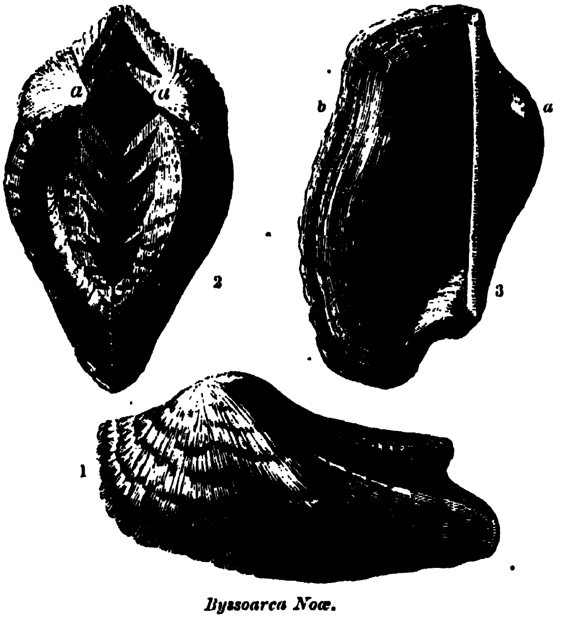
Most of the species of the old genus *Byssus* are distributed amongst other genera. *B. Iolithus*, the Violet-Scented Byssus, is found of a deep red colour on boarded buildings, old pales, and trunks of trees, on rocks in mountainous countries, and on walls. It is now called *Lepraria Iolithus.* It is not less remarkable for its violet scent than its red colour. [SNOW, RED.] There is another plant, *Chroolepus Iolithus*, which was included under the *Byssus Iolithus* of older writers. *Byssus Cryptarum* forms the genus *Tophora* of recent writers. Several species of *Tophora* have been named. They do not however produce spores, and by some they are supposed to arise from the germination of the spores of ferns and mosses arrested in the rudimental state. The *Lepraria* are sometimes referred to *Byssaceæ*, but they seem to be the commencing point of the organisation of true Lichens. They have a thallus resembling a scurf which is formed of sporules. They are very common on decaying timber of all kinds.

The cells of the leaves of many plants during decay assume a variety of forms which have been described as cryptogamic plants, under the genera *Phyllerium, Erineum, Grumaria, Taphria*, &c. [FUNGI.] Many of these so-called plants are meteoric productions. "On one occasion they are said to have suddenly overrun all the leaves of pines on the side next the wind in the neighbourhood of Dresden; on another, on the 29th of August, 1830, to have in an instant spread over the sails and masts of a ship at Stockholm; and Fries is disposed to consider the cobweb-like matter that overruns the grass in the mornings of spring and autumn of this nature, and not of animal origin." (Lindley.)

(Lindley, *Vegetable Kingdom;* Burnett, *Outlines;* Smith, *English Flora.*)

BYSSOARCA, a sub-genus of *Mollusca*, separated by Swainson from the genus *Arca* of Linnæus, and considered by the former as the sedentary type of that genus. The following is the sub-generic character given by Swainson in his second series of 'Zoological Illustrations:'—Animal fixed by byssiform filaments to other bodies; shell transverse; umbones remote; valves gaping in the middle of the ventral margin.

"The animals of these shells," says the author last quoted, "affix themselves to other bodies by a particular muscle, which is protruded through the gaping part of the valves; they also adhere when young by the byssiform epidermis which covers the exterior." Mr. G. B. Sowerby has described several new species collected by Mr. Cuning on the western coast of South America and among the islands of the South Pacific Ocean, in the 'Proceedings of the Zoological Society of London' for 1853. *Byssoarca* has been found moored to stones and shells at depths varying from the surface to 75 fathoms.



Byssoarca Noæ.

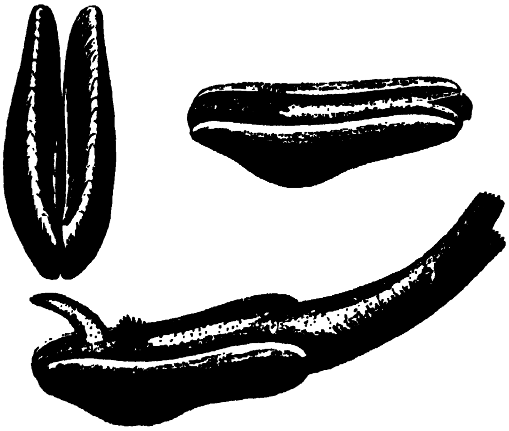
1, Valves closed; 2, valves closed, view of the hinge area; 3, a single valve, showing the hinge teeth and the interior of the valve; *a*, umbones; *b*, part of the ventral margin where the valves gape, to give room for the extrusion of the tendinous foot.

BYSSOMYA, a genus of Conchiferous Mollusks, separated by Cuvier and placed by him under his Acephalous *Testacea*, between *Pandora* and *Hiatella.* De Blainville, who approves of Cuvier's separation, observing that, though the shell differs little from *Saxicava*, the animal is very distinct, arranges it in his family of *Pyloridea*, between *Saxicava* and *Rhomboides.*

Generic Character.—Animal more or less elongated, subcylindrical, elongated behind by a long tube, which is bifurcated at its extremity only. A hole at the lower and anterior part of the mantle for the passage of a small conical canaliculated foot, and of a byssus situated at its posterior base. Two strong adductor muscles.

Shell often irregular, covered with a strong epidermis, oblong, strongly striated longitudinally, equivalve, very inequilateral, obtuse and wider before, and attenuated or rostrated as it were behind. Umbones but little developed, though distinct and a little curved forward. Hinge toothless, or only having a rudiment of teeth under the corselet. External ligament rather long. Two strong, distant, and rounded muscular impressions.

Example, *Byssomya pholadis*, *Saxicava pholadis* of Lamarck. The species inhabits the northern seas, living in the fissures of rocks in company with *Mytili* (Mussels), and attached by its byssus; but sometimes it buries itself in the sand or lodges in small stones, the roots of *Fuci*, and even in the polymorphous *Millepora*: in the latter cases, according to O. Fabricius, it is without byssus.

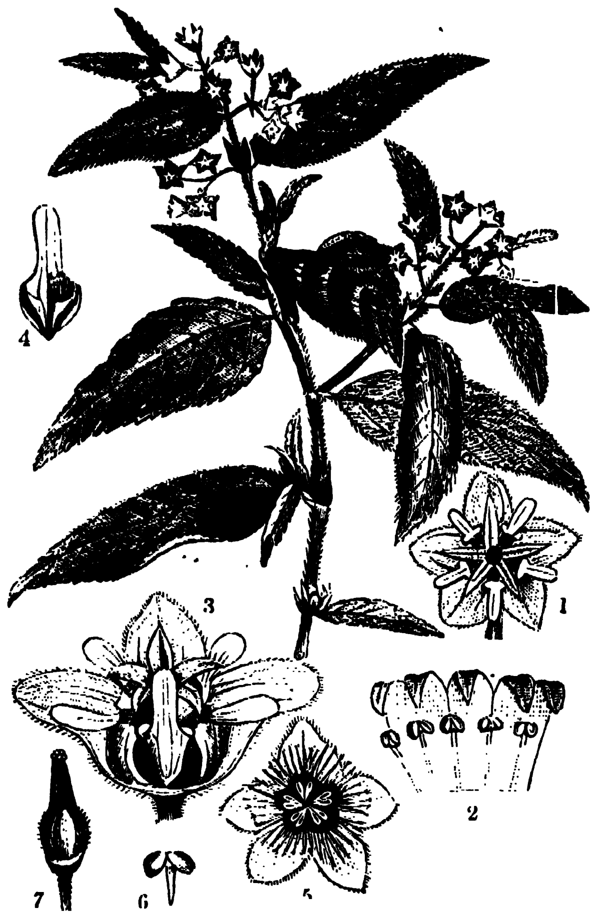


Byssomya pholadis.

Forbes and Hanley, in the 'History of British Mollusca,' refer *B. pholadis* of Bowdich and the *S. pholadis* of Lamarck as synonymous to *Saxicava rugosa*. [SAXICAVA.]

BYSSUS, the name of a long, delicate, lustrous, and silky fasciculus of filaments, by which some of the conchiferous mollusks (the *Mytilacea*, Mussels, and *Malleacea*, Hammer Oysters, for example) are moored to submarine rocks, &c. This is not, as some authors have stated, a secretion spun by the animal, but, according to De Blainville, an assemblage of muscular fibres dried up in one part of their extent, still contractile and in a living state at their origin, a condition which they enjoyed throughout their whole length at the period of their attachment. The tendinous foot of *Byssoarca* and *Tridacna* seems to be a step towards the organisation of a true byssus. In the great *Pinna* of the Mediterranean this substance is well and largely developed, and its situation is in a fleshy sac or sheath at the base of the foot, which is attached towards the middle of the abdominal mass of the animal. In Italy the byssus is manufactured into various articles; and there are few museums without a glove or a stocking woven out of this substance. In the Great Exhibition of 1851 a large number of articles were exhibited manufactured from this substance, as well as specimens of the silk for making up.

BYTTNERIA'CEÆ, *Byttneriads*, the Byttneria Tribe, a group of plants by some botanists considered a distinct natural order, by others reduced to a section of *Sterculiaceæ*. They belong to Lindley's Malval alliance of Exogens, and are readily known by their petals being bagged at the base, their stamens partly sterile and petaloid, and their fruit covered with hooked spiny hairs. From *Sterculiaceæ* proper they differ by the presence of petals, and their stamens not being united into a column; from *Malvaceæ* by their 2-celled anthers and bagged petals; and from *Lasiopetaleæ* by their calyx not being coloured like a corolla, and their petals not rudimentary. The species are chiefly inhabitants of tropical countries. They partake of the mucilaginous inert properties of *Malvaceæ*. Their bark often yields a tough fibre fit for manufacture into cordage; and one species, *Theobroma Cacao* [THEOBROMA], produces the seeds from which the buttery and somewhat bitter substance called cocoa is obtained, and which forms the basis of chocolate.



Byttneria inodora.

1, A complete flower seen from above; the outer pentagon is the calyx, the auricled bodies are petals, and the five-rayed centre represents the five sterile stamens; 2, the calyx cut open, with the stamens attached to it; 3, a longitudinal section of a flower, showing the origin of the petals; 4, a petal; 5, a calyx seen from above, with the young fruit cut transversely, and the hooked hairs with which it is covered projecting from its sides; 6, a stamen; 7, the ovary.

The fruit of *Guazuma ulmifolia* is eaten by the Brazilians. Many of the species yield fibres which might be manufactured into cordage, as *Microlæna spectabilis* and *Abroma augustum*. [ABROMA.] In Madagascar the bark of *Dombeya spectabilis* is made into ropes. [DOMBEYA.]

BYTTNERIADS. [BYTTNERIACEÆ.]

C

CABBAGE. [BRASSICA.]

CABBAGE, BRAZIL. [CALADIUM.]

CABBAGE PALM. [ARECA.]

CABOTZ, a name for the Cusso or Kousso. [BRAYERA.]

CACHALOT. [CETACEA.]

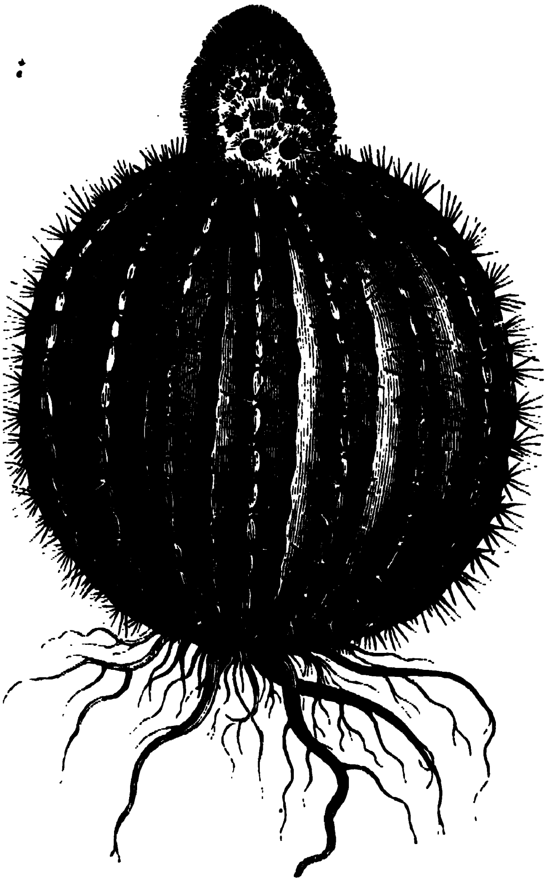
CACHOLONG. [OPAL.]

CACTACEÆ, or CACTEÆ, Indian Figs, the Cactus Tribe, a natural order of Exogenous plants.

The fructification of these plants consists of a calyx adhering to the ovary, with a border divided into an uncertain number of segments, which are arranged in several rows, the one overlapping the other, and the innermost gradually ceasing to be green and leafy, but acquiring the delicacy and colour of petals. The latter usually pass into sepals by insensible gradations, are very numerous, and often brilliantly coloured. The stamens originate in the orifice of the tube formed by the combination of the petals and sepals, are very numerous, and consist of delicate thread-shaped filaments terminated by small roundish anthers. The ovary, which, in consequence of its adhesion to the sepals, seems to occupy the place of the stalk of the flower, consists of a single cell lined with parietal placentæ covered over with minute ovules; its style is slender; the stigma is star-shaped and divided into as many narrow lobes as the ovary contains placentæ. The fruit is a succulent berry, marked at the end by a broad scar formed by the separation of the limb of the calyx: it contains a great quantity of seeds, which consist of nothing but a skin containing a succulent embryo slightly two-lobed at the upper end.

In natural affinity these plants have been considered allied to the Gooseberry Tribe (*Grossulaceæ*) on account of the great similarity in the structure of their fruit, and in the general production of spines upon their branches. Their relationship is probably far greater with *Mesembryaceæ* and the other epigynous orders of polypetalous dicotyledons.

The habit of *Cactaceæ* is remarkable. They have a very succulent stem in which the woody system is developed in but a small proportion compared to the whole mass. Usually the stem is angular or deeply channeled, occasionally it is destitute of both angles and channels, but in that case is mostly either much compressed as in *Opuntia*, or leafy as in *Epiphyllum*. Sometimes it is continuous from the base to the apex, but in many instances it is divided off into regular joints, each of which has a similar form varying with the species: in these instances however it is worthy of remark that as the stems advance in age the angles fill up, or the articulations disappear in consequence of the slow growth of the woody axis and the gradual development of the cellular substance; so that "at the end of a number of years, which vary according to the species, all the branches of *Cactaceæ*, however angular or compressed they originally may have been, become trunks that are either perfectly cylindrical or which have scarcely any visible angles. This metamorphosis is one of the causes which render it so difficult to identify species that have been described in their native localities from full-grown specimens with such as are cultivated in the gardens of Europe." The greater part of the species have stems which are more or less elongated, but in some they are spherical, as in the whole genera *Melocactus* and *Echinocactus*. Whatever may be the form of the stem, they usually bear upon their surface little tubercles which at an early age lose the leaves. Those organs however rapidly fall away, and are succeeded by tufts of hairs or spines hooked backward at the ends, and then the species have the appearance of being perfectly leafless.



Melocactus communis.

All the species are believed to be natives of America, whence however some of the Opuntias have been so long introduced to the Old World that they have here and there taken possession of the soil, and appear like aboriginal inhabitants. Such is the case on the volcanic soil of Ætna, and in various places on the shores of the Mediterranean; and this has led to the erroneous idea entertained by Sprengel and others, that the *Opuntia* of Theophrastus was the *Opuntia vulgaris* of modern botanists. The *Cactaceæ* are chiefly found in the tropical parts of America, a few species only escaping from those countries; as, for example, to the southern states of North America and to the highlands of Chili and Mendoza. They principally occur on hot dry rocks or plains where the commoner forms of vegetation could not exist, and may be considered one of the means which nature has provided for the support of man in regions where neither food nor water can be procured. Their stems are filled with an abundant insipid wholesome fluid, and their fruit is succulent and in many cases superior to that of European gooseberries. In the fevers of their native countries they are freely administered as a cooling drink, and being bruised, they are esteemed a valuable means of curing ulcers. For the sake of such their uses, because of their rapid growth, and especially on account of the numerous spines with which they are armed, the Opuntias or Tunas, as the Spanish Americans call them, are much planted round houses as fences, which neither man nor animals can easily break through. They are not unfrequent in the dry forest-lands of Brazil, but are said never to occur in the damper parts of the country. In stature they vary greatly, many of them having small creeping stems, which seem to crawl upon the ground among the dead branches of the surrounding trees, with whose gray colour their deep green shoots form a singular contrast. Others rise like candelabra with many angular ascending arms, while a few elevate their tall and deeply-channeled leafless trunks far above the stunted vegetation of the sterile regions they inhabit, reaching sometimes the height of 30 or 40 feet.

To enable them to endure the excessive drought to which they are naturally exposed they are furnished with an unusually tough skin, the evaporating pores or stomates of which are few in number and very often to all appearance merely rudimentary. This contrivance prevents their losing the scanty moisture which they collect from the burning soil, and enables them to sustain the full ardour of the brightest equinoctial sun without inconvenience; in this respect resembling the succulent fruits of Europe, such as the plum, the grape, the peach, &c., which by the absence of stomates from their tough skin are equally enabled to bear the powerful action of the bright sun that is necessary for their maturation.

These facts teach us what the points are that it is most necessary to attend to in the cultivation of the numerous species which now abound in our gardens. Their skin is so formed that perspiration takes place very slowly through it, unless under the influence of powerful stimulants and when in a young state. It is therefore obvious that they should be sparingly watered or not watered at all during a considerable period of the year. Dry as the places usually are in which *Cacti* naturally grow, they are periodically visited by heavy rains, which, combined with a bright light and a high temperature, force into activity even the sluggish vital powers of such plants as those under consideration. At such a time the annual growth of a *Cactus* takes place, secretions which enable the species subsequently to form its flowers are deposited, and a general impulse is given to all the torpid energies of its constitution. But by degrees the rains moderate and finally cease; the young cuticle which at its first formation perspired freely becomes thicker and tougher, and impermeable to moisture; what food has been obtained during the short period of growth is securely inclosed within the recesses of the stem; and when the air and earth become dry the plant is provided with the means of enduring another long period of fasting and inactivity. With the fall of rain the heat moderates, but the light to which the *Cacti* are exposed is but little if at all diminished; so that the assimilation and alteration of the food contained within the stem keeps continually going on, however slowly. It is by following this natural course of events that gardeners have succeeded in bringing their *Cacti* to that extraordinary state of beauty for which they are now conspicuous; it is by attending practically to such points in the habits of the species that we obtain the myriads of large, brilliant, red, or blush or snow-white blossoms that form the glory of our green-houses in the spring. A *Cactus* is placed in a damp stove, exposed to all the light that can be collected without being concentrated, and it begins to grow: it is then watered, at first gently, afterwards copiously with water holding a quantity of organisable matter (manure) in solution; this practice is continued for three months, when the quantity of moisture is diminished and the temperature is lowered, but exposure to light is still attended to, till at last the plant sinks to rest. In this state it is kept till the season for again forcing it into growth shall have returned, when it is subjected to a repetition of the same treatment as before.

If the *Cactaceæ* are to be propagated, their branches or joints, if they have any, are cut off, a little dried, and then placed in a hot and damp place, when they strike root immediately. Among the practical consequences, De Candolle observes, that result from the facility with which they are thus multiplied, is one which deserves to be noticed on account of its importance, namely, the manner in which the *Opuntia* is employed to fertilise the old lavas at the foot of Ætna. As soon as a fissure is perceived, a branch or joint of an *Opuntia* is stuck in: the latter pushes out roots, which are nourished by the rain that collects round them, or by whatever dust or remains of organic matter may have collected into a little soil: these roots, once developed, insinuate themselves into the most minute crevices, expand, and finally break up the lava into mere fragments. *Opuntias* treated in this manner produce a great deal of fruit, which is sold as a refreshing food throughout all the towns of Sicily.

Where however the species have neither branches nor joints, as is the case with some of the species of *Melocactus* and *Echinocactus*, a different mode of propagation is had recourse to: it is then necessary to compel them to branch by artificial means. Each of the numerous tufts of spines that occupy the ridges of their stems is a bud, and is capable of being forced into a branch, if by any means the general tendency to grow at the upper extremity only is checked. This is effected either by burning the apex of the plant with a broad flat iron, or by cutting the plant across below the top, in either of which cases several of the spiny buds will gradually swell and develop themselves as little branches, which being broken off will strike root and become new plants.

It is on species of the *Cactaceæ* that the cochineal insect feeds. Of these the most common are the three following:—*Opuntia Tuna*, which seems the most employed in Peru; *O. Hernandezii*, which is the most celebrated in Mexico; and *O. cochenillifera*, the native province of which is somewhat doubtful.

CACTUS, a genus of plants, the type of the natural order *Cactaceæ*.

The species are numerous, and have the general characters of the order. [CACTACEÆ.]

CADDICE, CADDIS-WORM, or CAD-BAIT, the common name for the larvæ of the species of *Phryganea*, which reside in the water, in cases which they form of various substances, such as bits of stick, grains of sand, small stones, shells, &c., which are held together by a silken thread secreted in their bodies in the same manner as in the silk-worm. The case acts as a protection to the larva, and it is capable of drawing in its head or putting it out, according to circumstances.

CADMIUM. [GREENOCKITE.]

CÆSALPINIA, a genus of plants belonging to the tribe *Cassieæ*, of the natural order *Leguminosæ*, and especially distinguished by the lowermost of its sepals being arched, the uppermost of its stalked petals being the shortest, its stamens all perfect with shaggy bases, and the fruit a compressed bivalved pod. The species are trees or shrubs, found in both the East and West Indies, with showy yellow flowers, abruptly pinnated leaves, and stems which are usually more or less prickly. The Brazil-Wood of commerce is said to be furnished by two of its species.

One of these, *C. Brasiliensis*, is a West Indian rather than a Brazilian tree, without prickles, downy flower-stalks, panicled flowers, smooth obtuse oblong leaflets. The other, *C. echinata*, which is really a Brazilian plant, is a prickly tree, with yellow and red blossoms, smelling deliciously like lilies of the valley, prickly pods, and oval blunt leaflets. Both these species undoubtedly yield a red wood, but it is by no means clear that they exclusively furnish the Brazil-Wood of commerce, as is commonly stated. According to Dr. Bancroft, this article is obtained from a tree with a large crooked knotty stem, the bark of which is so thick that a tree as large as a man's body with the bark, will not be so thick as the leg when peeled; and he calls this species *C. Brasiletto*, a name unknown to botanists: he however states that it is called by the natives Ibiripitanga. Now, that is the name given by Marcgraaf to the *C. echinata*, but this author says nothing about the peculiarity in the bark. One authority however ascribes a particularly thick alburnum to *C. echinata*, but says nothing of the bark. Malte-Brun says there are three kinds of Mirim, or Brazil-Wood found in Brazil; but he includes with them the *C. Brasiliensis*, which there is no good authority for considering a native of that country. Fée again refers the sappan wood of the East Indies (*Cæsalpinia Sappan*) to one of the Brazil-Woods of the merchants. Upon the whole it appears that we have no good testimony as to what the tree is that yields it; but it is probable that it is the produce of many species, and possibly of more than one genus, for De Candolle and Sprengel doubt whether the *Cæsalpinia echinata* is not rather a *Guilandina*. The best Brazil-Wood is said to come from Pernambuco, where it is called Páo da Rainha, or Queen's Wood, on account of its being a royal monopoly. The Bukkum or Sappan Wood of commerce is yielded by *C. Sappan*. A substance known in the markets under the name of Dividivi or Libidibi has lately become important on account of the tannin it contains. It is the fruit or pods of *C. coriaria*. They are not used in medicine, but in dyeing and tanning.

CAFFER-BREAD. [ENCEPHALARTOS.]

CAKILE, a genus of plants belonging to the natural order *Cruciferæ*, to the sub-order *Lomentaceæ*, and the tribe *Cakilineæ*. In addition to the accumbent cotyledons of the tribe, it has an angular pouch composed of two 1-seeded indehiscent joints; the upper joint deciduous, with an erect seed, the lower one persistent, seedless, or with a pendent seed. The species are annual branched herbs, smooth, fleshy, glaucous, with pinnatifid or toothed leaves; racemes of flowers opposite the leaves, and terminal with filiform bractless pedicles.

C. maritima, Purple Sea-Rocket, has the joints of the pouch 2-edged, the upper one with two teeth at the base, the leaves fleshy, pinnatifid, somewhat toothed. The flowers are of a purplish colour. It is a native of Europe, along the sea-coast from Sweden and Lapland to Gibraltar; it is also found on both sides of the Mediterranean. It is a native of Great Britain, on the sea-coast. This plant had at one time a reputation as a cathartic, but it is not employed at the present day. There are three other species of *Cakile*, named—*C. Ægyptiaca*, *C. Americana*, *C. equalis*. They are all pretty annuals, and may be easily cultivated. The seeds may be sown in spring or autumn, and they should be treated as other hardy annuals.

(Babington, *Manual*; Don, *Gardener's Dictionary*.)

CALABASH, a name given in the West Indies to the fruit of the tree called *Crescentia Cujete* by botanists. [CRESCENTIA.]

CALA'DIUM, a genus of plants belonging to the natural order *Aroideæ*, and to the tribe *Caladieæ*. The flowers are monœcious, and the calyx and corolla are absent; the male flowers have many-celled peltate anthers, disposed in a spike at the end of the spadix; the female flowers have the ovaries inserted at the base of the spadix, no style; the fruit is a 1-celled berry with many seeds. A great number of species of this genus have been described. They are frequently cultivated in this country for the sake of their spotted stems and neat green leaves, which are rarely disfigured by any of the accidents which affect other stove-plants. They have the same general appearance as the species of *Arum*, and also resemble them in physical and chemical properties.

C. Seguinum, Dumb-Cane, is a caulescent suberect plant with oblong cuspidate leaves, and the spadix shorter than the oblong spathe. This plant is a native of South America and the West Indies. It grows to a height of five or six feet. It secretes an acrid poison, so that when any part of the plant is chewed the tongue swells and the power of speech is lost. It is on this account called 'Dumb-Cane.' Sir William Hooker, in his 'Exotic Flora,' relates the case of a gardener who incautiously bit a piece of Dumb-Cane: "His tongue swelled to such a degree that he could not move it; he became utterly incapable of speaking, and was confined to the house for some days in the most excruciating torments." The juice is stated to impart an indelible stain to linen. Notwithstanding its poisonous nature, P. Browne says that, in common with the *Arum ovatum*, its stalk is used to bring sugar to a good grain when it is too viscid, and cannot be made to granulate with lime alone. In the districts where it grows the natives use a decoction of the stem as a bath and fomentation in dropsy, and the rootstock is used in obstinate constipation and in long-standing gout. The negroes use it as an anti-aphrodisiac.

C. sagittifolium, Brazil Cabbage, is stemless, with sagittate acuminate leaves, the spadix shorter than the spathe, which is ovate-cucullate. This plant is a native of the West Indies, and is called by the French Chou-de-Bresil, and by the Germans Essbar Arum. In appearance it resembles *Arum colocaria*, and is used for the same purposes. Both the leaves and rootstock of this plant are eaten. The leaves are boiled and eaten as coleworts; the rootstock is not considered so great a delicacy as the leaves. Of all the eatable *Aroideæ*, this appears to be the most extensively cultivated. It is found in the East and West Indies, in China, Japan, New Zealand, and the South Sea Islands. When raw the rootstock contains a certain amount of the poisonous secretion of the family, and like the potato has an acrid unpleasant flavour, which entirely disappears in cooking. The leaves are very soft and glaucous, from being covered with a fine silky hair, and in many places are used instead of plates and dishes.

C. esculentum resembles the last: its leaves are peltate-cordate, and its spathe ovate-lanceolate. It is also a native of South America, and is cultivated on account of the starch contained in its rootstock. It possesses properties similar to the last.

C. arborescens is a poisonous species, though not so virulent as the Dumb-Cane. Merat says that it was formerly used for wetting the mouths of negroes as a punishment for slight misdemeanours.

(Loudon, *Cyclopædia of Plants*; Lindley, *Natural System*; Burnett, *Outlines of Botany*; Bischoff, *Medicinisch-Pharmaceutische Botanik*.)

CALAMINE. [ZINC.]

CALAMINT. [CALAMINTHA.]

CALAMINTHA, a genus of plants belonging to the natural order *Lamiaceæ*, and the tribe *Satureiineæ*. It has the apices of the stamens connivent under the upper lip of the corolla; the anther-cells at length divergent, connective, subtriangular; the upper lip of the corolla straight, nearly flat, the lower patent trifid; the calyx 2-lipped and 10-13-nerved, throat hairy; the flowers whorled, axillary or spiked. This genus was constituted by Moench, and contains several species which were placed under *Thymus* and *Clinopodium* by Smith, in *Melissa* by Bentham, and one in *Acinos* by Hooker. Koch in his 'Flora Germanica' follows Moench, and also Babington in his 'Manual of British Botany.' There are four species of this genus, common and well-known plants in Great Britain.

C. Nepeta, Lesser Calamint, Cat-Mint, Balm or Field-Balm, has leaves ovate, obtuse, serrated, pale beneath, shortly stalked; calyx subcampanulate, obscurely 2-lipped, teeth all nearly the same shape, the upper ones slightly shorter; nuts roundish, almost smooth; cymes dichotomous, many-flowered. This is not a common plant, and is found on dry banks. It has a strong aromatic smell not unlike that of penny-royal, and a pungent taste. Cats are said to be fond of the smell, and hence its name cat-mint. An infusion of the leaves is recommended as a tonic and stimulant in flatulence and colic. This and the other species possess the volatile oil which is found in the whole order, and hence they all have a more or less powerful medicinal action.

C. officinalis (*Thymus Calamintha*, Smith; *Melissa Calamintha*, Bentham), Mountain-Balm, Common Calamint, has broadly ovate, rather acute, slightly serrated leaves, green on both sides, seated on longish stalks; the calyx tubular, ventricose in front, distinctly 2-lipped, teeth of the upper lip triangular, of the lower twice as long, and subulate; nuts roundish, covered with impressed dots; cymes scarcely dichotomous, few-flowered.

C. Acinos (*Acinos vulgaris*, Persoon; *Acinos thymoides*, Moench), Basil-Balm, or Basil-Thyme, has ovate subserrate acute leaves with revolute margins; tubular gibbous calyx distinctly 2-lipped, the upper lip with short triangular teeth, the lower one with subulate teeth, all converging in fruit. It is found in dry gravelly places, and in corn-fields throughout Europe.

C. Clinopodium (*Clinopodium vulgare*, Smith), Wild Basil, Bed-Foot, has ovate obtuse leaves, rounded below, slightly crenate; whorls equal, many-flowered; bracts setaceous, as long as the calyx. Common in dry bushy places, in Europe; it is also found in America, but has probably been introduced there.

(Babington, *Manual*; Bentham, *Labiatarum Genera et Species*.)

CALAMITES, one of the most frequent and characteristic genera of fossil plants. It is found abundantly, but not exclusively, in the Carboniferous system of strata, and generally in the sandstones and shales which alternate with coal. *Calamites Suckovii* occurs in most European and American Coal-Fields. *Calamites arenaceus* occurs in the Bunter Sandstein. We have found traces of a *Calamites* in the Red Marl series of Worcestershire. [COAL PLANTS.]

CALAMOPHILUS, a genus of Birds belonging to the family *Paridæ* and the tribe *Insessores*, sub-tribe *Dentirostres*. *C. biarmicus* of Yarrell is the *Parus biarmicus* of Pennant and other writers. This bird is common in Great Britain, and is known by the name of the Bearded Tit. [PARIDÆ.] (Yarrell, *British Birds*.)

CALAMO'PORA, the generic title applied by Goldfuss to many Palæozoic Corals, for some of which Lamarck employed the name of *Favosites*.

CA'LAMUS, a genus of Palms the different species of which yield the Rattan Canes of commerce. Although a genuine palm, yet from the slender stems and general habit, it has more the look of some tall grass, and has been considered as one of the links in the chain of organisation which connect the Grasses with the Palms. Blume gives the following account of the flowers and fruit:—Polygamous-diœcious, or diœcious; spathes several, incomplete; flowers sessile, in spikes; calyx 3-toothed or trifid; petals 3, united at the base; stamens 6; filaments subulate, connected at the base into a cup; anthers arrow-shaped, fixed by the back. The rudiment of an ovary:—female: ovary 3-celled, surrounded by a staminiferous cup, which is usually sterile; style scarcely any; stigmas 3, distinct or combined; berry protected by scales overlapping each other downwards, 1-seeded; seed surrounded by a succulent flesh; albumen uneven in the circumference, even in the inside, or near even in the circumference and ruminated internally; embryo at the base; leaves pinnated.

The species are principally found in the hotter parts of the East Indies, where they grow in the forests, climbing over trees and bushes to a greater extent than any other known plants. The stem of *Calamus verus* is described as being 100 feet long, that of *C. oblongus* 300 to 400 feet, of *C. rudentum* upwards of 500 feet, and of *C. extensus* as much as 600 feet; Rumphius even states that one kind attains the extraordinary length of 1200 feet (vol. v. 100). It is closely covered over by the tubular bases of the leaves, through which it is drawn by the cane-gatherers when green; afterwards it is dried in the sun, and then is ready for market. These canes are extensively used for the sake of the hard flinty coating of their stems, which are readily split into strips, from which the bottoms of chairs and similar articles are manufactured. It is not possible to say from what particular species the canes of the shops are obtained, it being probable that many are gathered indiscriminately; *C. Rotang* has however been said to furnish the stouter, and *C. Scipionum* the slenderer sorts. The flesh that surrounds the seeds of this genus is a delicate article of food; limpid water flows from the stems when cut through; and finally the young shoots of some of them, while still tender, are roasted or boiled, chopped small, and being fried with pepper and gravy, are said to furnish a very delicate dish.

It is not a little remarkable that notwithstanding the polished surface of the stem, almost all the other parts except the fruit should be furnished with stiff hairs and even prickles. The prickles are usually hooked backwards to enable the plants to raise themselves upon the trees among which they grow in their native forests; and to assist them in this operation the terminal pinnæ of the pinnated leaves are shortened, hardened, and also hooked backwards. Several species are copiously described in Rumphius's 'Herbarium Amboinense,' (vol. v.) under the name of Palmijuncus. Dragon's Blood or Djurnang, is the produce of a species of *Calamus*. Those which chiefly yield it are the *C. petræus* (Lour.), *C. rudentum* (Lour.), *C. verus* (Lour.), and *C. Draco* (Willd.), of which the last three were by Linnæus reckoned mere varieties of the *C. Rotang* (Linn.). They are natives only of Hindustan, Cochin China, and the Moluccas. The ripe fruits are covered with a reddish-brown dry resinous substance, which is the Dragon's Blood. In this state they are collected, and allowed to remain in rice-mills till the resin drops off. The resin is afterwards melted, either by the natural warmth of the air or by artificial heat, and then moulded into the different forms in which it occurs in commerce. Another mode of obtaining it is as follows:—The ripe fruits are shaken in bags, and the resin so obtained is formed into pieces about the size of a bean, which are then wrapped up in leaves; this kind is much prised in the East Indies. A second sort is procured by throwing together the fruits after they have been treated in the foregoing manner, melting them in the sun or with a slow fire, and collecting what exudes, which is then formed into small four-cornered cakes. A third sort is obtained from what remains after the two foregoing processes, being run out and formed into round cakes, which contain hard portions of the fruit. According to other accounts, the finest sort is procured by exposing the fruits to the vapour of boiling water, and scraping off the soft resin as it exudes.

CALA'NDRA, a genus of Coleopterous Insects belonging to the section *Rhynchophora*, and family *Curculionidæ*. It has the following characters:—Antennæ eight-jointed, geniculated, and inserted behind the middle of the rostrum (that is, towards the base); the six joints following the basal one are short, the apical joint forms a large knob, generally somewhat hatchet-shaped, having the apex soft and spongy; rostrum long, and slightly bent downwards; thorax rather long and depressed, narrower in front than behind; body somewhat depressed and pointed at the apex; elytra shorter than the abdomen; legs short, tibiæ armed with a spine; tarsi four-jointed, the penultimate joint bilobed.

The well-known Corn-Weevil (*C. granaria*), which commits so much havock in our granaries, belongs to this genus: it is about one-sixth of an inch long, or rather less; of a pitchy-red colour; the thorax is coarsely punctured, and the wing-cases are deeply striated; the striæ are minutely punctured; the legs and antennæ are red.

This little insect bores a hole into the grain with its proboscis, in which an egg is deposited; the egg turns to a little grub or larva, which devours the whole of the inside of the grain, leaving the husk entire. This quantity of food is just sufficient to mature the grub: it then turns to the pupa, and afterwards to the weevil, which easily breaks through the husk, and is then at liberty to proceed as its parent did. When wheat is suspected to contain these little weevils or their grubs, that which is affected may be easily discovered by throwing the whole into water; that which is good will sink, while the rest will float.

Another species of *Calandra* (*C. Oryzæ*, Linn.) closely resembling the corn-weevil, from which however it may be distinguished by its having four red spots on its elytra, attacks the rice grain in the same way as the one above mentioned does that of the wheat.

C. Palmarum, a large species, being about an inch and a half in length, lives during its larva state on the pith of the palms of South America. It is of a dull, velvet-like black, and has the proboscis furnished with a brush of black hairs on the upper part near the apex.

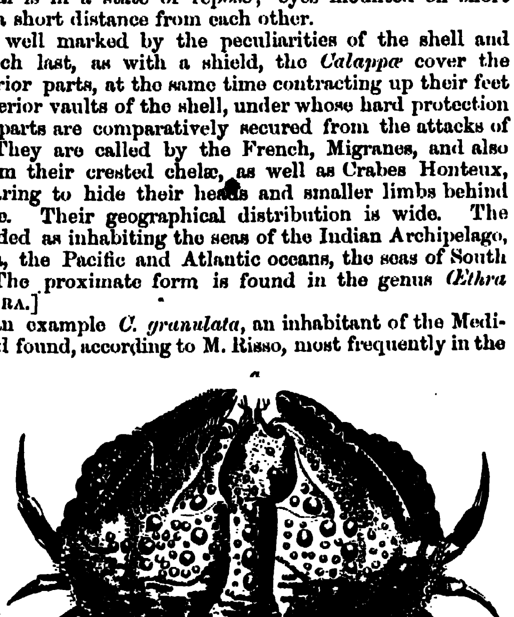
The larva of this species, which is called by the natives the Ver Palmiste, is considered by them a great dainty.

CALAPPA, a genus of Brachyurous Decapod *Crustacea*, separated by Fabricius, and formerly embracing the genus *Hepatus* of Latreille, though now restricted to the following form.

Generic Character:—External and internal antennæ similar to those of the Crab (*Cancer*) properly so called, third articulation of the pedi[illegible]i (pieds-mâchoires extérieurs) terminated somewhat like a pointed hook; chelæ equal, very large, compressed, with their upper edge, which is notched or crested, very much elevated, and fitting exactly to the external border of the shell or carapace, so as to cover the entire region of the mouth; the rest of the feet short and simple; carapace short, convex, wider posteriorly than anteriorly, and forming behind a vaulted shield, under which the posterior legs are hidden when the animal is in a state of repose; eyes mounted on short pedicles, and at a short distance from each other.

The genus is well marked by the peculiarities of the shell and chelæ, with which last, as with a shield, the *Calappæ* cover the mouth and anterior parts, at the same time contracting up their feet beneath the posterior vaults of the shell, under whose hard protection their vulnerable parts are comparatively secured from the attacks of their enemies. They are called by the French, Migranes, and also Coqs de Mer, from their crested chelæ, as well as Crabes Honteux, from their appearing to hide their heads and smaller limbs behind their large chelæ. Their geographical distribution is wide. The species are recorded as inhabiting the seas of the Indian Archipelago, and of Australia, the Pacific and Atlantic oceans, the seas of South America, &c. The proximate form is found in the genus *Œthra* of Leach. [ŒTHRA.]

We select as an example *C. granulata*, an inhabitant of the Mediterranean Sea, and found, according to M. Risso, most frequently in the fissures of rocks near Nice, where these crabs reach to the depth of 90 feet. The same zoologist says, that the females deposit their eggs in summer; and that there is a variety whose shell is six-toothed posteriorly, and whose general colour is pale rose, with whitish feet and brown nails.



Calappa granulata.

a, The Crab with the limbs exserted; b, the right chela.

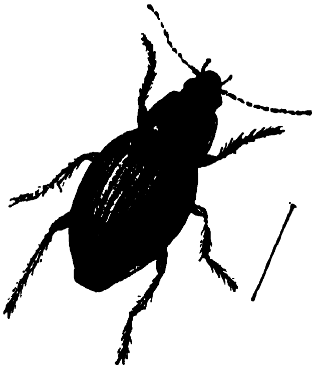
The following is Desmarest's description of *C. granulata*:—Carapace verrucose, marked with four longitudinal sutures, and having on each side before it begins to dilate seven teeth, three short and obtuse, and four more strong and pointed upon the borders of the enlarged part, with two other smaller ones entirely behind;

front bidentated; colour, that of flesh sprinkled with spots of carmine red; length 2¼ inches; breadth 3 inches, 6 lines, French.

CALATHI′DIUM, a modern name for the flower-head of the plants called *Compositæ*, the common Calyx of Linnæus. It consists of a flattish or conical cellular disk, called the Receptacle, upon which a number of small flowers are very compactly arranged; and its surface is either naked and even, except so far as the scars left by the attachment of the flowers render it otherwise, or covered with hairs, bristles, or scales, named Paleæ. Its margin is uniformly furnished with one or more rows of small leaves or scales which inclose the flowers as within a cup. The form, number, texture, and proportions of these scales often afford good generic characters. In reality, a Calathidium is a short spike of inflorescence, the receptacle being the depressed axis, its paleæ bracts, and the external scales being other bracts in a more perfect state. The Daisy, the Dandelion, and the Sunflower, offer illustrations of this form of inflorescence.

CA′LATHUS, a genus of Coleopterous Insects belonging to the section *Geodephaga* and family *Harpalidæ*. It has the following characters:—Body elongate, somewhat ovate, slightly pointed posteriorly; thorax wider behind than before; anterior tarsi with the three basal joints dilated in the males; claws dentate beneath; palpi with the terminal joint almost cylindrical, and truncated; labrum transverse, and slightly emarginated anteriorly.

Upwards of twenty species of this genus have been discovered, almost all of which are European. Their general colouring is black or brown; one or two metallic-coloured species however are known. In England eight species have been enumerated, most of which are common. Four species may be found under stones and rubbish in the neighbourhood of London; of these *C. cisteloides* is exceedingly common, frequently being met with in pathways, &c.; it is about half an inch long, and of a black colour; the antennæ are pitchy black, with the basal joint red; the legs are black, and in some specimens red. The wood-cut here given of *C. latus* will enable the reader to form an idea of their general appearance; it is a very rare species in this country, and differs chiefly from the one above mentioned in its greater width, and the thorax having the lateral margins of a reddish hue.



Calathus latus.

CALCAIRE GROSSIER, the coarse calcareous building-stone of Paris, which, geologically speaking, is coeval with the blue clay of the basin of London, and contains many identical shells. These constitute the types of the Eocene Tertiary series of Mr. Lyell.

CA′LCAR, a genus of Coleopterous Insects belonging to the section *Heteromera* and family *Tenebrionidæ*. This genus is distinguished from the allied genera (*Hypophlæus*, *Apis*, &c.) by having the body linear, the head emarginated anteriorly, and the three or four terminal joints of the antennæ nearly globular; the thorax is longer than broad, truncated anteriorly and posteriorly, and of nearly equal width throughout.

CALCAR, or Spur, in flowers, is a hollow projection from the base of a petal, and has usually a conical figure. It was called Nectary by Linnæus, but it rarely secretes honey. Its use is unknown. The spurs of some of the *Orchidaceæ* are several inches long, and many times longer than the flowers to which they belong, hanging down like vegetable tails.

CALCAREOUS SPAR. Under this term it is usual to include only those varieties of Carbonate of Lime which occur in distinct individual crystals of the rhombohedral system, the name never being used to denote Arragonite, or any crystals of carbonate of lime belonging to the prismatic system; nor is it usual to apply it to those more or less crystalline limestones of which marble is the purest variety, where each crystal is so embedded in the mass as to have lost all individuality. In a word, these rocks are of such importance and interest that they do not admit of our treating them as a mineralogical variety, but as masses formed by the aggregation of numerous crystals of it. These are noticed therefore under the heads Limestone and Marble, while we shall here confine ourselves to the individual crystals of which the others are composed.

This substance presents us with one of the most interesting objects which can engage the attention of the mineralogist, not only on account of the important part it plays in the geological structure of the earth, being frequently almost the sole ingredient of beds of rock of great thickness and extent, produced at every geological epoch, but also from the beauty and diversity of its crystalline forms, and from the peculiarity of several of its physical properties. The study and a correct knowledge of this mineral species have also become of still greater importance since the discovery of the principles of isomorphism, by which it is shown that it is the most perfectly developed individual of a very large class of the mineral salts of carbonic acid, of which it may consequently be considered the type.

If any crystal of calcspar, whatever its form, be carefully examined, an appearance indicating a tendency in its substance to break or split in the direction of three planes symmetrically related to the form may be perceived, and by a gentle blow the whole is readily reduced to fragments, each of which may with a little care be brought to the form of the rhombohedron represented in *fig.* 2, the faces of which are parallel to the three planes of cleavage above mentioned. This, in the language of Haüy, is the primitive form of calcspar, and represents, according to his theory, the shape of the ultimate molecules or atoms of carbonate of lime, by the aggregation of which, according to certain laws, its various crystals are produced. Although this rhombohedron occurs rarely or never as an unbroken crystal of pure carbonate of lime, it is nevertheless the most convenient ground-form, to the axis of which the faces of all other crystals of this substance may be referred, and it is therefore selected for that purpose. These forms, although far exceeding in number those observed in any other mineral species, are however (omitting the regular hexagonal prism, *c*, and its terminal faces, *o*, *fig.* 6) but of two kinds, being either rhombohedrons, of which varieties are represented in *figs.* 1, 2, 3, and 4, or scalinohedrons, one of the most common of which is seen in *fig* 5. Their relations to each other and their combinations have been developed principally by Haüy, Bournon, and Monteiro, by whom no less than 30 different rhom-

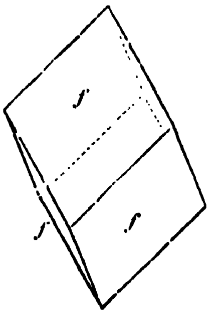

Fig. 4.

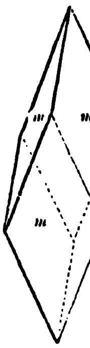

Fig. 5.

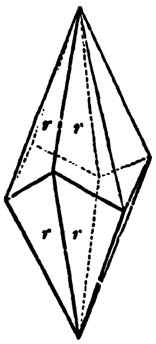

Fig. 6.

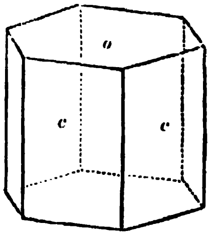

Fig. 7.

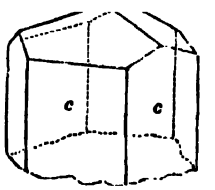

Fig. 8.

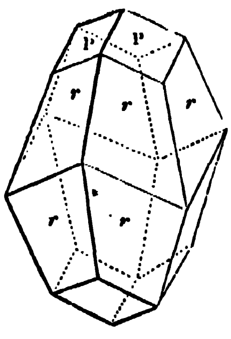


bohedrons and 50 scalinohedrons have been distinguished. As might naturally be expected, the combinations resulting from so large a number of simple forms are exceedingly great, and Bournou, who has written a treatise of three thick volumes on this mineral and Arragonite, has distinguished no less than 700 varieties of form. Of these 154 are described in the large work by Haüy, accompanied by very accurate drawings of each.

A general knowledge of the crystalline form of this mineral may however be easily obtained by acquiring a knowledge of the relation of the faces of the five simple forms and the hexagonal prism referred to above; as in almost all the more ordinary combinations the general feature of the crystal is produced by one of these. The *fig.* 2, which, as has been already stated, is considered as the ground-form, is a rhombohedron, the faces of which are inclined to each other in the terminal edges at 105° 5′. This form, though exceedingly rare in pure calcspar, is however the prevailing crystal in the nearly allied species produced by the combinations of the carbonates of lime and magnesia, as will be seen by referring to the article DOLOMITE. In determining the relations of any form, the position of the planes of this rhombohedron in reference to the other parts must first be fixed, and this is readily accomplished in every case, owing to cleavage-planes running parallel to its faces. This being determined, all other rhombohedrons are at once divided into rhombohedrons of the first order, such as *fig.* 4, which have their faces situated as the faces of the ground-form, or into rhombohedrons of the second order, the faces of which are situated as the edges of the ground-form, as is the case with *figs.* 1 and 3.

The rhombohedron *fig.* 1, which may thus be seen to belong to the second order, is readily recognised by having its faces *g* making the same angle with the vertical axis A B (*fig.* 2) as the terminal edges of the ground-form, so that in a combination the terminal edge of the ground-form is truncated by the plane *g*. This rhombohedron, which is called the first obtuser, has the angles at the terminal edges 135° 57′, and has with the same breadth its vertical axis one-half that of the ground-form. It is one of the most common of the rhombohedrons, and is frequently found alone, but still more frequently in combination with the hexagonal prism, producing the form seen in *fig* 7. It occurs frequently at Andreasberg, in the Harz, and in the mines of Derbyshire.

The rhombohedron *fig.* 3 is also of the second order, and is called the first obtuser: its terminal edges correspond with the long diagonals of the faces of the ground-form, and therefore, with the same breadth, its vertical axis is double that of the other: the inclination of the faces at the terminal edges is 78° 51′. In combination with the ground-form, if the faces *f* predominate the form P appears as truncations of the terminal edges; if P predominates, the faces of *f* produce truncations of the six lateral angles, the edges of intersection being parallel to the inclined diagonals of P for two faces, and with the horizontal one for the third.

The rhombohedron *fig.* 4 bears to *fig.* 3 the same relation as this does to the ground-form, the terminal edges of the first corresponding with the inclined diagonal of the second: the inclination of the planes to each other in the terminal edges is 65° 50′.

Fig. 5 is one of the most common scalinohedrons, and is commonly known as the Dog's-Tooth Calcspar, and is found frequently in Derbyshire and other localities. It bears a close connection with the rhombohedrons P and *m*, having the lateral edges of the first and terminal edges of the latter, so that in combination with the first the form *fig.* 8 is produced, and with the second it forms a bevelment of the terminal edges: the inclinations of the faces in the terminal edges are respectively 104° 38′ and 144° 24′. This form frequently occurs as twins, formed by two crystals growing on each other, their principal or vertical axes being in the same right line, and the two crystals so situated that the obtuser terminal edges of the one abut on those of the other, and the acuter on the acuter.

This mineral may be recognised by its perfect cleavage parallel to the faces P: the specific gravity of the purest crystals is 2·721; and the hardness is in the scale of Mohs 3, being situated between gyps and fluor-spar. It is of itself colourless, but frequently occurs of various tints of yellow, green, red, brown, and even black, from the admixture of impurities. Its glance is vitreous, with the exception of the terminal face *o*, which generally presents a mother-of-pearl lustre. It is usually more or less translucent, and when transparent produces in a remarkable degree the double refraction of light: this property is best seen in the varieties obtained from Iceland, and hence known as Iceland-Spar, and occurs as the ground-form, being in fact merely broken fragments of other larger crystals.

The following are the names of the more common varieties of Calcareous Spar:—Iceland Spar, Satin Spar, Chalk, Rock Milk, Calcareous Tufa, Stalactites, Stalagmite, Limestone, Oolite, Pisolite, Argentine, Fontainbleau Limestone, White and Clouded Marbles, Statuary Marble, Compact Limestone, Stinkstone, Anthraconite, Plumbo-Calcite, Mineral Agaric, &c.

CALCEDONY. [AGATE.]

CA'LCEOLA, an extinct genus of *Brachiopoda*, which occurs in the Palæozoic Strata, and especially in the middle group. *Calceola sandalina* occurs in this position in the Eifel, and in South Devon.

CALCEOLA'RIA, a genus of very ornamental herbaceous or shrubby plants, belonging to the natural order *Scrophulariaceæ*. Its distinctive characters are principally, the flowers being diandrous, with a two-lipped corolla, the lower lip of which is much larger than the upper, and inflated so as to resemble a bag. All the species are South American, and are confined either to the western side of the Cordilleras, or to the southern extremity of the continent and its adjacent islands: in Chili and the mountainous parts of Peru they are so common as to give a peculiar appearance to the vegetation. Some of them are lowlanders; others inhabit the highest parts of the Andes in the districts just below the regions of lichens and mosses; and thus, if both their wide geographical distribution and the various elevations at which they occur are taken into account, they are exposed to every kind of climate between those of England and Barbary.

The greater part of the genus has yellow flowers, a few have purple ones, and here and there in nature species occur with the two colours intermixed, by the addition of spots of purple to the yellow ground-colour, the latter changing the former to a deep rich brown. By intermixing artificially the two colours natural to the genus a production of hybrid varieties has resulted, and some crosses of extraordinary beauty have been obtained, especially from *C. integrifolia*, *corymbosa*, *arachnoidea*, *Chiloensis*, *crenatiflora*, *viscosissima*, &c.

CALCITE. [CALCAREOUS SPAR.]

CALEDONITE. [LEAD.]

CALENDULA. [ALAUDA.]

CALE'NDULA, a genus of plants belonging to the natural order *Compositæ*, the sub-order *Corymbiferæ*, the tribe *Cynareæ*, the sub-tribe *Calendulaceæ*, the division *Calenduleæ*. It has an involucre of two rows with equal scales; the flowers of the ray ligulate, pistilliferous, fertile; the style divided at top into two stigmata; the flowers of the disk hermaphrodite, barren, the style undivided; the achenia unequal, curved, toothed, or muricated.

C. arvensis, Field-Marigold, has the achenia cymbiform, muricated, incurved, the outer ones lanceolate, subulate, muricated on the back. This plant is common on the continent of Europe, and is found in immense numbers in some of the vineyards of the Rhine.

C. officinalis, Common Marigold, has cymbiform achenia, all of them incurved, and muricated. This is the Souci du Jardin of the French, Gold-Blume of the Germans, and Furrancio of the Italians. Although common enough now in the gardens of Great Britain, and frequently found wild, it is not a native of these islands, and has been introduced from the south of Europe. This plant is a great favourite in gardens, and continues to blossom till the approach of winter. It is often grown in churchyards in this country, and in cemeteries on the Continent, but this practice does not appear to be connected with any superstition. There are several varieties of this plant found in gardens, as the orange-coloured, the lemon-coloured, and the double. It had formerly numerous virtues attributed to it, but independent of the bitterness of the tribe to which it belongs, and a rather more powerful volatile oil than is found in other species of the order, it possesses no active properties. The flowers are used in some parts of the country to give a yellow colour to cheese. In the Clock of Flora of Linnæus, it is said to open its flowers at nine in the morning and to close them at three in the afternoon. *C. pluvialis* has been named from its flowers closing at the approach of rain. The petals of these plants are sometimes employed to adulterate saffron.

(Loudon, *Encyclopædia of Plants*; Koch, *Flora Germanica*.)

CALIDRIS, a genus of Birds belonging to the order *Grallatores* and the family *Charadriidæ*. It has the following characters:—Beak as long as the head, straight, slender, flexible, compressed at the base, with the point dilated and smooth; nostrils basal, lateral, narrow, longitudinally cleft in the basal furrow, which extends to the smooth point of the beak; wings of moderate length, pointed, the first quill-feather the longest; legs of mean length, naked above the tarsal joint; feet with three toes, all directed forwards, with a very small connecting membrane at their base. Gould, in his 'Birds of Europe,' regards the Knot (*Tringa canutus*) as a species of *Calidris*. With this exception the only British bird which is a species of this genus is *C. arenaria*, the Sanderling. It is an inhabitant of most of the shores of Great Britain and Ireland. It obtains its food by probing the moist sands of the sea-shores, from which it obtains minute *Mollusca*, shrimps, annelides, &c. It visits the shores of Sweden, and is stated to breed still farther north. Sir John Richardson says it breeds on the coasts of Hudson's Bay. It does not appear to breed in the British Islands. (Yarrell, *British Birds*.)

CALI'GUS, a genus of Entomostracous *Crustacea*, separated by Müller, in which Latreille and Lamarck include the genus *Pandarus* of Leach, but which Desmarest places under the fourth sub-division or race of *Pœcilopoda*: namely, those which have fourteen feet, of which the six anterior are unguiculated, the fifth pair being bifid with the last joints fringed with fine hairs in the form of cilia.

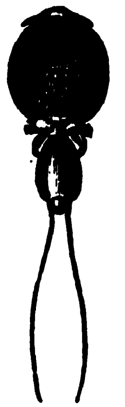
It has the body depressed, having its anterior portion covered by a membranous shell in the form of a shield. narrowed posteriorly. Abdomen narrower, of an elongated oval or nearly square shape, and terminated by two elongated antennæ-like processes, cylindrical and simple. There are two small conical antennæ situated on the anterior border of the head, and directed laterally, and at the internal base of these are placed the two distant eyes. Beneath the head there is an obtuse beak.

Caligus, together with *Argulus*, and other of its congeners of the family *Siphonostomata*, are commonly known among the fishermen as Fish-Lice. But *Caligus* is without the cupping-glass-like suckers, by which *Argulus* adheres to its slippery supporters; and the hooks of the anterior pairs of feet are the principal organs by which the former holds on to the fish. [ARGULUS.]

Argulus and *Caligus* are now usually regarded as types of distinct families *Argulidæ* and *Caligidæ*. *Argulus* is the only genus in the family *Argulidæ*. With *Caligidæ* are included the following British genera, *Lepeopthirus*, *Chalimus*, *Trebius*.

Dr. Baird, in his 'History of the British Entomostracous Crustacea,' describes four species of *Caligus* as natives of Great Britain.

C. Mülleri is found parasitic upon the Cod (*Morrhua valgaris*) the Brill or Brett (*Rhombus vulgaris*) and upon several other fishes. The following description is from Baird :—



Caligus Mülleri.
View of back.

Female.—Carapace oval, rather longer than broad, narrower at upper extremity; frontal plates of considerable size, notched in the centre; lemules well developed; antennæ of considerable size; basal joint large. Thorax shorter than the carapace, about half the size; penultimate joint very small, of an elongate diamond shape; last joint nearly quadrilateral, and lobed at the posterior extremity. On each lobe there are two very small tubercles, each of which gives off two short setæ. Abdomen very short and rounded, broader than long; caudal plates terminated by three tolerably-long plumose setæ; internal fork with simple short obtuse branches; second pair of foot-jaws very long, the last joint being narrow, long, and terminated by two curved claws, one longer than the other; fourth pair of legs stout, the first joint broad and thick, the last ending in one long stout curved claw, which is serrated on its inner edge, and two short ones; oviferous tubes of considerable length.

Male.—In the male the last joint of thorax is considerably smaller than in the female and more rounded; the lobes much sharper, and terminated by the same tubercles, but of a larger size. Abdomen about two-thirds the size of the last joint of thorax; second pair of foot-jaws large.

C. diaphanus is found on the turbot, the gurnard, the mackerel, the plaice, the holibut, and other fish.

C. rapax has been taken on the gurnard, Lough Neagh trout, brill, whiting, dory, and common dab.

C. centrodonti, has been found on the fins and tail of the common Sea-Bream (*Pagellus centrodontus*) alone.

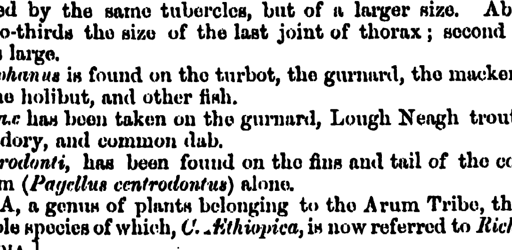
CALLA, a genus of plants belonging to the Arum Tribe, the most remarkable species of which, *C. Æthiopica*, is now referred to *Richardia*. [RICHARDIA.]

CALLEI'DA, a genus of Coleopterous Insects belonging to the section *Truncatipennes* and the family *Brachinidæ*.

This group was separated from the genus *Tarus* of authors, by Dejean, and is chiefly distinguished by the species having the penultimate joint of the tarsi bilobed.

Upwards of twenty species of this genus are enumerated in Dejean's catalogue, most of which are of brilliant metallic colouring, and inhabit the hottest climates, in both of which respects they likewise differ from the typical species of *Tarus*.

CALLIANASSA, a genus of Macrourous Decapod *Crustacea*, the chelæ of which are very unequal both in form and in their proportions. The carpus of the largest chela is transversal, and forms a common body with the claw; the same joint of the other chela is elongated. The two posterior feet are nearly didactylous. The external foliation of the lateral fins of the end of the tail is larger than the internal. The carapace is slightly elongated, smooth, and terminated suddenly by a small beak. The abdomen is of considerable size, and nearly membranous. The other general characters are those of *Thalassina*. [THALASSINA.] The only species known is *Callianassa subterranea*, which is found on the sands of the sea-shore washed by the tides on the French and English coasts.



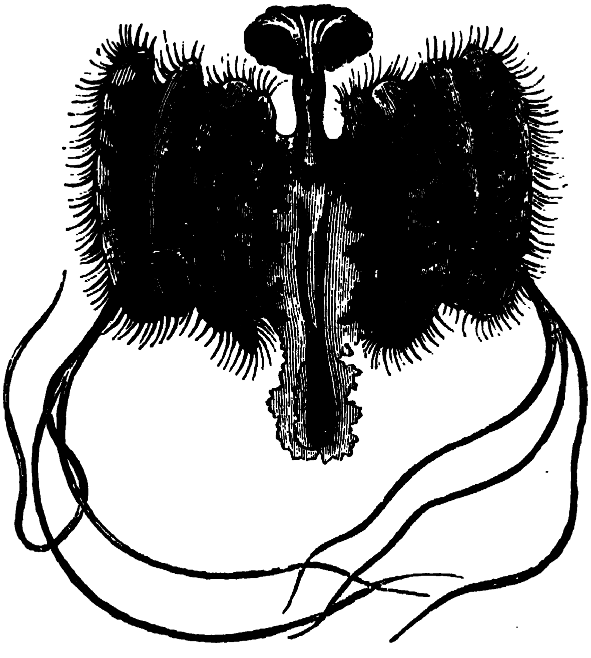
Callianassa subterranea.
a, Intermediate antenna; *b*, external antenna; *c*, right chela.

CALLIANIRA, or CALLIANYRA, a genus of Ciliograde *Acalaphæ*, established on no very sure foundations by Péron and Lesueur, in their 'Memoir on the *Pteropoda*,' and considered by them to belong to the type of the *Malacozoairia*. It seems however from its structure that in its general character it is not far removed from *Beröe*. Lamarck, who perceived this relation, states that it was first established by Péron, in manuscript, under the name of *Sophia*; and the species described by him had, according to his account, a membranous gelatinous wing, divided into two large folioles provided with cilia on their margins.

De Blainville, who observes that *Callianira* is only known by figures and descriptions not very complete in their details, states that Slabber's figure copied by Bruguières was drawn after an animal from the coasts of Holland, and that the description was taken from another belonging to the waters of Madagascar; information which De Blainville acknowledges that he owes to Professor Vanderhoeven. De Blainville adds that M. Eschscholtz refers them to two different species.

The following is the generic character given by De Blainville.—Body regular, gelatinous, hyaline, cylindrical, elongated, tubular, obtuse at the two extremities, and provided with two pair of wing-shaped appendages, which develop themselves in large foliations, and are fringed with a double row of vibratory cilia upon their edges. A pair of tentaculiform appendages, branched, and not ciliferous. A large transverse opening at one of the extremities, and probably another smaller one at the other.

Example, *Callianira triploptera*.



Callianira triploptera.

CALLI'CERA, a genus of Insects of the order *Diptera* and family *Syrphidæ*, section *Athericera*. This genus is allied to *Ceria* of Fabricius, and differs principally in having the body shorter and wider in proportion and silky. The second joint of the antennæ is shorter than the last, and forms with it an elongated, compressed, slightly-curved club.

CALLICHRO'MA, a genus of Coleopterous Insects of the section *Longicornes* and family *Cerambycidæ*, distinguished from the allied genera (*Cerambyx*, *Phœnicocerus*, &c.) by having the maxillary palpi smaller than the labial, and shorter than the terminal lobe of the maxillæ. The posterior tibiæ are generally much compressed.

As in the genus *Cerambyx*, the species of this genus emit a very agreeable odour.

CALLI'CHTHYS (Linnæus), a genus of Fishes belonging to the section Abdominal *Malacopterygii* and family *Siluridæ*. They are distinguished by the species having the body almost entirely protected by four ranges of large hard scaly plates: the head is also protected with plates of the same texture; the snout and under surface of the body are the only naked parts. The mouth is not deeply cleft, and is furnished with four long cirri, two from each corner; the teeth are very small; eyes small, and situated on the side of the head.

The species of this genus generally frequent rivers and streams. Like eels they can live for a considerable time out of water, and as they are natives of hot climates the streams which they inhabit not unfrequently dry up: when such is the case they are said to perform long journeys over land, directing their course to some other stream. In some instances they bury themselves in the mud. Their structure appears to fit them for these habits.

The genus *Callichthys* appears to be included in the genus *Cataphractus* of Willughby and Ray and some others among the older authors.

CALLI'DIUM, a genus of Coleopterous Insects belonging to the section *Longicornes* and family *Cerambycidæ*. It has the following characters:—Body depressed, thorax wider than the head, rounded at the sides; antennæ generally shorter than the body; palpi rather short, the terminal joint thicker than the rest, and truncated at the apex. Legs short; femora suddenly thickened towards the apex, especially in the males; tibiæ simple.

Callidium Bajulus is not an uncommon insect in this country. It lives during the larva state in fir-timber, and when it occurs plentifully is exceedingly destructive. The perfect insect is about three-quarters of an inch long, of a flattened elongate form, and dull black or pitch colour; the thorax is pubescent and has two smooth glossy tubercles on the disc; the elytra are furnished with a fascia (more or less distinct) of silvery-white hairs.

Instances have been recorded of these insects attacking the fir-rafters of houses, to which they are of course exceedingly injurious, and we have known instances when the perfect insects, in order to effect their escape, have perforated the lead with which the house-top was covered.

In many of the deal palings in the neighbourhood of London, and elsewhere, numerous oval-shaped holes (about a quarter of an inch in diameter) may be observed; these are formed by the perfect insect of this species of *Callidium* to effect their escape, having passed through the larva and pupa states within the wood.

Mr. Stephens in his 'Catalogue of British Insects,' enumerates thirteen species of this genus, but of these many have undoubtedly been imported in foreign timber.

CALLIGONUM, a genus of plants belonging to the natural order *Polygonaceæ*, of which one species, *C. Pallasia*, yields in its roots an amylaceous gummy matter, on which the Calmucks feed in times of scarcity. The fruits and branches are acid, and are chewed by the same people to allay their thirst. This plant is destitute of leaves, and grows in great abundance on the sandy steppes of Siberia. (Lindley, *Vegetable Kingdom*).

CALLIMO'RPHA (Latreille), a genus of Insects belonging to the order *Lepidoptera*, section *Nocturna*, and family *Lithosidæ* (Stephens). It has the following characters:—Antennæ slightly ciliated in the males; palpi small, three-jointed; legs moderate, the hinder tibiæ each with two pairs of spurs; body slender, especially in the males; wings large, somewhat triangular, with the hinder margins rounded.

Callimorpha Jacobææ, the Pink Underwing, is a very beautiful and common moth. When the wings are expanded it measures about an inch and a half in width. The upper wings are of a greenish-black colour, with two round pink spots at the apex, and an oblong dash of the same colour, extending nearly the whole length of and parallel to the outer margin. The under wings are entirely pink, with the exception of the margins, which are of the same tint as the ground-colour of the upper wings. The head, thorax, abdomen, and legs are entirely black.

The caterpillar of this moth is not uncommon in the neighbourhood of London. In some situations it is found in the greatest abundance in the month of June, feeding upon the flowers of the Ragwort (*Senecio Jacobæa*) and often upon Groundsel (*Senecio vulgaris*). It is of a bright yellow colour, with numerous slender black bands, and is sparingly covered with hair. The moth appears in the month of May.

CA'LLIODON, a genus of Fishes of the section *Acanthopterygii* and family *Labridæ*. This genus was separated from that of *Scarus* (Linn.) by Cuvier, and differs in the species having the lateral teeth of the upper jaw divided and pointed; the upper jaw is also furnished with an inner range of small teeth. *Scarus spinidens* of Quoy and Gaimard is given as an example of this genus. [SCARUS.]

CALLIO'NYMUS, a genus of Fishes belonging to the Abdominal *Acanthopterygii* and family *Gobiadæ*.

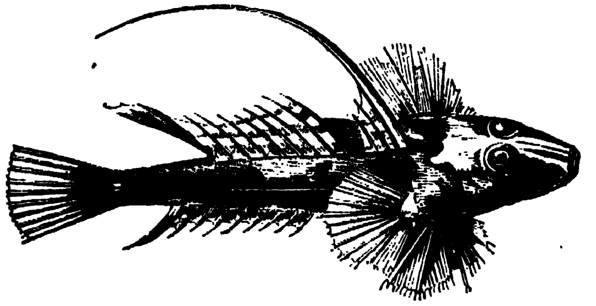
The species of this genus are known in England by the name of Dragonets. Their branchiæ have but a single small opening placed near the nape of the neck; their ventral fins are widely separated, larger than the pectorals, and situated under the throat; the head is oblong and depressed; the eyes are placed on the top of the head and rather close together; body smooth and without scales; intermaxillaries very protractile; teeth small, numerous, and placed on the jaws only; the anterior dorsal fin has the first ray elongated.

Two species of this curious genus (remarkable for the peculiarities in the branchiæ and ventral fins above noticed) are found on our own coasts. *C. Dracunculus*, the Sordid Dragonet, the Fox of the Kentish coast and the Skulpin of Cornwall, is the better known, being frequently met with at the mouth of the Thames. It is about 10 inches long and of a reddish-brown colour above; the under parts, the head, pectoral and ventral fins uniformly white; the dorsal fins are of an immaculate pale-brown.

C. lyra, the Gemmeous Dragonet, Yellow Skulpin of Cornwall and Gowdie of Scotland, very closely resembles the one above described, and indeed has by some been considered as the same species. There appears however to be very good grounds for separating them, independent of the difference of colour. The prevailing hue of this species is yellow of various shades, with sapphirine stripes and spots on the head and sides of the body. The ventrals and caudal fins are bluish-black.

In the Sordid Dragonet the head bears the proportion of one to five of the whole length of the fish, and is of the form of an equilateral triangle: the distance between the eyes and the nostrils is only equal to one diameter of the former.

In the Gemmeous Dragonet the head is of an oblong-ovate form, and its length compared with that of the fish is as one to four: this species may also be distinguished from the former by its less depressed form.



Gemmeous Dragonet (*Callionymus lyra*).

The latter species has been found on various parts of our own coast as well as that of Ireland. It also occurs in the Mediterranean and on the coast of Norway.

The Dragonets live at the bottom of the water, as might be supposed from the disposition of the eyes. Their food consists of small shell-fish and worms. They are sometimes caught by the shrimpers whilst fishing.

CALLI'STUS (Bonelli), a genus of Coleopterous Insects belonging to the family *Harpalidæ* (M'Leay). The following are its characters:—Three basal joints of the anterior tarsi dilated in the males. Palpi with the terminal joint elongated, rather ovate, and terminated almost in a point. Antennæ filiform and slightly compressed. Labrum transverse, emarginated anteriorly. Head somewhat triangular. Thorax nearly heart-shaped. Body rather short and depressed.

Only one species of this genus has hitherto been discovered, but it is found almost all over Europe: it is not uncommon in France, and is found beneath stones. In England it is rather scarce.

This species, *Callistus lunatus*, is conspicuous in the cabinets of British insects for its beauty. It is about a quarter of an inch long; the head and under parts of the abdomen are of a greenish-black colour, the thorax is reddish-yellow, and the wing-cases are yellow with six black spots, placed, two at the base, one on the disc of each elytron which extends to the outer margin, and two at the apex; these spots are large, and occupy about one-half of the whole surface of the elytra. The antennæ are black, with the two basal joints yellow. The legs are black, with the base of the femora and tibiæ yellow. The head and thorax are very thickly punctured; the elytra are punctate-striated. The upper parts, with the exception of the head, are devoid of glossiness.

CALLITHAMNION. [ALGÆ.]

CALLITRICHA'CEÆ, *Starworts*, the Callitriche Tribe, a small natural order of Achlamydeous Dicotyledonous Plants, consisting of a few obscure floating species, all of which belong to the genus *Callitriche*. The distinctive character resides in the presence of several one-seeded carpels combined into a single pistil with two styles, and altogether destitute of any floral covering. Brown and many others consider the order related to *Halorageæ*. Lindley, who formerly placed it near *Podostemaceæ*, now agrees with Endlicher that its proper position is near *Euphorbiaceæ*, of which it may be regarded as an aquatic form. In the genus *Callitriche* the flowers are without calyx or corolla, with 2 bracts at their base; 1 stamen; 2 ovaries, each 2-lobed and imperfectly 2-celled; the styles 2, subulate; the fruit dry, separating into 4 indehiscent carpels. Kützing has figured a deciduous calyx belonging to this genus. Five species have been described. Four of these are natives of Great Britain. They are water-plants with smooth leaves, and are known by the name of Water-Starworts. *C. verna* is common in stagnant waters and slow streams. *C. platycarpa* is found on mud or in shallow water; seldom, and then apparently by accident, in deep water. *C. pedunculata* is found in marshes; and Babington has described a variety, *C. p. sessilis*, which is found in lakes. *C. autumnalis* is found in streams, but is rare. The surface of *C. verna*, and probably of the other species, is covered with rosette-formed epidermal appendages. The same bodies are found on *Hippuris*. (Lankester, *British Association Transactions*; Babington, *Manual of Botany*.)

CALLI'TRICHE. [CALLITRICHACEÆ.]

CALLITRIS, a genus of plants belonging to the natural order *Coniferæ*. Dr. Lindley states, on the authority of Brongniart and Schousboe, that Sandarach is yielded by a species of this genus, the

C. quadrivalvis, and not from *Juniperus communis*, as is frequently supposed. He also adds that he has seen "a plank two feet wide of this Sandarach-Tree, which is called the Arar-Tree in Barbary. The wood is considered by the Turks indestructible, and they use it for the ceilings and floors of their mosques." (Lindley, *Vegetable Kingdom*.)

CALLU'NA (from *καλλύνω*, to make beautiful), a genus of plants belonging to the natural order *Ericaceæ*. It has a 4-parted membranous coloured calyx, longer than the 4-cleft campanulate corolla, surrounded by four green bracts; 8 stamens, with dilated filaments; the capsule 4-celled, the dissepiments adhering to the axis; the valves opening at the dissepiments, and separate from them. There is only one species of this genus, the Common Heath (*C. vulgaris*). It is a low tufted shrub with small sessile closely-imbricated keeled leaves, arranged in four rows, each leaf having two small spurs at the base, and nearly or quite smooth. The colour of the flowers varies from a deep red to a white, and numerous varieties have been named. This plant is common on every heath in Great Britain. The varieties are ornamental when planted in the garden. They should be grown in a peat soil, and may be propagated by layers or cuttings under a bell-glass. (Babington, *Manual of British Botany*.)

CALOCHO'RTUS, a beautiful genus of Bulbous Plants belonging to the natural order *Liliaceæ*, and nearly allied botanically to the fritillary and tulip, from both of which it is immediately known by the sepals being of a different form, colour, and texture from the petals. Several species have been introduced into England from California, where or near which country they are exclusively found wild. Their exact localities, and the precise conditions of climate under which they occur, are however nearly unknown. It would appear that they inhabit a mild climate, subject to rains, and a moderately high temperature during their season of growth, but dry and cool subsequently. Accordingly it is found that in this country they do not succeed very well unless they are cultivated in pits where they are protected from frost and from water stagnating about their roots, and can be exposed freely to light and air when growing. They are so exceedingly impatient of wet near their bulbs when not in a growing state, that prudent gardeners take the precaution to dig them up and keep them dry from the time when the leaves are withered to the recommencement of their vegetation. When they are replanted they will scarcely bear any water until the young leaves begin to appear above the soil.

CALOPHYLLUM (from *καλός*, beautiful, and *φύλλον*, leaf), a genus of plants belonging to the natural order *Guttiferæ*. It has a bractless calyx, consisting of from 2-4 unequal coloured sepals; 4 petals (sometimes 2) opposite the sepals; indefinite stamens, free or connected at the base; filaments short; anthers inserted by their base, 2-celled, bursting longitudinally; the style twisted, crowned by a large capitate stigma, which is usually lobed; fruit drupaceous, globose or egg-shaped, 1-celled, 1-seeded; the seeds large. The species are trees, the leaves of which have numerous transverse parallel veins, which give them a very beautiful appearance.

C. Inophyllum has oblong or obovate obtuse leaves, usually emarginate; round branches; loosely racemose flowers; racemes axillary, 1-flowered; usually opposite peduncles. This tree is a native of the East Indies, and often attains a height of 90 or 100 feet. It has large handsome leaves like those of a water-lily, snow-white fragrant flowers, and a fruit about the size of a walnut. When the trunk is wounded it exudes a yellow viscid juice, which frequently hardens to the consistence of a gum. It is a common plant in Malabar, where it yields fruit twice a year—in March and September—and frequently attains the age of 300 years. The nuts afford a fixed oil, which is expressed, and used for burning in lamps, for making ointment, &c. This tree is cultivated in Java for the sake of its shade and the fragrance of its flowers. The bark and the exudation are used for medicinal purposes.

C. Calaba, Calaba-Tree, has obovate or oblong, obtuse or emarginate leaves; hermaphrodite or male flowers; lateral very short racemes. This plant is a tree 60 feet in height, and is a native of the Caribbee Islands. It has white sweet-scented flowers, and a green fruit something like the cornelian cherry, which contains a white solid kernel. An oil is expressed from the seed for domestic uses and for burning in lamps. The timber is used for various purposes, especially for staves and cask-headings. Lindley says that "the true East Indian Tacamahaca is produced by *Calophyllum Calaba*." There are however several gums brought into the market under the name of Tacamahaca, of which formerly more was used than at the present day. The 'Tacamahaca seu Resina Tacamahaca' of the old Pharmacopœias appears to have been the produce of the *Elaphrium tomentosum* and *E. excelsum*, plants belonging to the natural order *Amyrideæ*. It is described as a resin of a brownish yellow colour, spotted with white, easily broken into pieces, which have a shining fracture, easily melting in the fire, and having a pleasant scent. Cullen says that it was not employed in his day "as an internal medicine; and as an external I cannot perceive its virtues." It was used for making plasters as a counter-irritant, for which there are forms in the continental Pharmacopœias at the present day. There is however another form of Tacamahaca brought to Europe called 'Tacamahaca-in-Shells.' It has got this name from being collected in little gourd-shells. This is the true East Indian Tacamahaca, which is collected from *C. Inophyllum* in the East Indian Islands and from *C. Tacamahaca* in Madagascar and the Mauritius. *C. Brasiliense* yields an acrid aromatic lemon-scented resin. *C. angustifolium* is the Piney-Tree of Penang, and yields a hard timber.

(Bischoff, *Medicinisch-Pharmaceutische Botanik*; Loudon, *Encyclopædia*; Don, *Gard. Dict.*; Lindley, *Vegetable Kingdom*.)

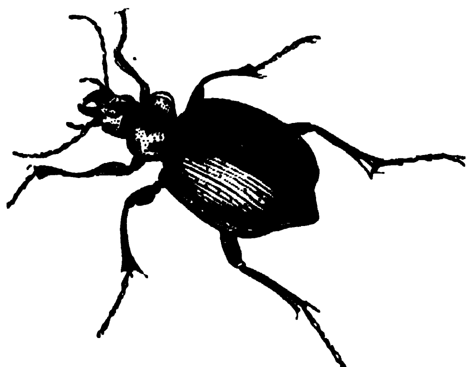
CA'LOPUS, a genus of Coleopterous Insects belonging to the section *Stenelytra* and family *Œdemeridæ*. The species are distinguished by having the femora of the posterior legs of the same size in both sexes, or nearly so; the antennæ with the second joint much shorter than the third, more or less serrated, and inserted into an emargination of the eyes. [ŒDEMERA.]

CALOSO'MA, a genus of Coleopterous Insects belonging to the section *Geodephaga* (M'Leay), and family *Carabidæ*. It is known by the following characters:—Three basal joints of the anterior tarsi, in the males, much dilated, the fourth joint slightly so; antennæ with the third joint longer than the rest; labrum bilobed; mandibles simple, slightly bent, and transversely striated; thorax short; elytra generally rather broad and short.

This genus is very closely allied to the true *Carabi*; indeed so much so, that it is difficult to point out any very tangible distinguishing characters; and yet the entomologist is seldom puzzled in separating them, even without close examination.

There is a considerable difference in the general appearance of the species of the two genera, and we think this in a great measure arises from the comparative proportions of the head and thorax. In *Calosoma* these parts are always smaller and considerably shorter in proportion to the body (which is generally broad) than in *Carabus*. The eyes are generally more projecting; and M. Dejean mentions the larger-sized jaws, and their being always transversely striated, as a good distinction.

To the genus *Calosoma* belongs our largest and most beautiful British Carabideous insect, the *C. Sycophanta*. It is about an inch long; the head, thorax, and under parts of the body are of a beautiful blue colour, and the elytra are green, with red reflections more or less conspicuous in different examples; the legs and antennæ are black.



Calosoma Sycophanta.

Most of the best British collections contain this insect, and some even several specimens: it must nevertheless be considered a rare insect in this island, hardly ever more than one specimen having been found at one time. In France and Germany it is not uncommon, and is found in woody districts. Most of the British specimens have been taken on the sea coast.

C. Inquisitor is the only other species of this genus found in this country. It is about three-quarters of an inch in length, and of a bronze or brassy-green above, and black beneath. This species, though by no means common, is far more abundant than the last. It has been frequently met with crawling up the trunks of oak-trees in the spring of the year, about the time that that tree begins to put forth its leaves. Most probably it feeds upon the young caterpillars, which are then abundant.

Unlike most genera of insects, this appears to be confined to no particular quarter of the globe, species having been met with in almost all countries. About thirty species are known; their prevailing colours are various shades of green, generally of a brassy hue, and sometimes black.

CALOTHRIX. [ALGÆ.]

CALOTRAGUS. [ANTILOPEÆ.]

CALOTROPIS, a genus of plants belonging to the natural order *Asclepiadaceæ*. One species, *C. gigantea* (*Asclepias gigantea*, Linnæus), is the Mudar-Plant, Akund or Yercum of the Hindoos. It yields a milky juice, which is extensively used in India as a medicinal agent, as are also the root and bark. [MUDAR, in ARTS AND SC. DIV.]

CALPE. [ACALEPHÆ.]

CALTHA, a genus of plants belonging to the natural order *Ranunculaceæ*. Two species are met with in this country; one, *C. palustris*, the Water-Caltrops or Marsh-Marigold, commonly in meadows and by the side of wet ditches. It is very much like a *Ranunculus*, from which genus *Caltha* chiefly differs in having a calyx and corolla mixed together, no scale at the base of the petals, and many seeds in each carpel. The other species is *C. radicans*, which is very local. The species partake of the acridity of *Ranunculus* itself.

CALUMBO-ROOT, the bitter tonic root of an African plant called *Cocculus palmatus*. [COCCULUS.]

CALYCANTHA'CEÆ, *Calycanths*, the Calycanthus Tribe, a natural order of hardy Dicotyledonous Plants, well known in gardens for the delicious fragrance of their blossoms. They are in some respects allied to the *Magnolia*, or Star-Anise Plant (*Illicium*), in consequence of their chocolate-coloured flowers with the segments overlying each other in several rows, and because also of their peculiar fragrance; their true affinity is however with *Rosaceæ*, as the mass of their characters sufficiently proves; especially the unusual circumstance of the cotyledons of the embryo being rolled up both in this order and in the genus *Chamæmeles* in *Rosaceæ*.

Calycanthaceæ consist of but two genera, *Calycanthus* and *Chimonanthus*, which agree in having—1st, an imbricated calyx and corolla that pass insensibly into each other, and combine at their bases into a thick fleshy tube; 2nd, a small number of perigynous stamens, whose anthers are adnate and are tipped by a projection of the connective; 3rd, several one-seeded nuts inclosed in the tube of the calyx; and 4th, a convolute embryo, destitute of albumen. Their wood is remarkable for the glandular nature of the woody tubes; and for having, in addition to the usual structure of exogens, four imperfect axes with concentric circles, lying at equal distances in the bark near the circumference, on which they produce externally four elevated lines or wheals.

The two genera are thus distinguished:—*Calycanthus*, or the Carolina Allspice, has 48 stamens arranged in four rows, the innermost being rudimentary; and a great many nuts inclosed in a calyx, which is naked at its apex. It consists of small shrubs, natives of North America, with fragrant chocolate-coloured flowers, appearing along with the leaves in May or June.

Chimonanthus, or the Japan Allspice, has 10 stamens, all perfect and inserted in a double row; only one or two nuts to each calyx-tube, which is crowned and closed up by the permanent recurved stamens. The only species is found wild in Japan, and has fragrant lemon-coloured blossoms, appearing in the winter after the fall of the leaves. Botanists call it *Chimonanthus fragrans*, and distinguish three varieties:—1st, the pale kind, which has long been in gardens, and has flowers the colour of which is very slightly yellow; 2nd, the large-flowered, with bright yellow flowers twice as large as those of the last; and 3rd, the small-flowered, which is in all respects the same as the first, except that its blossoms are less than half the size. These plants are multiplied with some difficulty by layering.

(Lindley's *Vegetable Kingdom*.)

CALYCANTHUS. [CALYCANTHACEÆ.]

CALYCERA'CEÆ, *Calycers*, a small natural order of Monopetalous Dicotyledons, differing from *Compositæ* in nothing but their seeds having albumen, and being pendulous, and in their anthers being only half syngenesious. It has five genera and ten species. They are natives of South America, but more especially of South Chile.

CALYCIFLO'RÆ, an artificial division of Polypetalous Dicotyledonous Plants, proposed by Jussieu and adopted by De Candolle. It is characterised by the stamens adhering more or less to the side of the calyx; or, in the language of the French school of botanists, being perigynous.

CALYCOPHYLLUM (from κάλυξ, calyx, and φύλλον, leaf), a genus of plants belonging to the natural order *Cinchonaceæ*. It has the limb of the calyx truncate or bluntly 5-toothed, one of the teeth expanded into a petiolate coloured membranous leaf; the corolla campanulate or funnel-shaped with a 5-plaited limb; 5 stamens, the filaments rising from the throat free, the length of the corolla; the anthers oval, exserted; the style ending in 2 reflexed stigmas; the capsule dehiscing at the apex, oblong, 2-celled, many-seeded; the seeds fixed to the linear placenta, imbricate, oblong, girded by a very narrow membranous wing. The species are small smooth trees, with opposite glabrous leaves, short stipules, and flowers disposed in axillary and terminal dichotomous corymbs.

One of the most remarkable species of this genus has been described by Sir Robert Schomburgk as a native of British Guyana. There are several genera closely allied to *Calycophyllum*, as *Mussænda Pinkneya*, &c., in which one of the teeth of the calyx expands into a petioled and coloured leaf of a membranaceous texture. In the species discovered in Guyana the bract-like expansion of the calyx has a rose colour, and as the flowers are very numerous the whole tree assumes the colour of the rose. In describing the discovery of this plant, Sir Robert says, "Let imagination convey you to the great garden of nature in Guyana, clothed in tropical exuberance; and, among those productions of a congenial sun and fertile soil, figure to yourself trees from 40 to 50 feet high, presenting a mass of leaves the colour of our favourite flower, from a deep pink to the lightest rose, and perhaps your fancy will assist you to form some idea of the picture I beheld at one of the valleys of the river Rapunnuni, where a high mountain on the river's left bank turns its bed boldly to the east. The banks of the stream and the steep side of the hill were alike covered with trees clothed with rose-coloured leaves; and only on a near approach could the shining green leaves and the spikes of flowers of a velvety blue be discovered."

This plant is called by its discoverer, in honour of the present Lord Derby, *Calycophyllum Stanleyanum*. The wood of the tree is very hard. It is very bitter to the taste, and like the rest of the order is probably febrifugal.

(Hooker, *London Journal of Botany*, 1844.)

CALY'MENE, the generic title, in Brongniart's classification of *Trilobites*, for the species of *Crustacea* allied to the well-known Dudley fossil, *Calymene Blumenbachii*. [TRILOBITES.]

CALYMMA, a genus of Ciliograde *Acalephæ*, thus characterised by Eschscholtz:—Body but little elevated, compressed, widened, as it were, and provided on each side with a considerable appendage, taking its rise from four other smaller appendages, free at their extremity, near the mouth, and furnished with the series of cilia. The species on which this genus was established was taken in the South Seas near the equator.

CALY'PTRA, in Botany, a name given to a hood-like body connected in some plants with the organs of fructification. In the genus *Pileanthus* it covers over the flower, and is formed of united bracts; in *Eucalyptus* and *Eudesmia* it is simply a lid or operculum to the stamens, and is produced in the former by the consolidated sepals, in the latter by the petals in the same state: in mosses it is seated upon the end of the fruit-stalk, inclosing the spore-vessel, and is a leaf rolled round the latter and torn away from its base. In *Jungermannia* it exists in the form of a cup or wrapper at the base of the fruit-stalk, which, instead of carrying it up upon its point, pierces through its apex and leaves it behind.

CALYPTRÆ'IDÆ, a family of Gasteropodous *Mollusca*, formerly arranged under the genus *Patella* of Linnæus, and known by collectors as Chambered Limpets, comprising the genera *Calyptræa* and *Crepidula* of Lamarck, with the sub-genera into which they have been divided by Lesson.

"When," says M. Deshayes, in his edition of Lamarck, "collections contained but a small number of *Calyptrææ* and *Crepidulæ*, and when the animals of these two genera were unknown, it was natural and proper to preserve them both; but now the resemblance of the animals of these two genera is proved, not only by what M. Cuvier formerly stated in the 'Annales du Muséum,' but also by the more recent works of M. Lesson, of Messrs. Quoy and Gaimard, and of Mr. Owen. Already we had perceived, in publishing our work upon the environs of Paris, as well as in our articles '*Calyptræa*' and '*Crepidula*' in the 'Encyclopédie,' that there existed a great resemblance between the shells of these two genera. One sees in effect, in certain *Crepidulæ*, the summit taking a spiral shape upon the side of the shell, and raising itself insensibly in a succession of species so as to show an incontestable passage between the *Crepidulæ* and spiral *Calyptrææ*, which we would particularly designate by the name of Trochiform *Calyptræa*. As in the *Calyptrææ*, properly so called, there exist a certain number of particular forms which may serve to group them in sections, it was necessary to see whether the species having in their interior a lamina or plate of a funnel shape afforded proof of a passage to the *Crepidula*, like those which are trochiform. This passage does exist; so that from the entire facts we may come to the conclusion that the two genera, *Calyptræa* and *Crepidula*, ought to be united for the future in the system. This conclusion, which we had in some sort foreseen, has been rigorously drawn and proved by incontestable evidence in the work lately published by Mr. Broderip, in the first volume of the 'Transactions of the Zoological Society of London.' M. Lesson, in the conchological part of the great work published on the return of the expedition in the corvette La Coquille, had attempted to establish in the united genera *Calyptræa* and *Crepidula* many sub-genera, of which some have been adopted by Mr. Broderip as sections of the entire genus *Calyptræa*. These sections, of which some persons think that they can make genera, are connected one with another by the strongest affinities, and cannot be separated into genera on account of the resemblance of the animals."

Deshayes then proposes the following sections of the [illegible] genus *Calyptræa*:

1. Those which have in their interior, and fixed to the summit, a shelly plate, hollowed out into a sort of gutter, which may be compared to a hollow cone of paper cut longitudinally in two, and of which one portion has been removed. (*Calyptræa equestris*.)

2. Those which have a delicate plate or lamella in the form of a funnel, fixed either to the side or the summit: a well-defined section, representing nevertheless a passage towards some of the *Crepidulæ*.

3. Uniting all the species from those which begin to have a very short lamella attached to the internal side (*Calyptræa extinctorium*) to those whose lamella forms spiral turns (*Calyptræa trochiformis*), the gradations being very insensible. To this section M. Deshayes thinks that many of Lamarck's *Crepidulæ* should be referred.

4. *Crepidula*, properly so called. This section he says might be subdivided, taking for a basis of the subdivision characters of less value than those relied on for forming the four principal sections.

Some idea of the variety of shape to which these shells are subject may be obtained from the following passage in Mr. Broderip's paper:—"I have before me specimens taken from under the same stone, evidently of the same species, varying in shape from a regular high cone to an almost flat surface, with nearly every intervening irregularity of circumference that can be imagined."

The species of *Calyptræidæ* are numerous and widely diffused; but the great development of the form is to be found in warm climates, where many of the species attain considerable size, and are remarkable for their form and the richness of their colour. They are found sticking on rocks, on and under stones, on other living and dead shells and submarine substances at depths varying from the surface to 40 fathoms, on sea-coasts, in æstuaries, and in tidal rivers.

Two genera of this family have representatives in the British seas—*Pileopsis* and *Calyptræa*. Each genus has one species. *Pileopsis Hungaricus* is a common Limpet on our shores, and is known by the name of the Bonnet or Large Foolscap Limpet. *Calyptra Sinensis* is essentially a southern British shell. It does not range north of Britain, but extends southward to the Mediterranean. Both these species are found fossil, and date back as far as the Coralline Crag.

CALYSTE'GIA (from καλὺξ, calyx, and στέγω, to cover), a genus of plants composed of species formerly included under *Convolvulus*, and separated by Robert Brown. It is distinguished by two large bracts which inclose the flower. It has a 5-parted calyx, a campanulate 5-plicate corolla, one style, a 2-lobed stigma, globose or terete lobes, a 2-celled ovarium with 2 ovules; the capsule only 1-celled from the shortness of the dissepiment. The species are lactescent, glabrous, twining or prostrate herbs, with solitary 1-flowered peduncles.

C. Sepium, Great Bindweed, has sagittate or cordate very acute leaves; lobes truncate, entire, cordate, keeled; acute bracts, longer than the calyx, but one-half shorter than the corolla; the peduncles square; sepals acute. This is the *Convolvulus Sepium* of older botanists. The genus *Calystegia* is not adopted by Koch, Babington, and other botanists. It is a native of Europe, in hedges, and is found in Great Britain very common. It possesses apparently the properties of the genus *Convolvulus*. Haller and Withering state that the expressed juice of the root may be used as a substitute for scammony. It is sometimes called German Scammony. In doses of 20 or 30 grains it has been recommended as a hydragogue cathartic in dropsies, by Mason Good.

C. Soldanella, Sea Bindweed, has trailing glabrous rather fleshy leaves, reniform, entire, or a little angular; peduncles angular, angles winged; bracts large, ovate, blunt, mucronate, generally shorter than the calyx. It is a native of many parts of Europe on the sea-coast, and also some parts of Asia. It is common on the coasts of Great Britain. The young stalks are sometimes eaten pickled. The juice of the mature plant is however a cathartic.

Several other species of this genus are described. Like the *Convolvuli* they are elegant plants in blossom, and are of the most easy culture. They may be propagated by pieces of the root or by seeds. The *C. Soldanella* should now and then be watered with salt-water.

(Don, *Gardener's Dictionary*.)

CALYX, the external wrapper of a flower within the bracts. Usually it is green and leaf-like, sometimes however it is coloured like a corolla, from which it is only known by its being the outermost of the rows of floral envelopes. It consists of leaves called sepals, which are sometimes separate, when the calyx is polysepalous, and sometimes united into a sort of cup by the edges, or monosepalous. Occasionally it is converted into feathery or short divisions, when it is named pappus; or it is altogether reduced to a small rim, so as to be hardly visible. In some plants it grows to the sides of the ovary, and is technically called superior, while it is named inferior if it is quite separate from that part. Its segments are usually of the same number as those of the corolla, and alternate with them. The office of the calyx appears to be, in its ordinary green state, merely that of protecting the tender parts that are formed within it; but when it is coloured and similar to a corolla, we can scarcely doubt that in such cases it also performs the part of a corolla. [COROLLA.] In some instances, as in that of pappus, it seems merely intended as a means of transporting seeds to a distance by enabling them to catch the wind by the wings which it at that time resembles. This is especially seen in many of the fruits of *Compositæ*. The foliar nature of the sepals is well seen in the cases of *Calycophyllum*, *Mussænda*, &c., where the sepals naturally grow into leaves.

CAMASSIA, a genus of Bulbous Plants belonging to the natural order *Liliaceæ*. The bulbs of one of the species (*C. esculenta*) are eaten by the North American Indians under the name of Quamash.

CAMBING OUTAN. [ANTILOPEÆ.]

CAM'BIUM, a viscid substance that appears in the spring between the wood and bark of exogenous trees. It is in this substance that the young cells are formed which become the wood of the following year. This substance disappears every spring after the complete formation of the wood, which then adheres firmly to the bark; but it re-appears whenever the plant is again called into growth, as at midsummer in those species which shoot twice a year, like roses, peaches, &c.

CAMBOGE. The produce of several species of plants belonging to the natural order *Guttiferæ* is known by this name. It is a gum-resin, and has purgative properties. On account of its bright yellow colour it is also used as a pigment. [STALAGMITES; GARCINIA; GUTTIFERÆ.]

CAMBRIAN ROCKS. Science is indebted to Professor Sedgwick for having established in North Wales, beyond a doubt, the important fact, that beneath the slates and flags of Denbighshire, which belong to the Upper Silurian Strata, occur in the Berwyn Mountains and in the vicinity of Bala other strata containing Lower Silurian fossils, to the extent of several thousand feet in thickness. In South Wales the progress of the Geological Survey, under Sir H. De la Beche, has established the fact of very considerable thicknesses of partially fossiliferous rocks beneath the Llandeilo (or Lowest Silurian) Strata of Murchison. By these labours we perceive that the Palæozoic forms of organisation descend, in Wales, many thousand feet below the lowest recognised Silurian strata, and the subjoined view of the nomenclatures, separately proposed by Sedgwick and Murchison, will give an idea of the relations of these rocks.

Lower Palæozoic Strata.		Upper Silurian. (Murch.)	Ludlow Rocks. Wenlock Rocks.
	Cambrian Strata. (Sedgw.)	Lower Silurian. (Murch.)	Caradoc Rocks. Llandeilo Rocks.
		Groups yet to be named.	—————— ——————

Hypozoic Strata of Cumberland and Scotland.

Thus it appears that the Cambrian Strata are not exactly equivalents of the Lower Silurians, but include a great range of other strata below those originally defined by Sir Roderic Murchison. Viewed, however, without reference to nomenclature, the Cambrian and Lower Silurian Rocks form one type, and may perhaps deserve to be ranked as one great Protozoic System.

CAMEL. [CAMELUS.]

CAMELI'NA, a genus of plants belonging to the natural order *Cruciferæ*, to the sub-order *Latiseptæ*, and the tribe *Camelineæ*. It has a subovate pouch, the valves ventricose, with a linear prolongation at the end, which is confluent with the persistent style.

C. sativa, Gold of Pleasure, has pear-shaped pouches, intermediate stem, leaves lanceolate, sagittate at the base, entire or denticulate. It has small yellow flowers. Its name is a burlesque on the humble appearance of the plant. Babington admits it into his British Flora, but it is undoubtedly a foreign plant, which has been introduced with the seed of flax. It is found abundantly in the corn and flax fields of the Continent, from whence the seed is brought to this country.

C. dentata is another species frequently found in Great Britain, in company with the last, and introduced in the same way.

CAME'LLIA, a genus of plants belonging to the natural order *Ternstromiaceæ*, and nearly related to the plants which yield the tea of the shops. All the species are natives of China and Japan, or of corresponding climates in the north of India, whence they have been introduced to Europe. *C. Japonica*, a species with broad shining leaves, and red flowers, is the origin of the numerous beautiful varieties now so common in our gardens. The principal part of these have been raised by the skill of the Chinese or Japanese, and are remarkable not only for their gay colours, but for the great symmetry with which their petals are arranged, the flowers when seen in perfection resembling nothing so much as beautiful shell-work. The sorts that have been raised in this country are in most instances inferior to the Chinese in symmetry, but they occasionally surpass them in richness of colour. They are multiplied by cuttings, grafts, and buds, and also by seeds, which the Waratah and some single sorts produce in plenty.

The other species of *Camellia* in our gardens which deserve notice are, the *C. maliflora*, the Apple-Blossomed Camellia, which is probably a mere variety of the last; *C. oleifera*, whose seeds yield a valuable oil in China; and *C. reticulata*, which is by far the handsomest of all. The leaves of this species are very remarkably netted, and the semi-double flowers, which are sometimes as much as six inches across, are of a deep rich rose-colour. For the culture of these plants see CAMELLIA, in ARTS AND SC. DIV.

CAMELOPARD. [GIRAFFA.]

CAMEL'S-THORN a name given to a species of *Alhagi*, the *A. Camelorum*. [ALHAGI.]

CAMELUS a genus of Ruminant Animals without horns; Gamal of the Hebrews, Djemal of the Arabs, Κάμηλος of the Greeks, Camelus of the Romans, Cammello of the Italians, Camello of the Spaniards, Kameel of the Germans, Chameau of the French, and Camel of the English. It includes two species, *C. Bactrianus*, the Camel, and *C. Arabicus*, the Dromedary.

The Camels have 34 teeth: 16 in the upper jaw; namely, two incisors—for the camels and the llamas have these, and form the exceptions, the other ruminants being without any incisors in the upper jaw—two canines, twelve molars: 18 in the lower jaw; namely, six incisors, two canines, ten molars. The incisors of the upper jaw bear a close resemblance to canine teeth, for they are conical, compressed at the sides, pointed, and somewhat curved or hooked. There is another difference between the Camels and the other Ruminants: the former have the scaphoïd and cuboïd bones of the tarsus separated. Instead of the great horny case or shoe, which envelopes all the lower part of each toe and determines the figure of the ordinary cloven hoof, the camels have only a small one, or rather the rudiment of one, adhering only to the last joint of the toe, and symmetrical in form, like the hoofs of the *Pachydermata*. These and other peculiarities of form lead to the opinion that the Camels and the Llamas form the link between the *Ruminantia* and *Pachydermata*.

The characters of the genus may be thus summed up:—Lower incisors in the form of cutting wedges; upper incisors sub-lateral; canines conical, sub-erect, strong; false molars situated in the inter-dentary space on either side; head long; upper lip cleft; nostrils slit obliquely; eyes prominent; ears small. Neck elongated. Back with fleshy bosses or hunches; tail moderate. Toes united below. Teats ventral, four in number. Hair inclining to woolly. Callosities on the breast, and flexible points of the extremities. The upper lip of the Camel swollen and divided, the projecting orbits of its eyes, the lengthened and certainly not graceful neck, the back bossed with a hump or humps, and croup comparatively weak, supported upon the long and awkward-looking legs terminating in apparently disproportioned feet, are not materials for producing elegance of form: and indeed the air of the animal is altogether grotesque; but this uncouth shape is, as we shall presently see, one of those admirable examples of contrivance which must strike the most casual observer.

The two species of Camel were well known to Aristotle, who, in his 'Natural History' (ii. 1), mentions both the Arabian and the Bactrian, remarking that the latter has two humps, whereas the former has but one.

The organisation of the Camels is wonderfully adapted to their habits and uses to man. The pads or sole-cushions of the spreading feet are divided into two toes without being externally separated, which buoy up as it were the whole bulk with their expansive elasticity from sinking in the sand, on which it advances with silent step—the nostrils so formed that the animal can close them at will to exclude the drift sand of the parching simoom—the powerful upper incisor teeth for assisting in the division of the tough prickly shrubs and dry stunted herbage of the desert—and, above all, the cellular structure of the stomach, which is capable of being converted into an assemblage of water tanks, bear ample testimony to the care manifested in the structure of this extraordinary quadruped.

The stomach of the Camel has been well described by Sir Everard Home.

"The camel's stomach," he says, "anteriorly forms one large bag, but when laid open this is found to be divided into two compartments, on its posterior part, by a strong ridge, which passes down from the right side of the orifice of the œsophagus, in a longitudinal direction. This ridge forms one side of a groove that leads to the orifice of the second cavity, and is continued on beyond that part, becoming one boundary to the cellular structure met with in that situation. From this ridge eight strong muscular bands go off at right angles, and afterwards form curved lines, till they are insensibly lost in the coats of the stomach. These are at equal distances from each other, and, being intersected in a regular way by transverse muscular septa, form the cells. This cellular structure is in the left compartment of the first cavity, and there is another of a more superficial kind on the right, placed in exactly the opposite direction, made up of twenty-one rows of smaller cells, but entirely unconnected with the great ridge. On the left side of the termination of the œsophagus a broad muscular band has its origin from the coats of the first cavity, and passes down in the form of a fold parallel to the great ridge, till it enters the orifice of the second, where it takes another direction. It is continued along the upper edge of that cavity, and terminates within the orifice of a small bag, which may be termed the third cavity. This band on one side and the great ridge on the other form a canal, which leads from the œsophagus down to the cellular structure in the lower part of the first cavity. The orifice of the second cavity, when this muscle is not in action, is nearly shut; it is at right angles to the side of the first. The second cavity forms a pendulous bag, in which there are twelve rows of cells, formed by as many strong muscular bands, passing in a transverse direction, and intersected by weaker muscular bands, so as to form the orifices of the cells. Above these cells, between them and the muscle which passes along the upper part of this cavity, is a smooth surface, extending from the orifice of this cavity to the termination in the third.

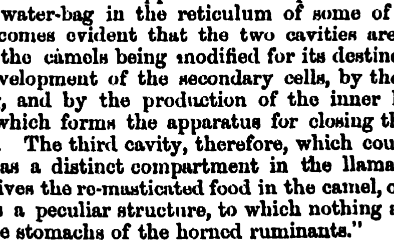
"From this account it is evident that the second cavity neither receives the solid food in the first instance, as in the bullock, nor does the food afterwards pass into the cavity or cellular structure. The food first passes into the first compartment of the first cavity, and that portion of it which lies in the recess, immediately below the entrance of the œsophagus, under which the cells are situated, is kept moist, and is readily returned into the mouth along the groove formed for that purpose, by the action of the strong muscle which surrounds this part of the stomach, so that the cellular portion of the first cavity in the camel performs the same office as the second in the ruminants with horns. While the camel is drinking, the action of the muscular band opens the orifice of the second cavity at the same time that it directs the water into it; and when the cells of that cavity are full, the rest runs off into the cellular structure of the first cavity immediately below, and afterwards into the general cavity. It would appear that camels, when accustomed to go journeys, in which they are kept for an unusual number of days without water, acquire the power of dilating the cells so as to make them contain a more than ordinary quantity as a supply for their journey; at least, such is the account given by those who have been in Egypt. When the cud has been chewed, it has to pass along the upper part of the second cavity before it can reach the third. How this is effected without its falling into the cellular portion, could not, from any inspection of dried specimens, be ascertained; but when the recent stomach is accurately examined the mode in which this is managed becomes very obvious. At the time that the cud has to pass from the mouth the muscular band contracts with so much force that it not only opens the orifice of the second cavity, but acting on the mouth of the third brings it forward into the second, by which means the muscular ridges that separate the rows of cells are brought close together, so as to exclude these cavities from the canal through which the cud passes."

Sir Everard Home having stated that John Hunter did not give credit to the assertion that the Camel can retain a quantity of water in its stomach unmixed with the food, and capable of being recovered after the animal has been killed, the following note by Dr. Patrick Russell, in the Appendix to his brother's 'History of Aleppo,' is of some interest:—"That water, in cases of emergency, is taken from the stomach of camels, is a fact neither doubted in Syria nor thought strange. I never was myself in a caravan reduced to such an expedient; but I had the less reason to distrust the report of others, particularly of the Arabs, seeing that even the love of the marvellous could in such a case be no inducement to invention. It may perhaps be superfluous to produce the authority of an Arab historian (Beidawi), who, in his account of the Prophet's Expedition to Tabuc against the Greeks, relates, among other distresses of the army, that they were reduced to the necessity of killing their camels for the sake of the water contained in their stomachs. (Sale, 'Koran,' p. 164; Gibbon, 'Decline and Fall of the Roman Empire,' v. p. 245.)

"On my return from the East Indies, in 1789, hearing accidentally that my friend Mr. John Hunter had dissected a camel, and was supposed to have expressed an opinion that the animal's power of preserving water in its stomach was rather improbable, I took an opportunity of conversing with him on the subject, when (to the best of my recollection) he told me that 'he by no means drew any such absolute inference from his dissection; that he saw no reason for assigning more than four stomachs to the camel, though he could conceive that water might be found in the paunch little impregnated by the dry provender of the desert, and readily separating or draining from it.'

"In hopes that other particulars might be found among the papers of my lately-deceased friend, I applied to his brother-in-law, Mr. Home, who informed me that he had examined them, but without discovering any observations on the subject." (Vol. ii. p. 425.)

"From these remarks, then, it appears that the small cavity regarded by Daubenton as analogous to a reticulum, was not considered by Mr. Hunter as of sufficient importance to be ranked as a distinct stomach; and the water-bag must therefore, in his opinion, have held the place of the honey-comb-bag in the horned ruminants. And when we compare the relation of the reticulum to the rumen in that tribe, with the corresponding free communication which subsists between the water-bag and rumen in the camel tribe; and when also we observe in both the precise correspondence in the mode of communication of those two cavities with the œsophagus and with the muscular apparatus destined to convey the re-masticated food beyond their apertures into the third cavity, and at the same time find an approach to the peculiar disposition of the cells of the water-bag in the reticulum of some of the horned ruminants, it becomes evident that the two cavities are analogous, the reticulum of the camels being modified for its destined functions by the greater development of the secondary cells, by the absence of a cuticular lining, and by the production of the inner layer of the muscular tunic, which forms the apparatus for closing the orifice of the primary cells. The third cavity, therefore, which could not have been recognised as a distinct compartment in the llama, and which undoubtedly receives the re-masticated food in the camel, ought rather to be regarded as a peculiar structure, to which nothing analogous is to be found in the stomachs of the horned ruminants."



Cells of Camel's Stomach, one-ninth of natural size.

Here is represented the muscular arrangement provided for closing the orifices of the cells so as to prevent the food from falling into them. The cells themselves are exposed, bringing into view their bottoms, the muscular conformation of which enables the animal to give out their contents.

The seven callosities on the flexures of the limbs and chest, and the hump on the back, seem perhaps to bear more relation to the necessities of the animal, considered as the slave of man. These callosities are the points whereon the animal rests when it kneels down to receive its burden. The hump, which is a fatty secretion, is known to be absorbed into the system when the animal is pinched for food, thus forming a provision against the casualties of a life ordained to be spent in the desert.

The Camel furnishes the Arab with flesh and milk; of its hair he weaves clothing and even tents; his belt and his sandals are the produce of its hide; and the dung affords him fuel. The soot of this fuel, after having undergone the process of sublimation in closed vessels, produced the sal-ammoniac, or hydrochlorate of ammonia, which was formerly imported from Egypt into this country, where the alkali is now however manufactured in a variety of ways. In the East the hair of the camel is made into cloth. The raiment of John the Baptist was of camel's hair. (Matthew, iii. 4; Mark, i. 6.) It is principally imported into these islands for the manufacture of pencils for the painter. The hair which is the product of Persia is held in the greatest estimation. There are three qualities—black, red, and gray; the black brings the best price, the red comes next in value, and the gray is only valued at half the price of the red. But these uses are mere trifles when compared with the paramount importance of these animals as commercial vehicles, 'ships of the desert,' as they have been poetically termed; for they are the living machines by means of which communication is kept up across the most desolate and frightful deserts, which without some such aid would be entirely impassable by man. These toilsome journies over the most dreary and inhospitable regions, the organisation of the camel and its extreme temperance enable it to perform with comparative ease.

The load of a heavy or slow-going camel in one of the caravans is, according to Major Rennell, from 500 to 600 lbs. weight. The latter is the amount given by Sandys as the ordinary load; "yet," he adds, "will he carry a 1000 lbs. weight." At Pisa the burden of a full-grown camel is stated to be sometimes 14 kilogrammes (above 800 lbs.). The mode of training the beast to bear these loads seems to vary. Brue, speaking of an African mode (Senegal) towards the end of the 17th century, says:—"Soon after a camel is born the Moors tie his feet under his belly, and having thrown a large cloth over his back, put heavy stones at each corner of the cloth, which rests on the ground. They in this manner accustom him to receive the heaviest loads." Santi describes the method adopted at Pisa. At the age of four years a camel which is intended for labour is broken in. The trainers first double up one of his four legs, which they tie fast with a cord; they then pull the cord, and thus usually compel the animal to fall upon his bent knee. If this does not succeed they tie up both legs, and he falls upon both knees, and upon the callosity which is upon his breast. They often accompany this operation with a particular cry and with a slight blow of a whip. At this cry and blow, with the addition of a sudden jerk downwards of his halter, the camel gradually learns to lie down upon his belly, with his legs doubled under him, at the command of his driver. The trainers then accustom him to a pack-saddle, and place on it a load at first light, but increased by degrees as the animal advances in docility, till at last, when he readily lies down at the voice of his driver and as readily rises up with his load, his education is so far complete. The camels at Pisa, it appears, do not complain if too heavily laden; but in Egypt, according to Denon, they remonstrated loudly on such occasions, crying out when they were laden too heavily or unequally.

In travelling with a caravan the acute sense of smelling possessed by the Camel is strikingly displayed. When apparently completely worn out, and when all have been on the point of perishing with thirst, he has been known to break his halter and run with unerring certainty to a spring which had escaped the observation of the other quadrupeds of the caravan, and of man himself.

Arabia, Persia, the south of Tartary, some parts of India, and Africa, from Egypt to Mauritania, and from the Mediterranean to the river Senegal, appear to be the countries over which the Arabian Camel is principally distributed. It is also numerous in the Canary Islands. That it was a native of Asia from the earliest times, and the great oriental commercial vehicle of ancient as it is of modern days, cannot be doubted. We trace it repeatedly in the Scriptures. Thus when Joseph's brethren had cast him into the pit, and after the commission of their crime had sat down to eat bread, "they lifted up their eyes and looked, and, behold, a company of Ishmaelites came from Gilead, with their camels bearing spicery and balm and myrrh, going to carry it down to Egypt." (Genesis xxxvii. 25.) Again, in Judges, viii. 21, we read that "Gideon arose and slew Zebah and Zalmunnah, and took away the ornaments that were on their camels' necks." In Genesis xxxii. 7, we find that Jacob "divided the people that was with him, and the flocks, and herds, and the camels, into two bands;" and the domestic state of the animal at this early period is further proved by verse 15 of the same chapter, where we see, as part of the present sent by Jacob to propitiate Esau, "thirty milch camels with their colts." In Leviticus, xi. 4, the camel is enumerated among the forbidden animals, "because he cheweth the cud, but divideth not the hoof: he is unclean unto you." Part of Job's "substance (Job i. 3.) consisted of three thousand camels;" and the third messenger of evil informs him (i. 17) that "the Chaldæans made out three bands, and fell upon the camels, and have carried them away." When, after his afflictions, the Lord blessed the latter end of Job more than his beginning (xlii. 12) "six thousand camels" formed a portion of the blessing. And here we may observe that though the inquiry has been the subject of much research, there is no satisfactory evidence of the existence of the Camel in an originally wild state at any period whatever. Diodorous and Strabo indeed mention its existence in such a state in Arabia; and Desmoulins, who has written most valuably on the subject, asserts that it so existed in the time of Hadrian; the natives too of Central Africa maintain, it is said, that the animal is to be found wild in the mountains where Europeans have never penetrated. But it is far from improbable that these wild camels might, like the wild horses of the American prairies, have owed their parentage to camels which had escaped from the control of man. Cuvier, in relating the report of Pallas upon the evidence of the Bucharians and Tartars that there are wild camels in the deserts of the middle of Asia, well remarks that it must not be forgotten that the Calmucks give liberty to all sorts of animals from a religious principle.

In Europe, Pisa seems to be the only locality where the Camel is now bred. At San Rossora, the arid plains and stunted bushes bear some distant resemblance to the Asiatic and African desert; but most authors who understand the subject agree in considering that the race is fast degenerating. The time of their introduction into Tuscany is not accurately known.

The Arabian Camel was introduced into Spain by the Moors; and the southern districts possessed many of these animals for a considerable period after the conquest of Granada; but they are now no longer to be found as a species in the Spanish territory. After the conquest of Spanish America an attempt was made to introduce them into that country by Juan de Reinega, a Biscayan; and Acosta saw them towards the end of the 16th century at the foot of the Andes. But the introduction of these animals was looked upon with no favourable eye by the ruling Spaniards, and they gradually dwindled away. They have however been lately imported with greater success from the Canary Islands. Humboldt mentions them, and particularly some that he saw feeding under a palm-tree near New Valencia.

Camelus Bactrianus (Linn.), the Mecheri, or Camel. It is the *C. Ditophus* of Walther, *C. Turcicus* of Alpinus, the Bactrian Camel of Pennant, Le Chameau of Buffon, the Trampelthier of Knorr. It has two humps on the back. Length about 10 feet. Hair shaggy, particularly under the throat. Colour generally dark-brown. Localities, Persia, Turkey, &c.

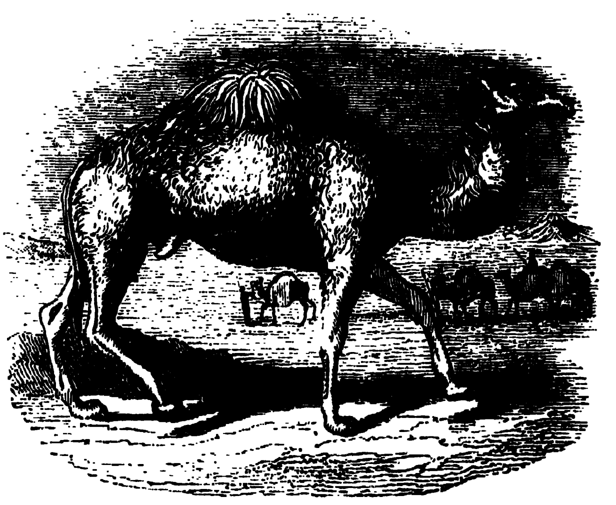
Bactrian Camel (*Camelus Bactrianus*).

This species is comparatively rare; but in the middle zone of Asia, north of the Taurus and the Himalaya Mountains, it is found in comparative abundance. Not that it is not to be seen occasionally in other countries—in Arabia, for instance; but such instances are said to be uncommon. The Bactrian Camel is stouter and more muscular than the Arabian species, and his strength is in proportion. "It varies from brown to white, and also greatly in size, strength, and quickness, according to the breed and climate." (Gray.)

C. Dromedarius (Linn.), the Sghimel, or Dromedary. It is the *C. Luk* of Eversmann, *C. vulgaris* of Forskal, *C. monotophus* of Walther, *C. Dromas* of Gesner, *C. minimus* of Klein, *C. vetus* of Frisch, the Arabian Camel of Pennant, and Le Dromedaire of Buffon.

It has one hump, situated on the middle of the back. Length about 8 feet. Hair pale brown. Localities, Arabia, Africa, &c.

Purchas (book vi., c. 1, s. 9) says that of Camels there are three kinds; the first called Huguin, of tall stature and able to carry a thousand pounds weight; the second less, having a double bunch, fit for carriage and to ride on, called Becheti, bred only in Asia; the third sort, called Raguahill, small, able to travel (for they are unfit for burdens) above an hundred miles in a day. The king of Timbuctoo can send messengers on such camels to Segelmesse or Darha, 900 miles distant, in the space of eight days at the farthest. He further states that such enduring swiftness would be almost incredible, were it not corroborated by the best authorities, who all agree in their accounts of the speed of the Heirie, El Heirie, or Maherry of the desert—Purchas's Raguahill. "When thou shalt meet a heirie," say the Arabs in their poetical mode of expression, "and say to the rider 'Salem Aleik,' ere he shall have answered thee 'Aleik Salem,' he will be afar off, and nearly out of sight, for his swiftness is like the wind."



Dromedary (*Camelus Dromedarius*).

The 'Sabayce,' said to be the fastest breed of the swift Dromedary, will, it is asserted, perform a journey of thirty-five days' caravan travelling (about 18 miles a day) in five days, performing 630 miles in that small period of time. Riley often travelled on a dromedary at the rate of 7 or 8 miles an hour for nine and ten hours a day; and Lyon says that the Maherry of the Northern African Arabs will continue at a long trot of 9 miles an hour for many hours together.

Besides the swift variety above alluded to, the species varies in colour, like the Bactrian, being sometimes cream-coloured or even white. There are specimens in the Gardens of the Zoological Society in the Regent's Park.

The natural family of the *Camelidæ* comprises also the South American form so well known by the name of *Llama*. [LLAMA.]

A fossil species, *C. Sivalensis*, of this genus was discovered by Dr. Falconer and Captain Cautley in the Tertiary deposits of the Sewalik Hills of Hindustan. The crania, jaws, and teeth of this species are to be seen in a fine state of preservation in the British Museum. It was nearly related to the existing species, but exceeded them by at least one-seventh in height.

CAMERARIA, a genus of plants belonging to the natural order *Apocynaceæ*. *C. latifolia* is called the Bastard Manchineel-Tree in the countries where it grows, on account of its possessing properties similar to the Manchineel. The true Manchineel is the produce of *Hippomane Manchinella*, one of the Spurgeworts. [HIPPOMANE.]

CAMOMILE, or CHAMOMILE. [ANTHEMIS.]

CAMPA'NULA (diminutive of *Campana*, a bell, on account of the form of its flowers), a genus of plants the type of the natural order *Campanulaceæ*. It has a 5-cleft calyx, the corolla mostly bell-shaped, with five broad and shallow segments, the anthers free, the filaments dilated at the base, the stigma 3-5-fid, the capsule not elongated, 3-5-celled, and opening by lateral pores outside the segment of the calyx. This genus is one of the largest in the vegetable kingdom, although from time to time the number of its species has been reduced by the formation of new generic types. Eight species are described by Babington as British. The species of Smith were more numerous, but Babington recognises Heister's genus *Specularia* for the old *C. hybrida* (*Prismatocarpus hybridus* of L'Heritier) and its allies, and Schrader's genus *Wahlenbergia* for the *C. hederacea*. The older names of the genus *Campanula* are *Trachelium* and *Cervicaria*, names which were given to it on account of the supposed efficacy of many of the species in the cure of disorders of the neck and trachea. Hence also the common name Throatwort. All the species are herbaceous, with mostly perennial roots, and the radical leaves differing in form from those of the stem. They are natives of the northern hemisphere.

C. edulis, Chobs, Okab, is a hispid plant with a thick root, erect 1-flowered stems, ovate-lanceolate crenate leaves; lobes of the calyx linear-lanceolate, equal in length to the corolla, which is hispid. It is a native of Arabia Felix. Its root is thick and sapid, and contains a considerable quantity of starch. It is on this account frequently eaten by children, as are the roots of many other species.

C. glomerata, Clustered Bell-Flower, has the leaves minutely crenate-serrate, the lowermost stalked, ovate-lanceolate, generally cordate at the base, the upper leaves half-clasping, sessile, ovate, acute; the flowers sessile in terminal and axillary clusters. This is a native of Europe, especially in mountainous districts. In Great Britain it is found in dry pastures on limestone. It is the *Trachelium minus* and *Cervicaria minor* of Lobel and Dodonæus. It is often cultivated in our gardens, and a great number of wild varieties have been described by Alphonse De Candolle.

C. Trachelium, Nettle-Leaved Bell-Flower, has the leaves coarsely doubly serrate, hispid, the lower one cordate, with long stalks, upper nearly sessile, ovate or lanceolate, acuminate; flowers racemose, peduncles 2-3-flowered; segments of the calyx triangular-lanceolate, entire, erect; the stem erect, angular. This is a European species. It is found in the south of England, and has large blue bell-shaped flowers. A decoction of this herb was formerly used in disorders of the throat, but the properties of the genus are medicinally inert.

C. rotundifolia, Hare-Bell, Blue-Bells, Milkwort, has the radical leaves cordate or reniform, shorter than their stalks; stem-leaves linear, the lower ones lanceolate; flowers one or more racemose, corolla turbinate, campanulate. It has pretty blue flowers, and is a favourite throughout Europe. In France it is called Clochette; in Germany Weissen-Busch, and Grassglas. The juice of the flowers makes a very good blue ink, and when mixed with alum a green one. The roots of this species also may be eaten.

C. pyramidalis is a glabrous plant with leaves glandular, toothed, the lower ones petiolate, ovate-oblong, somewhat cordate, the stem-leaves sessile, ovate-lanceolate; the flowers numerous, pyramidally racemose, the lobes of the calyx acuminate, spreading, the capsule spherical, deeply furrowed. It is indigenous on rocks and walls in Carinthia, Carniola, and Dalmatia. From its having been a great favourite in the gardens of Europe, it has now become naturalised in many places where it was not originally a native. It has not often been found wild in Great Britain, though it is commonly cultivated for the sake of its tall raceme of beautiful blue flowers. It is in great demand in Holland, where it is employed to ornament halls and staircases, and to place before fire-places in summer, for which purpose it is planted in large pots and trained in a fan-manner so as to hide a large surface. In the shade it remains in bloom two or three months. "The art of producing a very large plant is to begin with pots of a small size, and shift frequently during two years, till at last the plant occupies a pot of a foot or more in diameter. Rich light soil should be used, but no animal manures or recent dung, as these are very injurious. Cuttings of the roots flower the second and seedlings the third year. *C. carpatica* and *C. grandiflora* may be treated in the same manner." (Loudon.)

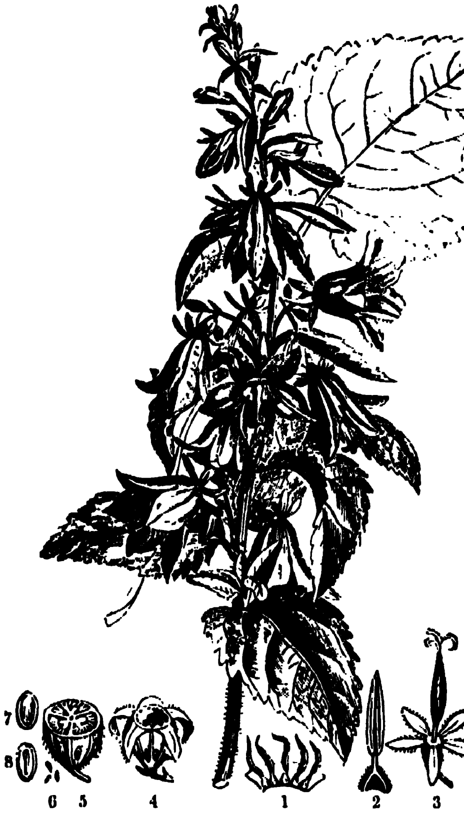
C. Rapunculus, Rampion, has leaves crenate, the radicle leaves oblong-elliptical narrowed into a petiole, the stem-leaves linear-lanceolate, sessile, the raceme few-flowered, the segments of the calyx lanceolate. It is a native of Marocco and Barbary, also of the south of Europe, and extends as far north as Norfolk in England. It has a fusiform thick white root, which looks like a little turnip; hence the specific name *rapunculus*, being the diminutive of *rapa*, or radish. In Germany it is called Rapunzel, in France Raiponce, in Italy Raperonzola; the English Rampion appears to be the same word. It is much cultivated in France and Italy, and sometimes in Britain, for the sake of the roots, which are "boiled tender and eaten hot with sauce, or cold with vinegar and pepper." (Loudon.) In its cultivation the seed should be sown in the spring on deep light soils, in drills; and in the autumn of the year the plants will be ready for use. The *C. persicifolia*, a doubtful native of Britain, and the *C. Rapunculoides*, an indigenous plant, may be used for the same purposes as *C. Rapunculus*.

C. lilifolia (*Adenophora lilifolia*, Ledebore) has alternate leaves, the radical ones petiolate, ovate-roundish, cordate, toothed; the corolla campanulate, the style exserted. It is a native of Siberia, and of the east of Europe. Like many others of the genus it has an edible root, which is sometimes divided into several turnip-formed tubers. The flowers are numerous and sweet-scented. It is interesting from the fact that the leaves before blossoming are crowded together on the summit of the stem, so as to form a green rose-like body. But as the axis elongates, the leaves become afterwards scattered on the prolonged stem. The roots are eaten in China both raw and cooked.

The other British species of this genus not described are *C. latifolia*, Great Bell-Flower, common in the North; *C. Rapunculoides*, very rare; and *C. patula*, frequent in hedges and thickets. [SPECULARIA; WAHLENBERGIA.]

(Loudon, *Encyclopædia of Plants*; Koch, *Flora Germanica*; Babington, *Manual of British Botany*; Burnett, *Outlines*; Don, *Gardener's Dictionary*.)

CAMPANULA'CEÆ, *Bellworts*, the Campanula Tribe, a natural order of Monopetalous Dicotyledonous Plants, the character of which is to have an inferior three or more celled fruit containing many minute seeds, combined with a regular corolla, distinct stamens equal in number to the lobes of the corolla, dilated bases to the filaments, a downy style, and a milky juice. It consists of plants usually herbaceous, sometimes shrubby, scattered over all parts of the globe, but most abundant in the form of species related to the common *Campanula*, or Bell-Flower, in the milder parts of Europe and Asia. Of 500 species only 19 are found within the tropics. The flowers are commonly blue, purple, or white, occasionally rose-coloured, very rarely yellow, as in a Canary shrub called *Musschia aurea*. None of the species are poisonous, notwithstanding that the order is very closely allied to the dangerous *Lobeliaceæ*, which hardly differ except in having irregular flowers and syngenesious stamens. The affinities of this order are with *Compositæ* through *Lobeliaceæ*, and also with *Solanaceæ* and *Vacciniaceæ*. It embraces 28 genera and about 500 species.



Rampion (*Campanula Rapunculoides*).

1, The base of the corolla, with the stamens; 2, a stamen separate; 3, a calyx with the style and stigma; 4, a ripe seed-vessel; 5, a section of the same; 6, seeds natural size; 7, a seed magnified; 8, a section of the same.

CAMPANULARIA. [Polypiaria.]

CAMPHOR is a substance produced by several plants, and in its chemical characters belongs to the class of Vegetable Oils. It is yielded in greatest abundance by the natural order *Lauraceæ*, from several species of which Camphor might be produced. It is however obtained for commercial and medicinal purposes from the *Camphora Officinarum*, Nees (*Laurus Camphora* of Linnæus). A substance called Borneo Camphor, having similar properties to that from the natural order *Lauraceæ*, is obtained from the *Dryobalanops Camphora*. This Camphor does not come into Europe on account of the great demand for it in the Chinese markets. [Camphor, *Medical Uses of*, in Arts and Sc. Div.]

CAMPHOR-OIL, a substance obtained in Borneo and Sumatra from the *Dryobalanops Camphora*. It is supposed to be Camphor in an imperfect state of formation. [Dryobalanops.]

CAMPHORA, a genus of plants belonging to the natural order *Lauraceæ*. This genus was constituted by Nees von Esenbeck for the *Laurus Camphorifera* of Kämpfer, the plant which yields the Camphor of commerce. It is known by its hermaphrodite panicled naked flowers; 6-cleft papery calyx, with a deciduous limb; 9 fertile stamens, 3 in a row, the inner row with two stalked glands at their base; the anthers 4-celled, the outer turned inwards, the inner outwards; the fruit placed on the obconical base of the calyx; the leaves triply nerved, glandular in the axils of the principal veins; the leaf-buds scaly.

C. officinarum, the Camphor Laurel, is a tree with lax smooth branches; the leaves are bright-green and shiny above, paler beneath, and somewhat coriaceous, with a sunken gland at the axils of the principal veins, projecting at the upper side, opening by an oval pore beneath. This plant is a native of Japan and China, and is cultivated in most of the warmer parts of the world. The Camphor of commerce is yielded by this tree, which is cultivated most extensively in the island of Formosa, from whence it is taken to Canton, which is the principal market for Camphor.

CAMPION. [Lychnis; Silene.]

CAMPONTIA, a genus of supposed Marine Annelides, first described by Dr. Johnston. Of this genus Dr. Johnston says, "When I first described this animal its close resemblance to some caterpillars was particularly mentioned, but the suspicion of its being actually a larva did not occur to me; for I believed it to be an established fact among entomologists that no insect passed its preparatory stages in sea-water. I have been informed however that Mr. M'Leay, and no higher authority can be given, has proved that the worm in question is the larva probably of some dipterous fly; and if this opinion be correct (which its anatomy strongly confirms), then it will follow that at least one larva naturally lives and undergoes its changes in the sea—a conclusion which I think is one of some importance, and at variance with our present notions. Our *Campontia cruciformis* may be found at all seasons at the roots of sea-weed and corallines in pools left by the recess of the tide. The very specimens before me were procured by myself a few days ago in parts to which no fresh-water could have access, and which are covered to the depth of several feet every tide, for they are near low-water mark." (*Mag. Nat. Hist.* vol. viii.)

CA'MPSIA (Lepeletier and Serville), a genus of Coleopterous Insects, of the section *Heteromera*, sub-section *Stenelytra* (Latreille), and family *Helopidæ*. [Helopidæ.]

CAMPTO'CERUS (Dejean), a genus of wood-feeding Coleopterous Insects, belonging to the section *Xylophagi* of Latreille. [Xylophagi.]

CAMPTODO'NTUS (Dejean), a genus of Coleopterous Insects, of the family *Scaritidæ*, closely allied to *Oxystomus;* from which genus however the present is distinguished by the species having the labial palpi shorter than the external maxillary: antennæ with the basal joint scarcely longer than the two following joints taken together. [Scaritidæ.]

CAMPYLOMY'ZA (Wiedeman), a genus of Dipterous Insects, of the family *Tipulidæ*. It has the following characters:—Proboscis curved; antennæ filiform, 14-jointed, two basal joints tolerably thick, the remaining short, cylindrical, and covered with fine hairs; body short; femora elongated; wings hairy, with one marginal cell, and three posterior cells, the first and second divided by an indistinct nervure.

The species of this genus are all extremely minute, and found on the leaves of trees.

C. bicolor is less than one-twelfth of an inch in length, of a blackish colour, with the edges of the abdominal segments pale; legs pale-yellow. This species and three or four others inhabit this country.

CA'MPYLUS (Fischer), a genus of Coleopterous Insects, belonging to the family *Elateridæ*. The species of this genus are distinguished by their having the hinder part of the head free, or not sunk into the thorax as far as the eyes, as is usually the case in this tribe. The eyes are globular and projecting: the antennæ are rather long, obscurely pectinated, and inserted close to the eyes beneath a projecting frontal ridge; thorax narrow; elytra much elongated, and somewhat linear.

C. dispar, a common insect in this country, is found on the leaves of trees, and on nettles and other plants. It is nearly half an inch long, and of an ochreous colour, with the under part of the body more or less black: sometimes the posterior part of the head, the disc of the thorax and elytra, and the femora are black.

About six or seven species of this genus have been discovered, most of which are European. The above-described species is the only one known to inhabit England.

CAMWOOD (German, Kammholz; French, Bois de Cham; Portuguese, Pao Gabão), a red dye-wood, the colouring matter of which is similar to that of Nicaragua or Peach-Wood. It is the produce of a plant belonging to the natural order *Leguminosæ*, called *Baphia nitida*. It is used with alum and tartar as a mordant. It does not afford more than a third part of the colouring matter yielded by an equal quantity of Brazil-Wood. It is used likewise by turners for making knife-handles, and by cabinet-makers for ornamental knobs to furniture. The greatest part of the Camwood imported into Europe is brought from Sierra-Leone.

CANARIUM, a genus of plants belonging to the natural order *Amyridaceæ*. *C. commune* yields a gum which is said to have the same properties as the Balsam of Copaiva. The fruit, which is a three-cornered nut, is eaten in Java both raw and dressed; and an oil is expressed from them which when fresh is eaten at table, and when stale is used for burning in lamps. The raw nuts are apt to bring on diarrhœa.

CANARY-BIRD, or CANARY-FINCH, Le Serin de Canarie of the French, Der Canarienvogel of the Germans, Canario of the Italians, the Canary of the English, *Fringilla Canaria* of Linnæus. This bird is the well-known songster which is to be found caged in every house where the inmates are fond of song-birds. The Canary Islands are the most frequented haunts of the species. In the wild state the prevailing hue, according to the observations of Adanson, Labillardière, and others, is gray or brown, mingled however with other colours, but never reaching the brilliancy of plumage exhibited by the bird in captivity—a brilliancy arising from long domestication and repeated crosses with analagous species. Its introduction into Europe is stated by some to have taken place in the 14th century; but Bechstein names the beginning of the 16th. "The arrival," says the author last quoted, "of the canary in Europe, is thus described:—A vessel which in addition to its other merchandise was bringing a number of these birds to Leghorn, was wrecked on the coast of Italy, opposite the island of Elba, where these little birds, having been set at liberty, took refuge. The climate being favourable they increased, and would certainly have become naturalised, had not the wish to possess them occasioned their being caught in such numbers that at last they were extirpated from their new abode. From this cause Italy was the first European country where the canary was reared. At first their education was difficult, as the proper manner of treating them was unknown; and what tended to render them scarce was that only the male birds were brought over,—no females. The gray of its primitive colour, darker on the back and greener on the belly, has undergone so many changes from its being domesticated, from the climate, and from the union with birds analogous to it (in Italy with the citril-finch, the serin; in our country—Germany—with the linnet, the greenfinch, the siskin, and the goldfinch), that we now have canaries of all colours. If we had not sufficient proof that canaries came originally from the Fortunate Islands, we should think the citril-finch, the serin, and the siskin were the wild stock of the domesticated race. I have seen a bird whose parents were a siskin and serin, which perfectly resembled a variety of the canary which is called the green. I have also seen mules from a female gray canary, in which was no trace of their true parentage. The gray, the yellow, the white, the blackish, and the chestnut are the principal varieties, and it is from their combination and from their tints that we derive the numerous varieties that we now possess. Those canaries that have the upper part of the body of a dusky green or linnet-brown, and the under part the yellowish-green of the green-bird, with dark brown eyes, are the strongest, and most nearly resemble the primitive race. The yellow and white often have red eyes, and are the most tender. The chestnut are the most uncommon, and hold a middle rank for strength and length of life between the two extremes. But as the plumage of the intermediate ones is a mixture of these principal colours, their value depends on the pretty and regular manner in which they are marked. The canary that is most admired amongst us now is one with the body white or yellow, the head, particularly if crested, wings, and tail, yellowish-dun: the second in degree is of a golden yellow, with the head, wings, and tail black, or at least dusky gray. Next follow the gray or blackish, with a yellow head and collar; and the yellow, with a blackish or green tuft, which are very much valued. As for those that are irregularly spotted, speckled, or variegated, they are much less sought after, and are used to pair with those of one colour, white, yellow, gray, brown-gray, and the like."

The usual length of a Canary is about 5 inches, of which the tail measures about two and a quarter. The bill is about 5 lines in length, strong, sharply pointed, and inclining to white. The shanks, or feet as they are technically called, are about 8 lines long, and of a flesh-colour.

The female is very like the male, but is generally less bright in colour, smaller about the head, shorter about the neck and body, not so high on the shanks, and altogether of a form somewhat less elegant than that of the male. There is a bean-shaped feather under the bill, and the temples and circles round the eyes are deeper in colour than the other parts of the body.

The Canary breeds freely with allied species of birds, and many hybrids are recognised by breeders. Amongst the more common are the following:—

1. Mules bred from a hen Canary and a Goldfinch.—These partake of the parental colours on both sides. The finest are produced from yellow or white hen canaries.

2. Mules bred from a hen Canary and a male Siskin.—The young always resemble the Siskin in shape. If the mother be green they will be like a hen Siskin; if she be white or yellow they will be lighter in colour than a Siskin, without however any great difference.

3. Mules bred between a hen Canary and a Green-Bird, or a Citril-Finch.—When the mother is neither white nor yellow the young do not differ much from the Gray or Green Canary; but they are generally rather more slender, and their bills are also shorter and thicker.

4. Mules bred between a hen Canary and a Linnet.—These, if the mother be white or yellow, will be speckled; if she be gray they will resemble her generally, but their tails will be longer.

Most of these mules are fruitful, and there is no great difficulty in getting the parents to pair; but when the union is with species more remote, the difficulty increases in proportion.

5. Mules between a hen Canary and a Bullfinch.—Bechstein says that the eggs of this union seldom prove fruitful; but Dr. Jassy of Frankfort obtained mules of a bullfinch and a canary, by making other canaries sit on the eggs and bring up the young, a plan pursued in Bohemia.

Besides the birds above enumerated, chaffinches, yellowhammers, &c. have been tried, but with no good success. Bechstein says that he never saw a male canary very fond of a female yellowhammer, nor a male of the latter kind of a female canary, though the plumage may be selected so as to offer a striking resemblance.

It will be observed that in all the five instances recorded the Canary is always the mother. The reason why breeders select the male of the other species when mules are desired is, because a female siskin, goldfinch, &c. could not easily be induced, if at all, to lay her eggs in an artificial nest like a canary.

The hybrids between these various species are stated to be fruitful, and to have the power of continuing their mixed forms. The first eggs of these hybrids are said to be very small, and the young hatched from them very weak. The eggs of the next year are said to be larger, and the nestlings stronger and stouter.

In order to obtain bright and good plumage, those birds whose colours are clear and whose spots are clean and well defined should be placed together. A brownish-gray or greenish bird paired with one of a lively yellow often produces young of a dim white and of other admired colours. Two crested birds should never be joined, for their offspring are frequently hatched with part of the head bald, or otherwise deformed in plumage.

Bechstein gives the following directions for forwarding the breeding of Canaries:—"The best time for pairing canaries is the middle of April. Either one male and one or two females are placed in a large cage, or many of both sexes are united in a room or aviary, having the advantage of a south aspect. Nests made of turned wood or osiers are given them, as straw ones are too easily torn. It is a good plan to place in the room or aviary slips of pine, which being cut in February do not lose their leaves. If a little inclosure of wire-gauze can be fixed over the window, where the birds can enjoy the fresh air, nothing will more effectually contribute to render the young healthy and robust. Birds which are to be paired for the first time should be previously placed in the same cage for seven or eight days, in order to become acquainted and accustomed to live together. If two females are to be caged with one male, it is especially necessary that they should be together long enough to leave off quarrelling, and the pairing-cage should be divided into two equal parts, communicating by a sliding-door. This being done, a lively male and one of the females should be placed in the first division; as soon as she has laid the male should be moved into the other division, the door of separation being shut; but as soon as the other has also laid the door may be left open: the male will then visit the females alternately, and they will not trouble themselves about each other; but without those precautions jealousy would incline them to fight and destroy each other's eggs. When it is intended to place a great many females, double or treble the number of males, in a room or aviary, the latter should always be first paired with a single female, which will ever after remain the favourite; and it will only be when she is about to sit that he will pair with the others; and this is all the notice he will take of them, for afterwards he will only notice their young. It is from these mothers however that the most and the best birds are generally procured. If the floor of the room or aviary is well covered with moss, little else need be added for making the nests, otherwise they should be supplied with the hair of cows and deer, hog's bristles, fine hay, lint, wool cut two or three inches long, paper-shavings, and the like. That which is coarsest serves for the outside, and the softest and finest for the inside. If they have shrubs, traces of the natural instinct of the canary are soon observed in the nests, which they construct without the help of the turner or basket-weaver; but they are of an inelegant form, and the outside is not very carefully finished. The females alone, as is usual among birds, are the builders, the males only choosing the situation and bringing the materials. It is in the nest, where the female is in continual motion, that the pairing takes place; she invites the male by constant little chirpings, repeated more quickly the nearer she is to laying. Seven or eight days are generally reckoned from the first pairing to the laying of the first egg; the other eggs, whose number varies, without exceeding six, are laid successively every following day, and often at the same hour. The laying ended, pairing continues during the first days of incubation. If the pairs agree they must be left entirely to themselves, without endeavouring to use art to help nature, as many do. It is usual to take away the first egg and substitute an ivory one, which is repeated with the others to the last, preserving them in the meantime in a box filled with fine dry sand: they are afterwards restored all together to the nest to be hatched."

Upon this practice there is a difference of opinion, as the plan above recommended causes the mother a greater loss of heat, and burdens her at once with five or six little ones, which coming together disturb rather than please her; whereas in seeing them hatched successively one after the other her pleasure is increased, and her strength and courage are supported. "Very intelligent bird-fanciers," adds Buffon, "assure us that by not removing the eggs from the female, and leaving them to be hatched in succession, they have always succeeded better than when they have substituted ivory eggs." The hen Canary will generally lay three or four times in the year, from April to September, and some will even continue to lay during their moult. The eggs are of a delicate sea-green hue, spotted at one end more or less with violet or maroon colour. About the eighth day after the hen has begun to sit, the eggs may be examined by holding them between the flame of a candle and the eye. Those which are good will by that time exhibit well-developed blood-vessels, whereas the bad ones will continue clear or be already addled—these should be thrown away. It may be doubted however whether the better course be not to leave the hen quite undisturbed. The cock will sometimes take his turn for some hours in the day; but the hen seldom approves of this: as soon as she has taken her hasty meal she flies back to the nest, and if the male, whose capabilities as a hatcher she seems strongly to question, do not retire, she pecks him till he does. On the thirteenth day the young generally make their appearance. While incubation is going on the place where the birds are confined should be kept quiet; for it is asserted that sudden jarring noises, such as the violent slamming of a door or the discharge of a gun will kill the young in the shell. We have above seen that it is usual to give two females to one male; and it is alleged that if one of the former should die during incubation, the survivor immediately takes charge of the eggs, to the care of which she so entirely devotes herself that she repels the caresses of her mate, whose solace she was while the deceased was sitting.

As soon as the young break the shell, two jars should be placed near the feeding-trough. In one of these there should be a quarter of a hard egg, yolk and white together, chopped very fine, with a bit of crumb of white bread or biscuit, which has been soaked in water, and afterwards well pressed to get out the moisture. In the other jar rape-seed, well boiled and then washed in fresh water, should be placed; great care must be taken not to let this food become sour, which would destroy the nestlings. The cock-bird is the principal nurse after hatching.

It is sometimes necessary to bring up the young by hand, and then a paste should be made of white bread or biscuit pounded very fine, rape-seed well bruised, a small quantity of the yolk of an egg, and water. The nestlings must be fed with a quill cut into the shape of a spoon, and should not have less than ten or twelve meals a day; four beaksful well piled up on the quill constitute a meal. On the thirteenth day they will begin to feed themselves, and in four weeks they may be removed to other cages. Care however must be taken to supply them for some time with the paste above described, together with the food of full-grown birds, as a sudden privation of the former has been known frequently to occasion death; especially if the nestlings are deprived of it when moulting.

Mr. Rennie says, "It sometimes happens in very dry seasons that the feathers of the young birds cannot develop naturally; a bath of tepid water, employed on such an occasion by Madame ——, was so successful, that I cannot do better than recommend it. The same lady succeeded equally well in similar circumstances in hatching late eggs; she plunged them for some minutes in water heated to the degree of incubation, and immediately replaced them under the mother; in a short time she enjoyed the pleasure of seeing the little ones make their appearance. This interesting experiment may be applied to all sorts of birds, and may be particularly useful in regard to those of the poultry-yard."

About the thirteenth or fourteenth day, by which time the nestlings can eat alone, the males begin to warble and so do some of the females, but in a more disjointed style. The males, which may then be easily distinguished, should be forthwith separated, each bird being placed in a cage by himself (which must be first covered with a piece of linen and afterwards with a darker curtain) apart from every other bird, in order that his education may begin, if it is intended that his natural song should be superseded by an artificial melody; if he is left unseparated beyond the fourteenth day he will retain a portion of his father's song, and murder his acquired melody by intermingling the paternal notes. His musical lesson must be repeated five or six times in the day, especially in the morning and evening, his master performing the desired air either on a flageolet or a bird-organ; but, as has been observed in the case of the bullfinch, if the instrument be not in perfect tune the whistling of a man of taste is infinitely preferable. From two to six months, according to the memory and the abilities of the scholar, will be spent in this musical education. Some canaries have been thus taught to repeat correctly two or three airs, and others have learned to pronounce distincly a few short words; for they possess great quickness and correctness of ear, and have excellent memories.

When the more natural song is preferred, those canaries are most esteemed which introduce into their warblings the notes of the nightingale, wood-lark, or tit-lark, and this may be easily accomplished by placing those birds near the young canaries. The canaries of the Tyrol are more frequently taught to introduce the notes of the nightingale, while those of England more frequently interweave those of the wood-lark. "In Thuringia," says Bechstein, "the preference is generally given tó those which, instead of a succession of noisy bursts, know how, with a silvery sonorous voice, to descend regularly through all the tones of the octave, introducing from time to time the sound of a trumpet. There are some males which, especially in the pairing season, sing with so much strength and ardour, that they burst the delicate vessels of the lungs and die suddenly."

Canaries may be made to sing in the night—some do this of their own accord. The tuition must commence early in their youth by covering the cage, and thus keeping them in the dark during the day long enough for them to be hungry; they are thus brought to feed by candle-light, and at last sing. The hen birds will also sing, particularly in the spring, but in an unconnected style. Old hens past breeding will often sing in this way the year round.

There are societies in London for promoting the breeding of Canaries, and amateurs distinguish upwards of thirty varieties.

Mr. Rennie mentions two sorts of Canaries, "the plain and variegated, or as they are technically called, the gay spangles or mealy, and jonks or jonquils. These two varieties are more esteemed than any of the numerous varieties which have sprung from them; and although birds of different feathers have their admirers, some preferring beauty of plumage, others excellence of song, certainly that bird is most desirable where both are combined. The first property of these birds consists in the cap, which ought to be of fine orange-colour, pervading every part of the body except the tail and wings, and possessing the utmost regularity, without any black feathers, as by the smallest speck it loses the property of a show bird, and is considered a broken-capped bird. The second property consists in the feathers of the wing and tail being of a deep-black up to the quill, as a single white feather in the wing or tail causes it to be termed a foul bird; the requisite number of these feathers in each wing is 18, and in the tail 12. It is however frequently observed that the best-coloured birds are foul in one or two feathers, which reduces their value, although they may still be matched to breed with." These form the leading features of excellence; but it is generally the custom of the societies above mentioned to award the prize to the competitor who produces a bird nearest to the model published by them the season prior to that wherein the competitors are to show for the prize.

The fullest information on the subject of breeding and treating the Canary will be found in Bechstein's *Cage-Birds*.

CANARY-GRASS. [PHALARIS.]

CANCER, a genus of Short-Tailed *Crustacea*, the type of the family *Canceridæ*. Dr. Leach restricted the genus *Cancer* to the form of *Cancer Pagurus*, Linn., the large eatable Crab of our coasts, which was, when he defined the genus, the only species known. It has the following characters:—

External antennæ with the basilar joint broad, very long and thick, filling the hiatus between the inner canthus of the orbit and the front, and terminating forwards in a strong, angular, tooth-like projection, directed forwards and a little inwards, reaching beyond the frontal line. The terminal or moveable portion is slender, very short, and arises from the internal part of the basilar joint nearer to the cell of the internal antennæ than to the orbit. The internal antennæ, instead of lying obliquely outwards or transversely, as in most other genera of this section, are directed forwards—a character by which *Cancer* may at once be distinguished from *Platypodia*, *Carpilius*, *Xantho*, &c. The second joint of the inner footstalk of the external pedipalps is excavated at the anterior part of the inner margin; in some species the notch is confined to the angle, in others it extends half way down the side of the joint. The first pair of feet is nearly equal; in some specimens of each species the difference in size being scarcely appreciable. They are generally very robust. The remaining feet have no spines, but are in most species more or less hairy. The abdomen of the male has five, and that of the female seven joints.

With the exception of our indigenous species, *Cancer Pagurus*, they are all, as far as their localities are known, exclusively natives of the coasts of the hotter parts of America.

Mr. Bell, in a paper on the genus *Cancer* ('Zool. Trans.' i. 335), gives three new species, namely, *C. longipes*, *C. Edwardsii*, and *C. dentatus*, brought home by Mr. Cuming and Mr. Miller, besides *C. irroratus* of Say, and *C. Pagurus*, which last, as it was considered the type by Dr. Leach, we select as an example.

C. Pagurus is the Great Crab of the English coasts. Mr. Bell gives the following description of it:—Carapace transversely oblong, flattened, but little higher in the middle than at the sides, somewhat rounded before and behind; the surface minutely granulated, smooth, with the regions but slightly marked. Latero-anterior margin slightly recurved, divided into ten quadrate lobes, the sides of which are contiguous and the margins entire; the last lobe inconspicuous, and passing into the posterior marginal line, which terminates immediately anterior to the posterior transverse ridge. Front trifid, the teeth of nearly equal length and size. Orbits round, with a strong triangular tooth over the inner canthus, which does not project so far as the front; and a smaller one filling the space between the two superior fissures. External antennæ with the basilar joint much elongated, and terminating forwards in an obtuse tooth; the first joint of the moveable portion club-shaped, the second cylindrical, the remaining portion setaceous. Internal antennæ directed forwards, the anterior half doubled directly backwards in a state of rest. The basilar joint broad, cup-shaped, its outer edge projecting forwards; the second joint (the first of the moveable portion) cylindrical, the penultimate with a small, hooked, and recurved process at the apex. Padipalps as in the rest of the genus. Sternum minutely punctated, and furnished with small patches or lines of short scanty hair. Abdomen in the male with the margin fringed with short hair; the last joint forming an equilateral triangle. Anterior feet large, robust, smooth, without spines or tubercles, minutely granulated; the hand rounded, without crest, the inner surface exhibiting only the rudiments of the five lines of puncta, so conspicuous in other species of the genus. The remaining feet furnished with numerous fasciculi of stiff hairs, the last joint in all furrowed, and terminated by a short strong nail. Colour above reddish-brown, the legs more red, the claws deep shining black; beneath whitish. Locality, coasts of Great Britain, &c., and of western Europe. Great numbers are annually caught on the coasts of Great Britain. They sometimes attain a large size, weighing ten or twelve pounds.

Pennant states that this species inhabits rocky coasts, and is the most delicious meat of any, and that it casts its shell between Christmas and Easter. "There are some species," says Milne-Edwards, in his article 'Crustacea,' in the 'Cyclopædia of Anatomy and Physiology,' "such as the crabs and the *Brachyura* generally, in which the carapace presents a considerable expansion on either side, forming two large compartments in which the greater mass of the thoracic viscera is contained. Under these circumstances it would be impossible for the animal to escape from its dorsal covering by the relatively inconsiderable opening which this part presents on its inferior aspect. This renders it necessary that the carapace, instead of being cast off by simply rising in a single piece, should give way and separate in some direction or another, and this it does by splitting along the curved lines, extending on either side from the mouth to the origin of the abdomen, in the course of which the epimeral pieces cohere with the dorsal one." (Collinson, 'Phil. Trans.' 1746 and 1751; 'Hist. Nat. des Crustacés,' t. 1, p. 56.) Sir Charles Lyell says ('Principles of Geology'), "A large female crab (*Cancer Pagurus*) covered with oysters, and bearing also *Anomia Ephippium* and *Actiniæ*, was taken in April, 1832, off the English coast. The oysters include individuals of six years' growth, and the two largest are four inches long and three inches and a half broad. Both the crab and the oysters were seen alive by Mr. Robert Brown. This specimen is in the collection of my friend Mr. Broderip, who observes that this crab, which was apparently in perfect health, could not have cast her shell for six years, whereas some naturalists have stated that the species moults annually, without limiting the moulting period to the early stages of growth of the animal."

The genus *Cancer* of Linnæus included a large number of species, and the term Crab, which is a translation of it, is in common parlance applied to the great bulk of the Brachyurous Crustaceans.

For the Blood-Spotted Crab of the Asiatic seas (*Cancer maculatus*, Linn., &c.) and the Coralline Crab (*Cancer corallinus*, Fabr.), Dr. Leach instituted the genus *Carpilius*, characterised by the existence of a single tooth on the border of the carapace, and by the tridentated front; and, for the Eleven-Toothed Crab (*Cancer undecimdentatus*, Fabr.), the carapace of which is smooth, with 11 crenulated teeth on each antero-lateral border, and black toothed fingers, spoon-shaped at the end, he founded the genus *Clorodius* or *Chlorodius*. Milne-Edwards enumerates four species of *Carpilius* and seven of *Chlorodius*. He considers the fossil Crabe aux Grosses Pinces, *Cancer macrochelus*, Desm. ('Hist. Nat. des Crustacés Fossiles,' p. 91, pl. vii. fig. 1-2), *Cancer Lapidescens*, Rumph. ('Amb. Rariteit Kamer,' pl. 60, f. 3), as referrible to the genus *Carpilius* rather than to the division of Crabs properly so called. It should be remembered that Milne-Edwards's genus *Cancer* (Crabe) differs from that of Leach. The former includes under that name such forms as *Cancer roseus* (*Carpilius roseus* of Rüppell), *C. lobatus*, *C. esculptus*, *C. limbatus* (*Xantho granulosus*, Rüp.), *C. Savignii* and *C. Acanthus*, excluding Leach's *Cancer*, the type of which is the eatable Crab of our coasts, to which form Milne-Edwards gives the name *Platycarcinus*. It does not appear that any species of *Cancer*, Leach, *Platycarcinus*, Milne-Edwards, has been found in a fossil state.

CANCROMA. [BOAT-BILL.]

CANDY-TUFT. [IBERIS.]

CANIS, a genus of Carnivorous *Mammalia*, of which the common Dog may be regarded as the type.

Under the Linnæan genus *Canis* are to be found the Dogs (*Canis familiaris*); the Wolves (*Canis Lupus*); the Hyænas (*Canis Hyæna*); the Foxes (*Canis Vulpes*), &c.; the Jackals (*Canis aureus*); the Mexican Wolf (*Canis Mexicanus*), Xoloitzcuintli of Hernandez; and *Canis Thous* of Surinam.

Cuvier arranges under the genus *Canis* Les Chiens, the Dogs properly so called (*Canis familiaris* and its varieties); the Wolves (*Canis Lupus*, *C. Mexicanus*, *C. jubatus*); and the Jackals, Chacal or Loup Doré (*Canis aureus*): and he observes, that the Foxes (which Brisson and others have separated under the name of *Vulpes*) may be distinguished from the Wolves and the Dogs by their longer and more tufted tail; by a more pointed muzzle; by the pupils of their eyes, which by day present a kind of longitudinal slit instead of the round form; by the superior incisors being less lobated (echancrées); and, he observes on their fetid odour, their disposition to dig for themselves earths, and to prey upon the weaker animals. These he places in a sub-genus, including the Zerda (*Megalotis* of Illiger, *Canis Megalotis* of Lalande, *Canis Zerda* of Gmelin); at least he terms the Zerdas "espèces de renards," though he seems to consider them as a section, and notices them as the *Megalotis* of Illiger. The *Hyæna venatica* of Burchell, *Hyæna picta* of Temminck (Wild Dog of the Cape), terminates Cuvier's *Canidæ*, and he then passes on to the Civets (*Viverra*).

M. Lesson in his 'Manuel' begins the second section of the Digitigrades with the genus *Canis*, and he adopts the following subdivisions:—

1. Those genera which have the pupil of the eye round, including the Dogs properly so called, the Wolves, and the Jackals.

2. Those genera in which the pupil of the eye contracts vertically, the Foxes and the Zerdas.

3. The Dogs with Hyæna-like feet; the Hyæna-Dog, *Canis pictus*, Desm., *Hyæna picta*, Temm., *Lycaon*, Brookes.

The genus *Canis* being mostly restricted at the present day to the animals of Lesson's first section, this article will be confined to the animals commonly called Dogs, Wolves, and Jackals.

Dogs.

C. familiaris, the Dog. The specific description given by Linnæus is simply "Canis caudâ (sinistrorsum) recurvatâ"—"dog with tail curled towards the left"—and his lengthened description, after enumerating the varieties, of which he gives eleven, though it may appear to some almost ridiculously minute and not very delicate, is eminently characteristic. Cuvier observes that the Domestic Dog (*Canis familiaris*, Linn.), is distinguished by its recurved tail, and that it varies infinitely besides in stature, form, colour, and the quality of the hair. It exhibits, he adds, "the most singular, the most complete, and the most useful conquest that man has made. The whole species is become our property; each individual is entirely devoted to his master, adopts his manners, distinguishes and defends his property, and remains attached to him even unto death; and all this springs not from mere necessity, nor from constraint, but simply from reconnaissance and a true friendship. The swiftness, the strength, and the highly developed power of smelling of the dog, have made him a powerful ally of man against the other animals, and were perhaps necessary to the establishment of society. It is the only animal that has followed man all over the earth."

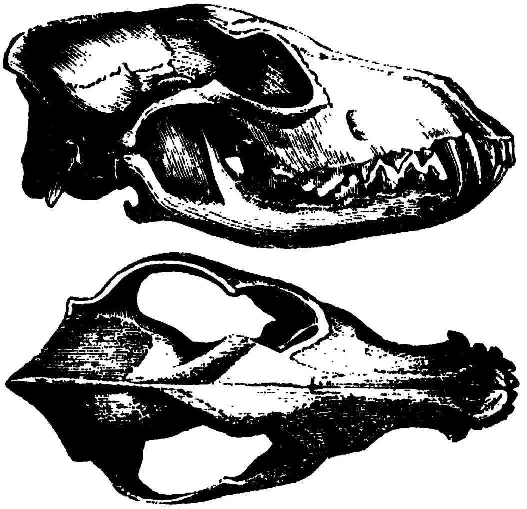
It is a question of considerable interest as to what was the parent-stock of the Dog. Some zoologists are of opinion that the breed is derived from the Wolf; others that it is a familiarised Jackal; all agree that no trace of it is to be found in a primitive state of nature. That there were dogs or rather animals of the canine form in Europe long ago we have evidence from their remains, which we shall presently notice; and that there are wild dogs we know. India, for example, affords many of them, living in a state of complete independence, and without any indication of a wish to approach the dwellings of man. These dogs, though they have been accurately noticed by competent observers, do not throw much light on the question. They may have escaped from the dominion or half dominion of man, and have betaken themselves to a vagabond life. It becomes necessary however to examine into the state of these dogs, some of which are entirely wild and keep to the mountain and forest, whilst others hang about the villages, and though without owners give tokens of a more social disposition, and are tolerated as the scavengers of the place, which they clear of disgusting incumbrances, somewhat after the Portuguese fashion.

Colonel Sykes thus describes the Dukhun (Deccan) Dog, *Canis Dukhunensis*, Sykes, Kolsun of the Mahrattas, *Cuon Dukhunensis*:—"Red, paler underneath; tail bushy, pendulous; pupil rounded. This is the Wild Dog of Dukhun. Its head is compressed and elongated; its nose not very sharp, the eyes are oblique: the pupils round, irides light brown. The expression of the countenance that of a coarse ill-natured Persian Grayhound, without any resemblance to the Jackal, the Fox, or the Wolf, and in consequence essentially distinct from the *Canis Quao* or *Sumatrensis* of General Hardwicke. Ears long, erect, somewhat rounded at the top, without any replication of the tragus. Limbs remarkably large and strong in relation to the bulk of the animal, its size being intermediate between the Wolf and the Jackal. Neck long. Body elongated. Between the eyes and nose red brown: end of the tail blackish. From the tip of the nose to the insertion of the tail 33 inches in length: tail 8½ inches. Height of the shoulders 16½ inches." Colonel Sykes adds that none of the domesticated dogs of Dukhun are common to Europe. The first in strength and size is the Brinjaree Dog, somewhat resembling the Persian Grayhound but much more powerful. The Pariah Dog he states is referrible to M. Cuvier's second section. This is very numerous, not individual property, but breeds in the towns and villages unmolested. The Colonel remarks that the Turnsprit Dog, long backed, with short crooked legs, is frequently found among the Pariahs. There is also a petted minute variety of the Pariah Dog, usually of a white colour, and with long silky hair, corresponding to a common Lapdog of Europe; this is taught to carry flambeaux and lanterns. The last variety noticed is the dog with hair so short as to appear naked like the *Canis Ægyptius*. It is known to Europeans by the name of the Polygar Dog. ('Zool. Proc.,' part i.) In 1832 the skin of the Wild Dog of Nepaul was compared by Colonel Sykes with a specimen of the Kolsun of the Mahrattas above described, and he stated his impression to be that the animals are identical, differing only by the denser coat and more woolly feet of the Nepaul race, a difference readily accounted for by the greater cold of the elevated regions inhabited by it. Colonel Sykes is also of opinion that the Kolsun is identical with the Buansuah, an Indian dog, described by Mr. B. H. Hodgson under the name of *Cuon primævus*. Specimens of these dogs are to be seen in the British Museum, in the Catalogue of which institution they are not only made specifically distinct, but are placed under the genus *Cuon* as distinct from *Canis*.

Mr. Bell, in his 'History of British Quadrupeds,' also discusses this difficult question. "In order," says Mr. Bell, "to come to any rational conclusion on this head, it will be necessary to ascertain to what type the animal approaches most nearly, after having for many successive generations existed in a wild state, removed from the influence of domestication and of association with mankind. Now we find that there are several different instances of the existence of dogs in such a state of wildness as to have lost even that common character of domestication, variety of colour and marking. Of these two very remarkable ones are the Dhole of India and the Dingo of Australia: there is besides a half-reclaimed race amongst the Indians of North America; and another also partially tamed in South America which deserve attention; and it is found that these races in different degrees, and in a greater degree as they are more wild, exhibit the lank and gaunt form, the lengthened limbs, the long and slender muzzle, and the great comparative strength which characterise the wolf; and that the tail of the Australian dog, which may be considered as the most remote from a state of domestication, assumes the slightly bushy form of that animal. We have here then a considerable approximation to a well-known wild animal of the same genus, in races which, though doubtless descended from domesticated ancestors, have gradually assumed the wild condition; and it is worthy of especial remark, that the anatomy of the wolf, and its osteology in particular, does not differ from that of the dogs in general, more than the different kinds of dogs do from each other. The cranium is absolutely similar, and so are all or nearly all the other essential parts; and to strengthen still further the probability of their identity, the dog and wolf will readily breed together, and their progeny is fertile. The obliquity of the position of the eyes in the wolf is one of the characters in which it differs from the dogs; and although it is very desirable not to rest too much upon the effects of habit on structure, it is not perhaps straining the point to attribute the forward direction of the eyes in the dogs to the constant habit, for many successive generations, of looking forwards to their master and obeying his voice."

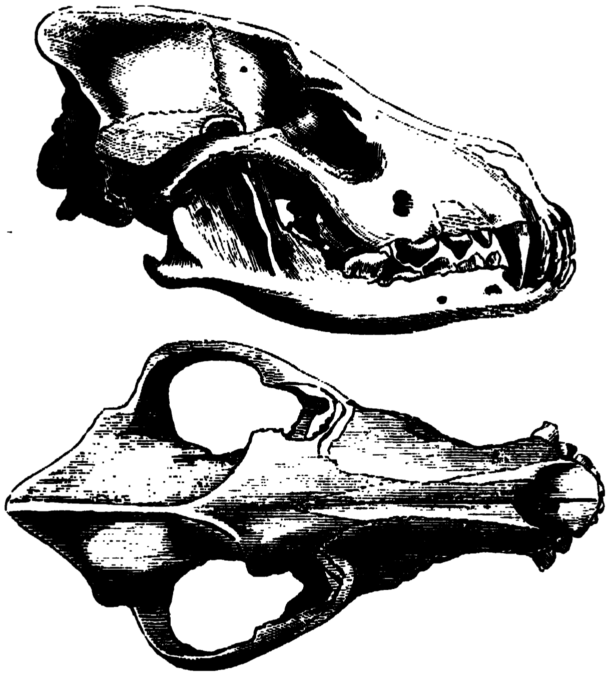
Another criterion, and a sound one, is the identity of gestation. Sixty-three days form the period during which the bitch goes with young. Precisely the same time elapses before the she-wolf gives birth to her offspring. Upon Buffon's instance of 73 days, or rather the possibility of such a duration in the gestation of a particular she-wolf, we do not lay much stress when opposed by such strong evidence of the usual period being 63 days. The young of both wolf and dog are born blind, and see at the same or about the same time, namely, at the expiration of the 10th or 12th day.

Hunter's important experiments proved without doubt that the Wolf and the Jackal would breed with the Dog; but he had not sufficient data for coming to the conclusion that all three were identical as species. In the course of those experiments he ascertained that the jackal went 59 days with young, whilst the wolf went 63 days; nor does he record that the progeny of the dog and jackal would breed together: and he knew too well the value of the argument to be drawn from a fertile progeny not to have dwelt upon the fact if he had proved it; not to have mentioned it, at least, if he had ever heard of it.

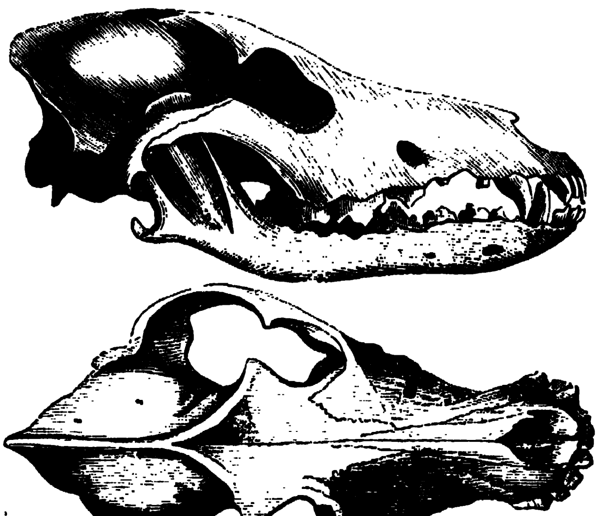


Skull of Jackal (*Canis aureus*). From F. Cuvier.

Mr. Bell disposes of the objection arising from the alleged untameably savage disposition of the wolf by relating two anecdotes, one on his own authority and the other on that of Mons. F. Cuvier, in proof of the susceptibility of attachment to man, and the appetite—for it is an appetite—for his caresses on the part of the wolf. The first occurred in the Gardens of the Zoological Society in the Regent's Park, London, and was exhibited in the person of a she-wolf, who came forward to be caressed, and even brought her pups to be caressed also, whenever Mr. Bell or any one whom she knew approached her den. Indeed she killed all her unfortunate young ones in succession by rubbing them against the bars of her cage in her zeal to have them fondled by her friends. The second happened in the Ménagerie du Roi at Paris, and no faithful dog could show more affecting instances of attachment to his master, or distress on account of his absence, than did the male wolf which is the subject of Mons. F. Cuvier's touching account. "With all these analogous properties of form and structure"—we quote Mr. Bell—"as well as of disposition, I cannot but incline at least to the opinion that the wolf is the original source from which all our domestic dogs have sprung: nor do I see in the great variety which exists in the different races sufficient ground for concluding that they may not, all of them, have descended from one common stock. The turnspit and the mastiff, the pug and the grayhound, are perhaps more unlike each other than any of the varieties of other domestic animals; but if it be true that variation depends upon habit and education, the very different employments to which dogs have in all ages been trained, and the various climates to which they have been naturalised, must not be lost sight of as collateral agents in producing these different forms. The care too with which dogs of particular breeds are matched with similar ones, for the purpose of keeping the progeny as pure as possible, has doubtless its effect in promoting such distinctions." The same author thus sums up his opinion:—"Upon the whole, the argument in favour of the view which I have taken, that the wolf is probably the original of all the canine races, may be thus stated: the structure of the animal is identical, or so nearly so as to afford the strongest à priori evidence in its favour. The dog must have been derived from an animal susceptible of the highest degree of domestication, and capable of great affection for mankind; which has been abundantly proved of the wolf. Dogs having returned to a wild state, and continued in that condition through many generations, exhibit characters which approximate more and more to those of the wolf, in proportion as the influence of domestication ceases to act. The two animals will breed together, and produce fertile young. The period of gestation is the same."



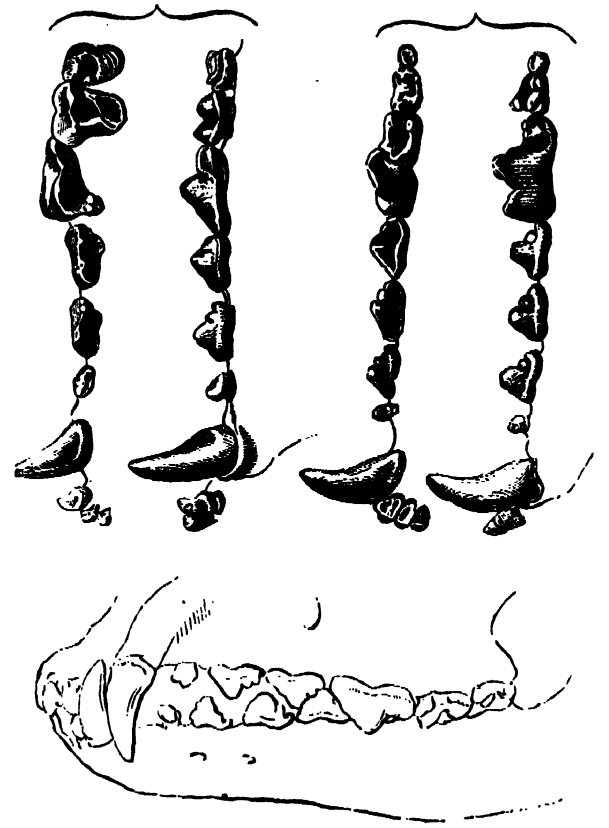
Skull of Wolf (*Canis Lupus*). From F. Cuvier.



Skull of Canada Wolf (*Canis Lupus*). From F. Cuvier.

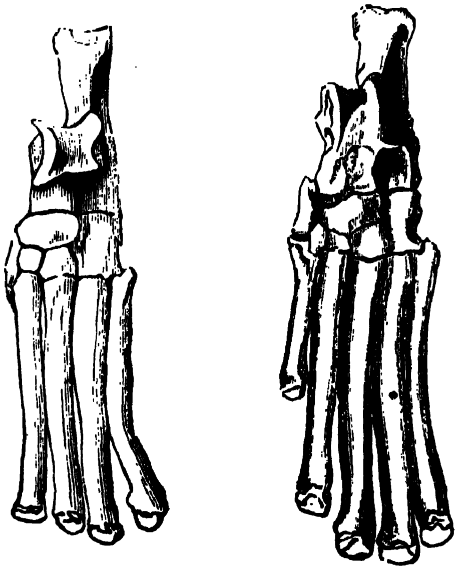
We have given above the skull of a wolf, that it may be compared with those of the different varieties of dogs.

Dental formula: incisors, $\frac{6}{6}$; canines, $\frac{1-1}{1-1}$; molars, $\frac{6-6}{7-7}$ = 42. Such is M. Lesson's statement of the dentition of the great genus *Canis* of Linnæus. F. Cuvier says that Dogs in general have 40 teeth, namely, six incisors, two canines, three false molars, one carnassier, and two tubercular teeth in the upper jaw; and six incisors, two canines, three false molars, one carnassier, and two tubercular teeth in the lower jaw. Of all these teeth, he observes, none change their shape in any appreciable degree in any race whatever. Only there is sometimes found an additional false molar or tubercular tooth.



Teeth of Dog.

Fore feet with five toes; hind feet with four toes; claws not retractile.

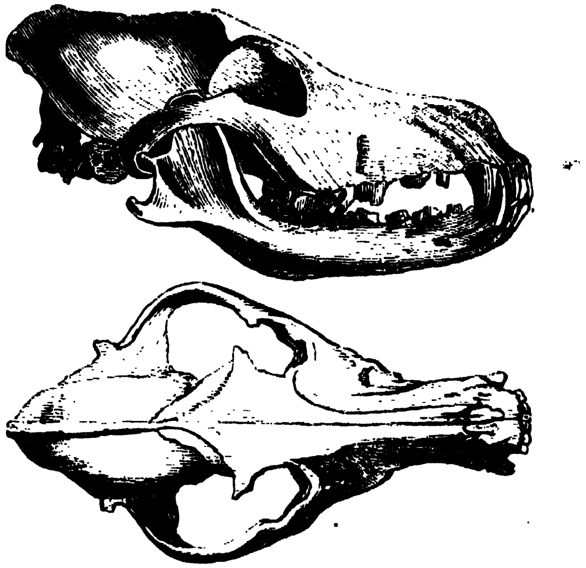


Feet of Dog. From F. Cuvier.

Generally speaking all dogs have five toes on the fore feet and four on the hind feet, with the rudiment of a fifth metatarsal bone, which does not show itself externally. Nevertheless some dogs have this fifth toe very long and well proportioned, and advancing as far as the origin of the first phalanx of the neighbouring toe; and in those dogs which have only a rudimentary fifth bone of the tarsus, this bone articulates itself to the lower facet of the great cuneiform bone, which is itself placed in relation with the scaphoïd bone, the second cuneiform bone, and the second bone of the metatarsus, counting as one the rudiment in question. But in the dogs that have the fifth toe complete, a fourth cuneiform bone is developed between the first and the second toe, and in that case, in some varieties, the great cuneiform bone elevates itself, and on its internal side offers a large articulating facet to the astragalus.

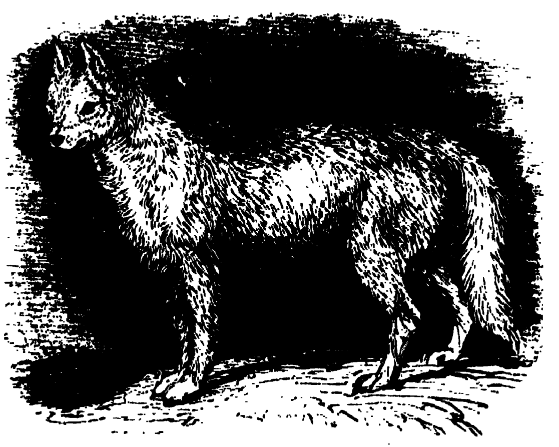
The tail is very variable in the number of caudal vertebræ, which range from twenty-one down to three or even two.

Of dogs which have been regarded as varieties or species, one of the most remarkable is the Australian Dog, or Dingo (*Canis Dingo* of Blumenbach). It is so wolf-like in its appearance, that Bewick figures it as the 'New-South-Wales Wolf.' Governor Philip describes the height of this species, when standing erect, as rather less than 2 feet, and the length 2½ feet. The head, he says, is formed much like that of a fox, the ears short and erect, with whiskers from 1 to 2 inches in length on the muzzle. The general colour of the upper parts is pale brown, growing lighter towards the belly; the hind part of the fore legs and the fore part of the hinder ones white, as are the feet of both; the tail is of a moderate length, somewhat bushy, but in a less degree than that of a fox: the teeth, he adds, are much the same as is usual in the genus.



Skull of Dingo (*Canis Dingo*). From F. Cuvier.

This description may be considered as accurate, with the exception that the animal generally bears a greater affinity to the Wolf than the Fox. "It has," says the author last quoted, describing a female, "much of the manners of the dog, but is of a very savage nature, and not likely to change in this particular. It laps like other dogs, but neither barks nor growls if vexed and teazed; instead of which it erects the hairs of the whole body like bristles, and seems furious: it is very eager after its prey, and is fond of rabbits or chickens raw, but will not touch dressed meat. From its fierceness and agility it has greatly the advantage of other animals much superior in size; for a very fine French fox-dog being put to it, in a moment it seized him by the loins, and would have soon put an end to his existence had not help been at hand. With the utmost ease it is able to leap over the back of an ass, and was very near worrying one to death, having fastened on it so that the creature was not able to disengage himself



Dingo (*Canis familiaris Australasiæ*, or *C. Dingo*).

without assistance: it has also been known to run down both deer and sheep. A second of these is in the possession of Mr. Lascelles, of which we have received much the same account in respect of its ferocity; whence it is scarcely to be expected that this elegant animal will ever become familiar."

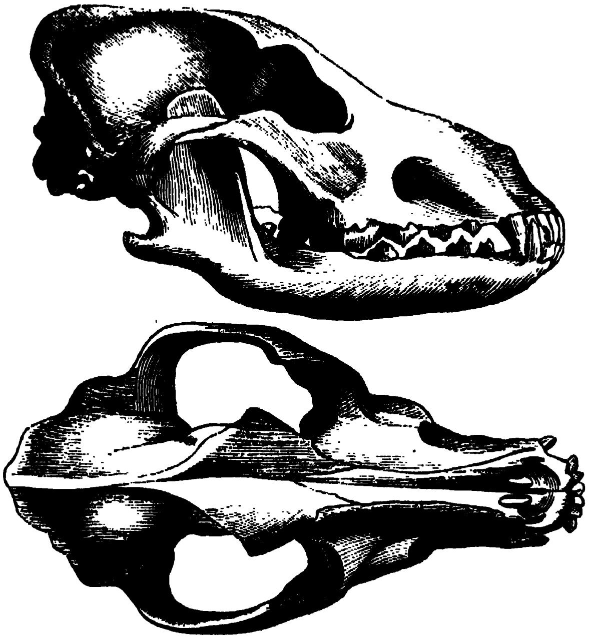
Mr. Bell, in his work above quoted, describes the first effect of the dominion of man upon this wolf-like dog:—"The effect of domestication in producing variation in colour, to which allusion has already been made, has lately been exhibited in a very striking and interesting manner in the menagerie of the Zoological Society. An Australian bitch, or Dingo, had a litter of puppies, the father of which was also of that breed: both of them had been taken in the wild state, but were of the uniform reddish brown colour which belongs to the race, and the mother had never bred before; but the young, bred in confinement and in a half-domesticated state, were all of them more or less spotted."

If we turn to the dogs of other comparatively uncivilised nations, we find the prick ears and other indications of the half-reclaimed animal. The Esquimaux Dog (*Canis familiaris Borealis*), and the Hare-Indian or Mackenzie River Dog (*Canis familiaris Lagopus*), will occur as instances to those who have been familiar—and who is not?—with the histories of our northern expeditions and the Garden of the Zoological Society of London in the Regent's Park. In that menagerie the three dogs last named might at one time be seen side by side, affording the best opportunities for comparison. Peter, the Esquimaux Dog, kept in the garden, was of a dingy-white with a tinge of yellow on the upper parts, gradually fading away upon the sides; in short, of nearly a uniform colour; but in general this race exhibits a predominance of black markings. Thus Akshelli, brought from the Polar Sea by Mr. Richards in Captain Parry's first voyage, and described by Mr. Children in the 'Zoological Journal,' was almost entirely blackish, or of a colour nearly approaching to black on the upper parts, and white underneath, tail included. Akshelli seldom barked, but if displeased uttered a low wolfish growl, and was a very powerful dog. Peter was brought to this country by Lieutenant Henderson, one of the companions of Captain Ross, in his first voyage, and lived long at the Regent's Park. He was very good tempered and familiar. The Hare-Indian Dogs, it is said, are never known to bark in their own country; and it is worthy of note that those which were brought from thence to the Regent's Park never barked at all, but the younger one which was born here barked like the other dogs. It is curious to observe these steps.

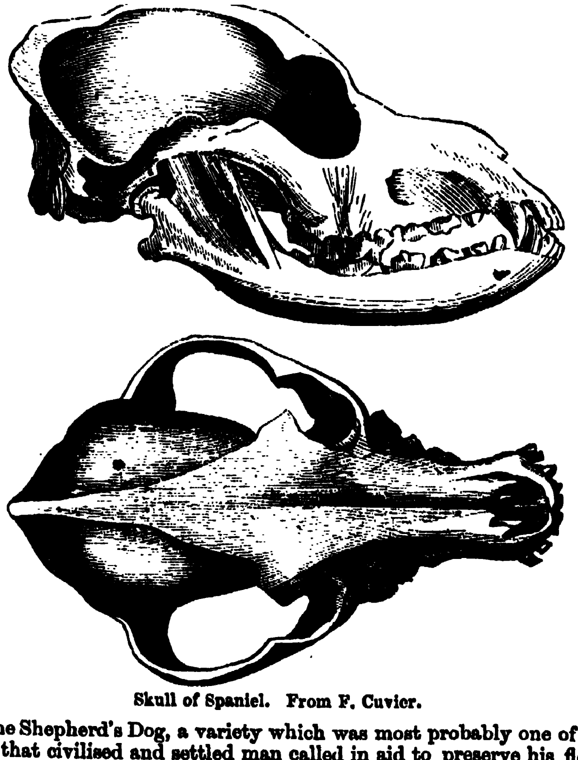
"The period," says Mr. Bell, "at which the domestication of the dog first took place is wholly lost in the mist of antiquity. The earliest mention of it in the Sacred Scriptures occurs during the sojourn of the Israelites in Egypt—'But against Israel shall not a dog move his tongue.' It is again mentioned in the Mosaic law in a manner which would seem to show that they were the common scavengers of the Israelitish camp, as they are still in many of the cities of the East:—'Neither shall ye eat any flesh that is torn of beasts in the field: ye shall cast it to the dogs.' A similar office seems to be repeatedly alluded to in the course of the Jewish history:—'Him that dieth in the city shall the dogs eat, and him that dieth in the fields shall the fowls of the air eat;' a common curse, as it would appear, as it occurs verbatim on no less than three separate occasions in the First Book of Kings; and evidently intimates a violent and disgraceful death, without the honour of sepulture. The dog was considered by the Jews as eminently an unclean animal, and was the figure selected for the most contemptuous insults. It is impossible not to be struck with the striking similarity which exists in the feelings of many oriental nations at the present day, among whom the very phraseology of the Scriptures is, with little modification, applied to a similar purpose."

Asiatic Street-Dogs.

One circumstance should be borne in mind throughout an inquiry into the origin of the Dog. None of the wild dogs, however apparently living in a state of nature, have ever been found to return to the true form of Wolf.



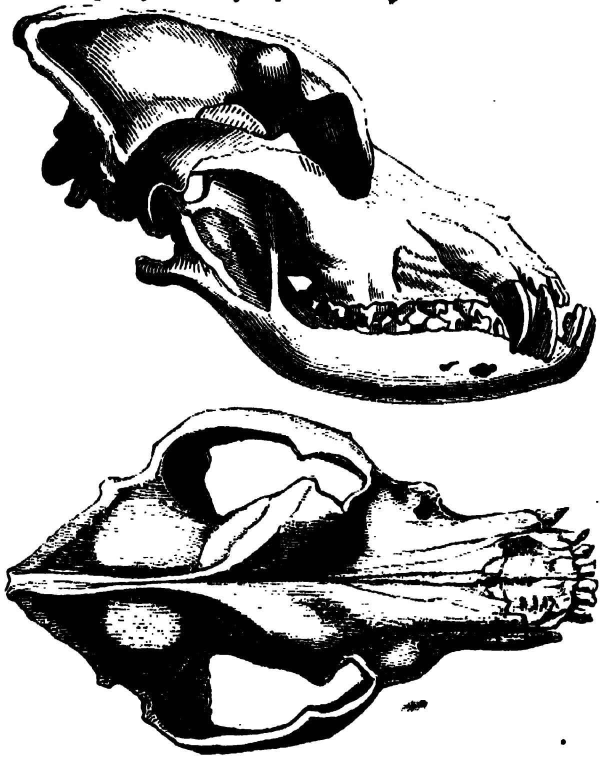
Skull of Shepherd's Dog (Chien de Berger). From F. Cuvier.



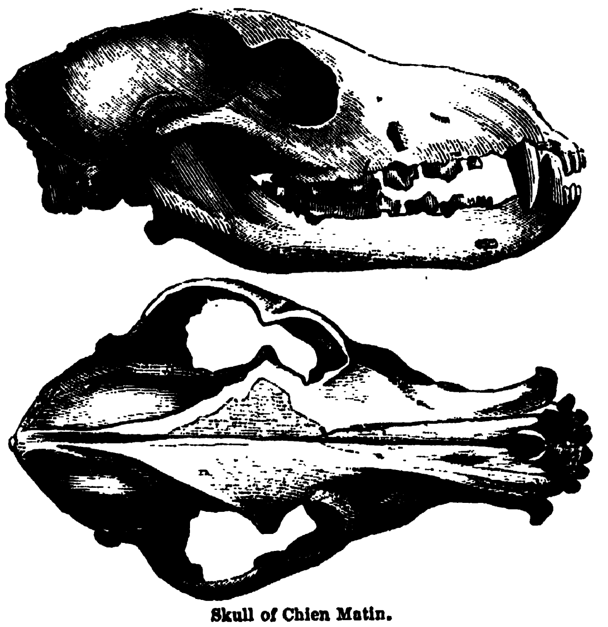
Skull of Spaniel. From F. Cuvier.

The Shepherd's Dog, a variety which was most probably one of the first that civilised and settled man called in aid to preserve his flocks from beasts and birds of prey and the depredations of roving human tribes, is remarkable for the capacity of its cranium and its great sagacity.

It is indeed distinguished by this cranial development even above the Spaniels and their varieties, and the Hounds, which comprise the most useful and intelligent dogs. In the Bull-Dogs and Mastiffs, Dogues de Forte Race of the French, though the head is one-third larger than those of the Shepherd's Dog and of the Spaniels, 'Barbets,' the cranial capacity is not by any means so great.



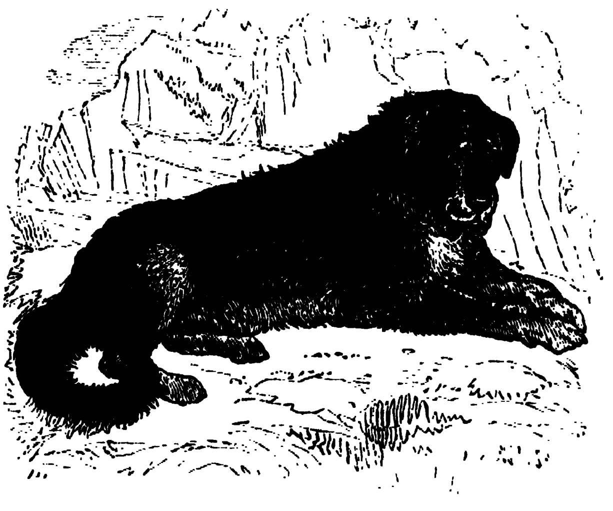
Skull of Dogue de Forte Race. From F. Cuvier.



Skull of Chien Matin.

Dr. Caius, the physician of queen Elizabeth's time, wrote several papers on natural history for the use of Gesner, his correspondent and friend. In one of these treatises he divides the British dogs into —1st, The most generous kinds, which he subdivides into the Dogs of Chace, including the Hounds, namely, the Terrier, Harrier, and Bloodhound; and the Gazehound, Grayhound, Leviner or Lyemmer, and Tumbler: the Fowlers, namely, the Spaniel, Setter, Water-Spaniel, or Finder: and the Lap-Dogs, namely, the Spaniel-Gentle, or Comforter. 2nd, The Farm-Dogs, namely, the Shepherd's Dog and the Mastiff, or Ban-Dog. 3rd, Mongrels, namely, Wappe, Turnspit, and Dancer.

Bewick enumerates the following:—The Shepherd's Dog, the Cur-Dog, the Greenland-Dog, the Bull-Dog, the Mastiff, the Ban-Dog, the Dalmatian or Coach-Dog, the Irish Grayhound, the Highland Grayhound, the Gazehound, the Grayhound, the Italian Grayhound, the Lyemmer, the Lurcher, the Tumbler, the Terrier, the Beagle, the Harrier, the Fox-Hound, the Old English Hound, the Kibble Hound, the Blood-Hound, the Spanish Pointer, the English Setter, the Newfoundland Dog, the Rough Water-Dog, the Large Water-Spaniel, the Small Water-Spaniel, the Springer or Cocker, King Charles's Dog, the Pyrame Dog, the Shock-Dog, the Lion-Dog (a small and rare variety), the Comforter (a small Spaniel), the Turnspit, and the Pug. We could add many more to this list, which is long enough. The French divide the dogs into three groups, namely, the Mâtins, the Spaniels (including the Hounds and Pointer), and the Dogues (the last containing the Mastiff, Bull-Dog, &c.).



The Tibet Dog (*Canis familiaris*, var. *Molossus Thibetanus*).

We give the gigantic Tibet Dog as a fine example of the Mastiffs. Dr. Wallich gave to Mr. Broderip the data which enabled the latter to write the following account:—"These noble animals are the watch-dogs of the table-land of the Himalaya Mountains, about Tibet. Their masters, the Bhoteas, to whom they are most strongly attached, are a singular race, of a ruddy copper-colour, indicating the bracing air which they breathe, rather short, but of an excellent dispostion. Their clothing is adapted to the cold climate they inhabit, and consists of fur and woollen cloth. The men till the ground and keep sheep, and at certain seasons come down to trade, bringing borax, tincal, and musk, for sale. They sometimes penetrate as far as Calcutta. On these occasions the women remain at home with the dogs, and the encampment is watched by the latter, which have an almost irreconcileable aversion to Europeans, and in general fly ferociously at a white face. A warmer climate relaxes all their energies, and they dwindle even in the valley of Nepaul." Some specimens were brought to this country by Dr. Wallich; they were placed in the Zoological Society's Garden in the Regent's Park, but died soon after their arrival. The Hon. Edward Gardner, British resident at the court of the Raja of Nepaul, never heard of any other instance of this variety being domesticated by Europeans.

In all the varieties the period of gestation is 63 days. The litter is generally numerous, often as many as eight or nine. The whelps are born blind, and do not see till nine days are fully expired: they sometimes see on the tenth, and sometimes not till the twelfth day. At the fourth month the teeth begin to change, and at two years the growth of the animal is considered complete. A dog is considered old at the expiration of five years, and the limits of his existence rarely exceed 20 years. It is confidently stated that in all the varieties, if a Dog has any white on any part of his tail, that colour will invariably be found at the tip.

For the special qualities of particular varieties of the Dog see the articles Beagle, Blood-Hound, Grayhound, Harrier, Pointer, Pug, Setter, Spaniel, Terrier, Wolf-Dog.

Wolves.

C. Lupus (Linnæus), the Wolf. Lieutenant-Colonel Hamilton Smith makes *Lupus* the first section of his first sub-genus *Chaon*, of the Diurnal *Canidæ*, or Canine group furnished with a round pupil of the eye.

In this section he comprises the Common Wolf, *Lupus vulgaris;* the Black Wolf, *L. Lycaon;* the Dusky Wolf, *L..nubilus*, Wied.; and the Wolf of the Southern States of North America, *L. Mexicanus*, Smith.

In the second section, *Lyciscus*, or as he terms the group the Lyciscan Dogs, he places the North American Wolf, *L. latrans;* and the Caygotte of Mexico, *L. Cagottus*, Smith.

With regard to the American Wolves, Colonel Smith remarks that whether they be distinct from those of the eastern hemisphere, or primeval varieties, is not as yet satisfactorily established. The high authority of Sir John Richardson he observes leans towards the opinion that they are different species; while Prince Maximilian of Wied, perhaps still more practically conversant with the races of both continents, thinks that they are not specifically distinct. To this last-mentioned opinion Colonel Smith states that his own somewhat extensive researches lead him to subscribe; but he qualifies this statement by observing that while our ideas respecting the characteristics of species remain unsettled the difference of conclusion is perhaps only formular.

In M. Lesson's 'Manuel' the following existing Wolves appear as distinct species:—the Common Wolf, *C. Lupus*, Linn.; the Mexican Wolf, *C. Mexicanus*, Desm.; the Red Wolf, *C. jubatus*, Desm.; the Prairie Wolf, *C. latrans*, Harl.; and the Dusky Wolf, Loup Odorant, *C. nubilus*, Say.

Colonel Smith observes that the typical Wolf of Europe and Asia, and the varieties belonging to this tribe in America, may be described as animals occupying the two continents from within the Arctic circle on the north, to Spain, and perhaps to Marocco on the west side of the Old Continent; to Syria, and beyond the Crishna in India; and to near the Isthmus of Panama in the New World. Farther south, in the last-mentioned part of the globe, they are, he remarks, replaced by an aberrant canine, the Red Wolf of Cuvier; and in the first by Hyænas, the Painted Lycaon (*Canis pictus*), and perhaps by other species not as yet fully developed. "In China," says Colonel Smith, "wolves abound in the province of Xantung [Changtung?]; but how far they are found to the south is not known. Buffon, from the account of Adançon (Adanson), asserts the existence of a powerful race of wolves in the Senegal country, hunting in company with the lion; but the name is most likely applied to a hyæna, a lycaon, or one of the red chrysean group." ('Naturalist's Library.')

The following must be the passage alluded to:—Adanson states that one night a lion and a wolf (loup) entered together in the court of the house where he slept; they raised themselves by turns by placing their feet on the timber-work of the roof (comble), as he could easily hear, and carried off their provision. In the morning the occupiers of the dwelling were satisfied, from the well-marked impressions of their feet in the sand, that the animals came together, and perceived the place whence they had taken away two fish: doubtless, says Adanson, each took his own. This theft, he adds, was moderate for two such carnivorous animals, but they did not choose the smallest. "I do not know," continues the French traveller, "that it has been before observed that the wolf goes (fraye) with the lion; nevertheless the fact is not extraordinary; there are daily proofs of it in this country, and every evening the wolf may be heard howling at the side of the lion. I have witnessed the same thing a hundred times in all my voyages on the Niger (the Senegal), and I know, without possibility of doubt, that the wolf is often found with the lion without having anything to fear. It is not that the size of the African wolf, which is much superior to that of the wolf of Europe, makes any impression on the lion; it is only because the flesh of the former is no temptation to the latter: and what confirms me in this opinion is, that I never saw the two lions which were kept in the middle of the village of Senegal attack the dogs which were exposed to them, or which they met when they were unchained; whereas they fell upon the first horse or child which came in their way."

Le Vaillant and the French generally called the Spotted Hyæna Loup Tacheté; and the terms Tigre and Tigresse are used generally for any large spotted cat. Thus we have an account of the 'Hardiesse du Tigre' in Adanson's very next sentence, where he says—"Some days after this visit of the lion with the wolf we received one from a tigress, which came to the same place with her young one and also carried away two fish." In the 'New History of Ethiopia, being a Full and Accurate Description of the Kingdom of Abessinia, vulgarly, though erroneously, called the Empire of Prester John; in four books: by the learned Job Ludolphus, Author of the Ethiopic Lexicon; made English by J. P. Gent. Folio, London, 1682,'—is the following passage:—"Tygers and panthers are much more cruel and fierce than lyons, for they never spare mankind; yet they covet the Ethiopians before white men, as more accustomed to that sort of dyet. These two beasts differ only in colour; for the panthers are brown, spotted with black; the tigers gold-coloured, with fine black spots like five-leaved grass: they are beasts of a dreadful celerity and boldness; by night they break into villages, and make doleful massacres among the poor innocent cattle; yet Alvarez affirms that these butcheries never happen in Midra-Bahrà." It is almost superfluous to add, that the Tiger, properly so called, does not inhabit Africa.

C. Lupus, the Common Wolf, is known by the following characters:—It is yellowish or fulvous gray; hair harsh and strong, longest below the ears and on the neck (particularly the throat), shoulders, and haunches; muzzle black; cheeks and parts above the eyes ochreous, gray in very old subjects; upper lip and chin white; eyes oblique; tail not curling; a blackish streak or band on the fore legs about the carpus; height at the shoulder from 27 to 29 inches.

Variety white: either as an albino, or according to the French writers, from the effect of the northern climate in the winter. Colonel Smith is of opinion that the white wolves occurring sometimes among the races of middle Europe are mere cases of albinism.

This is the wolf that more commonly infests the western countries of Europe. Cuvier state that it is found from Egypt to Lapland, and seems to have passed over into America. Colonel Smith remarks that the French wolves are generally browner and somewhat smaller than those of Germany; that the Russian race is longer, and appears more bulky and formidable from the great quantity of long coarse hair on the cheeks, gullet, and neck; their eyes are very small, and their whole aspect peculiarly savage and sinister; that the Swedish and Norwegian wolves are similar to the Russian in form, but appear heavier and deeper in the shoulder, lighter in colour than the Russian race, and in winter totally white; that the Alpine wolves are brownish-gray and smaller than the French; those of Italy and to the eastward towards Turkey fulvous.

This is the variety, most probably, which formerly lurked in the uncleared woody districts of the British Islands; for that Wolves were once numerous here is as clear as that the Bear once prowled in Scotland and Wales. It would be a waste of paper and space to detail the documentary evidence, and that to be derived from ancient coins, gems, and sculptures, which prove that the *Lupus* of the Roman historians and poets, and the *Lupa* which was fabled to have suckled Romulus and Remus was the same animal with the ancient British Wolf. Whatever the Romans might have done to put down these ferocious but cowardly beasts of prey, they left enough for their Saxon and Norman successors to do. Edgar applied himself to their extirpation in earnest, enlisting English criminals in the service by commuting the punishment awarded for their crimes to a delivery of a given number of wolves' tongues, and liberating the Welsh from the payment of the tax of gold and silver on condition of an annual tribute of 300 wolves. But the vast wild tracts and deep forests of ancient Britain were holds too strong even for his vigorous measures. What the numbers and consequent danger had been may be imagined from the necessity that existed in the previous reign of Athelstane (A.D. 925) for a refuge against their attacks. Accordingly a retreat was built at Flixton in Yorkshire, to save travellers from being devoured by these gaunt hunters. The Saxon name for the month of January, Wolf-Monath, in which dreary season hunger probably made the wolves most desperate, and the term for an outlaw, 'Wolf's-Hed,' implying that he might be killed with as much impunity as a wolf, also indicate the numbers of these destructive beasts, and the hatred and terror which they inspired.

That Edgar failed in his attempts at extirpation is manifest from a mandamus of Edward I. to all bailiffs, &c. to give their assistance to his faithful and beloved Peter Corbet, whom the king had enjoined to take and destroy wolves (lupos), "cum hominibus, canibus, et ingeniis suis modis omnibus quibus viderit expedire," in all forests and parks and other places in the counties of Gloucester, Worcester, Hereford, and Salop, where they could be found. King John, in his grant, quoted by Pennant from Bishop Lyttelton's collection, as being in the possession of the dean and chapter of Exeter, mentions the wolf (lupum) among the beasts of chace which the Devonshire men are thereby licensed to kill.

In Derbyshire certain tenants at Wormhill held their lands by the duty of hunting and taking the wolves ('Wolve Hunt') which harboured in the county. Even so late as 1577 the flocks of Scotland appear to have suffered from the ravages of wolves, which do not seem to have been rooted out of that portion of the kingdom till about the year 1680, when Sir Ewen Cameron's hand laid the last wolf low. In Ireland wolves must have lingered as late as the year 1710, about which time the last presentment for killing them in the county of Cork was made.

The Black Wolf is a name given to a variety which is most frequent in Southern Europe, and particularly in the Pyrenees and to the south of those mountains, where they are more common than the ordinary or last-mentioned wolf, which the Black Wolf equals in stature, and, if anything, exceeds in strength. Cuvier says that it is found, but very rarely, in France. Colonel Hamilton Smith relates an anecdote illustrative of its great size and weight. One of these wolves at a battue in the mountains near Madrid came bounding towards an English gentleman who was present at the sport, through the high grass and bushes, so large that the sportsman took it for a donkey. Seven were slain; and this gentleman, though active and in the flower of life, could not lift one entirely from the ground. The specimen figured by the Colonel came from the banks of the Tagus, and he describes it as equal to the largest mastiff, of a very dark brown colour, with ears larger and the muzzle thicker than the Common Wolf, but withal resembling a very large and shaggy Wolf-Dog.

"The Spanish Wolves," says Colonel Smith, "congregated formerly in the passes of the Pyrenees in large troops, and even now the Lobo will accompany strings of mules as soon as it becomes dusky. They are seen bounding from bush to bush by the side of travellers, and keeping parallel with them as they proceed, waiting an opportunity to select a victim; and often succeeding unless the muleteers can reach some place of safety before dark, and have no dangerous passes to traverse. Black wolves occur again in the mountains of Friuli and about Cattaro."

The Vekvoturian Mountain-Wolf of Russia, described by Pallas, belongs to the black variety. Colonel Smith thinks that the Rossomak of the Lenas in Siberia, with shining black valuable fur, is probably the same.

The female of the Common Wolf produces four or five at a litter;

and although it is said that until the young can see, the female carefully hides them from the male, for fear he should devour them, it is certain that he hunts for them and brings them food, consisting for the most part of the smaller quadrupeds, partridges, moor-game, &c., after they have the use of their eyes, and that both parents take their offspring out to teach them to hunt as soon as they are strong enough.

The Common Wolf (*Canis Lupus*).

Several varieties or species of Wolf are met with in Asia. The Landgah, or Indian Wolf, is the *Canis pallipes* of Sykes, and the *Saccalius Indicus* of Hodgson. It is an inhabitant of Nepaul.

The wolves of Asia Minor are fulvous, but the colour is more predominant and has more red in it than that of the Italian wolves.

Of the Indian wolves, one, the Beriah, is described as being of a light fox-colour inclining to dun, not larger than a grayhound, slenderly made, but bony; the head and ears long, like those of a Jackal, and the tail long, but not very hairy; the other, which is smaller, Colonel Smith refers to his Lyciscan group. The last-named zoologist refers the black Derboun of the mountains of Arabia and the south of Syria to the Wolf.

The wolf, or the lupine forms of the genus *Canis*, are found in America. Sir John Richardson, in the 'Fauna Boreali-Americana,' observes that the Common Wolves of the Old and New World have been generally supposed to be the same species—the *Canis Lupus* of Linnaeus. The American naturalists have indeed, he remarks, described some of the northern kinds of wolf as distinct; but it never seems to have been doubted that a wolf possessing all the characters of the European Wolf exists within the limits of the United States. He then goes on to point out that the wolf to which these characters have been ascribed seems to be the Large Brown Wolf of Lewis and Clark; and, according to them, it inhabits not only the Atlantic countries, but also the borders of the Pacific and the mountains which approach the Columbia River, between the great falls and rapids, but is not found on the Missouri to the westward of the Platte. Richardson remarks that he had seen none of these Brown Wolves.

In the 'New Description of Virginia' (1649) wolves are mentioned among the beasts found there; and Lawson notices the Wolf of Carolina and thus describes him:—"The Wolf of Carolina is the dog of the woods. The Indians had no other curs before the Christians came amongst them. They are made domestic. When wild they are neither so large nor fierce as the European Wolf. They are not man-slayers, neither is any creature in Carolina unless wounded. They go in great droves in the night to hunt deer, which they do as well as the best pack of hounds: nay, one of these will hunt down a deer. They are often so poor that they can hardly run. When they catch no prey they go to a swamp, and fill their belly full of mud; if afterwards they chance to get anything of flesh, they will disgorge the mud and eat the other. When they hunt in the night, and there is a great many together, they make the most hideous and frightful noise that ever was heard. The fur makes good muffs. The skin, dressed to a parchment, makes the best drum-heads, and if tanned makes the best sort of shoes for the summer-countries."

Catesby says:—"The wolves in America are like those of Europe in shape and colour, but are somewhat smaller. They are more timorous, and not so voracious as those of Europe. A drove of them will fly from a single man, yet in very severe weather there have been some instances to the contrary. Wolves were domestic with the Indians, who had no other dogs before those of Europe were introduced, since which the breed of wolves and European dogs are mixed and become prolific. It is remarkable that the European dogs that have no mixture of wolfish blood have an antipathy to those that have, and worry them whenever they meet. The wolf-breed act only defensively, and, with his tail between his legs, endeavours to evade the other's fury. The wolves in Carolina are very numerous, and more destructive than any other animal. They go in droves by night, and hunt deer like hounds, with dismal yelling cries."

Sir John Richardson gives a minute description of the *Canis Lupus occidentalis*, American Wolf, the Missouri Wolf of Lewis and Clark, and states that he does not mean to assert that the differences existing between it and its European congener are sufficiently permanent to constitute them, in the eye of the naturalist, distinct species. The same kind of differences, he observes, may be traced between the foxes and native races of the domestic dog of the New World and those of the Old; the former possessing finer, denser, and longer fur, and broader feet, well calculated for running on the snow. These remarks were elicited by a comparison of living specimens of American and Pyrenean wolves; but he had not an opportunity of ascertaining whether the Lapland and Siberian wolves, inhabiting a similar climate with those of America, had similar peculiarities of form, or whether they differed in physiognomy from the wolf of the south of Europe. He therefore considered it unadvisable to designate the northern wolf of America by a distinct specific appellation, lest he should unnecessarily add to the list of synonyms. The word *occidentalis*, which is affixed to the Linnæan name of *Canis Lupus*, is, he tells us, to be considered as merely marking the geographical position of that peculiar race of Wolf.

This animal is very common throughout the northern regions of America, but more or less abundant in different districts. "Their foot-marks," says Richardson, "may be seen by the side of every stream, and a traveller can rarely pass a night in these wilds without hearing them howling around him. They are very numerous on the sandy plains which, lying to the eastward of the Rocky Mountains, extend from the sources of the Peace and Saskatchewan rivers towards the Missouri. There bands of them hang on the skirts of the buffalo (bison) herds, and prey upon the sick and straggling calves. They do not, under ordinary circumstances, venture to attack the full-grown animal; for the hunters informed me that they often see wolves walking through a herd of bulls without exciting the least alarm; and the marksmen, when they crawl towards a buffalo for the purpose of shooting it, occasionally wear a cap with two ears, in imitation of the head of a wolf, knowing from experience that they will be suffered to approach nearer in that guise. On the Barren-Grounds through which the Coppermine River flows I had more than once an opportunity of seeing a single wolf in close pursuit of a rein-deer; and I witnessed a chace on Point Lake when covered with ice, which terminated in a fine buck rein-deer being overtaken by a large white wolf, and disabled by a bite in the flank. An Indian, who was concealed on the borders of the lake, ran in and cut the deer's throat with his knife, the wolf at once relinquished his prey and sneaked off. In the chase the poor deer urged its flight by great bounds, which for a time exceeded the speed of the wolf; but it stopped so frequently to gaze on its relentless enemy, that the latter, toiling on at a 'long gallop' with its tongue lolling out of its mouth, gradually came up. After each hasty look the poor deer redoubled its efforts to escape; but, either exhausted by fatigue or enervated by fear, it became, just before it was overtaken, scarcely able to keep its feet."

The same author observes that the wolves destroy many foxes, which they easily run down if they perceive them on a plain at any distance from their hiding-places; and he relates that in January 1827 a wolf was seen to catch an Arctic Fox within sight of Fort Franklin, and although immediately pursued by hunters on snow-shoes, it bore off its prey in its mouth without any apparent diminution of its speed. The same wolf, he adds, continued for some days to prowl in the vicinity of the fort, and even stole fish from a sledge which two dogs were accustomed to draw home from the nets without a driver. As this kind of depredation could not be allowed to go on, the wolf was waylaid and killed. It proved to be a female, which accounted for the sledge-dogs not having been molested. He further states that the buffalo-hunters would be unable to preserve the game they kill from the wolves if the latter were not as fearful as they are rapacious. The simple precaution of tying a handkerchief to a branch, or of blowing up a bladder and hanging it so as to wave in the wind, is sufficient to keep herds of wolves at a distance. At times, however, he says that they are impelled by hunger to be more venturous, and that they have been known to steal provisions from under a man's head in the night, and to come into a traveller's bivouac and carry off some of his dogs. "During our residence at Cumberland House in 1820," continues Sir John, "a wolf, which had been prowling round the fort, and was wounded by a musket-ball and driven off, returned after it became dark, whilst the blood was still flowing from its wound, and carried off a dog from amongst fifty others, that howled piteously, but had not courage to unite in an attack on their enemy. I was told of a poor Indian woman who was strangled by a wolf, while her husband, who saw the attack, was hastening to her assistance; but this was the only instance of their attacking human life that came to my knowledge. As the winter advances and the snow becomes deep, the wolves, being no longer able to hunt with success, suffer from hunger, and in severe seasons many die. In the spring of 1826 a large gray wolf was driven by hunger to prowl amongst the Indian huts which were erected in the immediate vicinity of Fort Franklin, but not being successful in picking up aught to eat, it was found a few days afterwards lying dead on the snow near the fort. Its extreme emaciation and the emptiness of its intestines showed clearly that it died from inanition."

We learn from the same excellent authority that the American Wolf burrows, and brings forth its young in earths with several outlets, like those of a fox. Sir John Richardson saw some of their burrows on the plains of the Saskatchewan, and also on the banks of the Coppermine River. The number in a litter he states to vary from four or five to eight or nine. After referring to the instances recorded in the narratives of Captain Parry and Captain Franklin of the association of the female wolves with the domestic dog, he relates that he was informed that the Indians endeavour to improve their sledge-dogs by crossing the breed with wolves, and he adds, that the resemblance between the northern wolves and the domestic dog of the Indians is so great, that the size and strength of the wolf seem to be the only difference. "I have more than once," says he, "mistaken a band of wolves for the dogs of a party of Indians; and the howl of the animals of both species is prolonged so exactly in the same key, that even the practised ear of an Indian fails at times to discriminate them."

Captain Lyon gives the following account of the Esquimaux wolf-trap. It is made of strong slabs of ice, long and narrow, so that a fox can with difficulty turn himself in it, but a wolf must actually remain in the position in which he is taken. The door is a heavy portcullis of ice, sliding in two well-secured grooves of the same substance, and is kept up by a line, which, passing over the top of the trap, is carried through a hole at the furthest extremity; to the end of the line is fastened a small hoop of whalebone, and to this any kind of flesh-bait is attached. From the slab which terminates the trap, a projection of ice, or a peg of wood or bone, points inwards near the bottom, and under this the hoop is lightly hooked; the slightest pull at the bait liberates it, the door falls in an instant, and the wolf is speared where he lies.

The following varieties of the North American Wolf are enumerated by Sir John Richardson:—

Variety *a*. Common Gray Wolf, *Lupus griseus*, the Mahaygan of the Cree Indians, and the Amarok of the Esquimaux.

Variety *b*. The White Wolf, *Lupus albus*.

Variety *c*. The Pied Wolf, *Lupus sticte*.

Variety *d*. The Dusky Wolf, *Lupus nubilus*, *Canis nubilus* of Say.

The Dusky Wolf (*Lupus nubilus*).

Variety *e*. The Black American Wolf, *Lupus ater*, *Canis Lycaon* of Harlan.

C. latrans (Say), the Prairie Wolf, *Lyciscus latrans* of Smith.

The animals which are thus distinguished have been long known to voyagers on the Missouri and Saskatchewan, as distinct from the Common Wolf. They are the Small Wolves of Du Pratz; the Prairie Wolf of Gass; the Prairie Wolf and Burrowing Dog of Lewis and Clark, and of Schoolcraft; the Cased Wolves of the Hudson's Bay Company's lists; and the Mecsteh-chaggoneesh of the Cree Indians.

Sir John Richardson states that the northern range of the Prairie Wolf is about the 55th degree of latitude, and that it probably extends southward to Mexico. It associates, according to him, in greater numbers than the Gray Wolf of the same districts; it hunts in packs, and brings forth its young in burrows on the open plain remote from the woods. On the banks of the Saskatchewan these animals start from the earth in great numbers on hearing the report of a gun, and gather round the hunter expectant of the offal of the animal which he has slain. They are much more fleet than the Common Wolves. Sir John Richardson was informed by an experienced hunter who had resided for forty years on the Saskatchewan, that the only animal on the plains which he could not overtake, when mounted on a good horse, was the Prong-Horned Antelope, and that the Prairie Wolf was the next in speed.

C. ochropus, the Coyotl, *Vulpes Indica* of Hernandez ('Hist. Quadr. Novæ Hisp.,' c. xiii.), appears to be the Caygotte of the Mexican Spaniards, and is "most probably," the *Lyciscus Cagottis* of Smith. This appears to be the animal mentioned by Mr. Bullock, in his 'Six Months in Mexico.' "Near Rio Frio," says that traveller and assiduous collector, "we shot several handsome birds, and saw a cayjotte or wild dog, which in size nearly approached the wolf. He stood looking at us at a short distance from the road, and it was not till a gun was fired at him that he deliberately moved off."

Hernandez describes the Coyotl to be an animal unknown to the Old World, with a wolf's head, vivid large and pallid eyes, small and sharp ears, a long black and not thick muzzle, muscular legs, crooked and thick claws, a very rough and thick tail, a noxious bite, approaching in form to the Fox, to which genus it is perhaps to be referred, and intermediate between it and the Wolf in size; for it is twice the size of the fox and less than the wolf, wherefore it is said to attack and kill not only sheep and similar animals, but stags, and sometimes even men. It is covered with brown and white long hair, is sagacious in hunting and vulpine in its manners, and so pertinacious an avenger of wrongs, and so mindful of the abstraction of its prey, that it will recognise the robber after many days, will follow him, and sometimes set upon him with others of its own kind, &c. It is however grateful to its benefactors. It lives in many places of New Spain, and especially in those which are colder. It feeds upon the weaker animals, maize and other frumentaceous vegetables, and sugar-cane.

The Aguara Guazu of D'Azara is the *Canis jubatus* of Cuvier, the Loup Rouge of the French, the *Canis campestris* of the Prince de Wied, and the Maned Aguara, *Chrysocyon jubatus*, of Smith.

D'Azara thus describes this Red Wolf, to which the Payaguas Indians give the name of Paraepaga, and the Chilians that of Culpeu. In Moxos, he says, the animal goes by the appellation of Ocorome.

Length of an adult male exactly 5 feet, that of the tail 19 inches, the hairs being 4 inches long. Height in front 2 feet 10½ inches, behind 2 feet 11 inches; circumference close to the fore legs wanting half an inch of 2 feet, of the middle of the neck 1 foot; and of the head, before the ears, 1 foot 3 inches; the ears 6 inches high, in their broadest part 4 inches, erect, but not exactly sharp, and very thick. From the tip of the muzzle to the ears 9¾ inches, and to the inner angle of the eye 5 inches; the whiskers 2½ inches long, and black. The upper jaw projecting 1 inch; the canine teeth 10 lines long, although they were very much worn; eye small and somewhat sunk; from the eye forwards the muzzle of almost equal thickness to the tip. Under the head a great white spot; long hair within the ears, and extreme half of tail white also. Fore and hind feet to the claws, lower jaw from the corner of the mouth forwards, and extremity of upper jaw, black; rest of the coat clear yellowish-red. Mane commencing at the occiput and continuing erect till beyond the shoulder, 5¾ inches long, red in the first half of each hair, and black in the remainder towards the tip. Hair all over the body, including the belly, except the lower part of the fore legs, very long, and on the extremity of the spine 4½ inches. D'Azara observes that it is neither completely flattened nor very rough, and would make good carpets. Hair of the tail rather bushy and of the same length as on the body.

D'Azara caught four males at different times which were identical, the smallest towards the end of September, which appeared to him to have been whelped at the end of July or the beginning of August. D'Azara's friend Noseda caught another about two months old, and in the hope of domesticating it, fed it on raw beef, which it was unable to digest, and which caused its death. D'Azara and Noseda caught another afterwards, about three months old, and gave it raw beef but seldom; when it was given however the animal threw it up, and to prevent this its meat was cooked, but still it was not digested. This Aguara got loose from its chain and escaped. During its short captivity, if anybody approached, it growled and barked like a dog, but more vehemently and confusedly. It drank by lapping, and when feeding trod on the flesh, which it tore to pieces with its teeth. This animal was fond of rats, sugar-cane, oranges, eggs, and small birds; but did not appear to be attracted by the poultry, which sometimes passed within its reach without its attempting to pounce upon them.

D'Azara further states that in a wild state they do not commit havoc on the herds or smaller flocks; and as they inhabit only the extensive lowlands and marshes of Paraguay as far as the river Plata and near its mouth, he has no doubt that they feed on rats, guinea-pigs, small birds, and certain vegetables, if these fall in their way; but chiefly on snails, toads, frogs, and other reptiles, and on the land-crabs, which are abundant in the plains and sand-banks. They walk with very long paces, run much, and are, D'Azara adds, great plunderers, although they always fly from man, and even from dogs. They are solitary in their habits, and are said to swim well; and in their wild state to utter no sound but 'gouaa,' which they often and loudly repeat so as to be heard at a great distance. The sexes have no very marked difference.

The Aguara Dogs (*Dusicyon* of Smith) are a distinct race; and so are the Aguara Foxes (*Cerdocyon* of the same author).

Jackals.

C. aureus (Linnæus), the Jackal, or Tschakkal, Chacal or Loup Doré of the French, Adive of Buffon.

The dental formula of this species is that of the Dog. The pupil of the eye is round like those of the dog and wolf. Yellowish-gray above, whitish below; thighs and legs yellow; ears ruddy; muzzle very pointed; tail reaching hardly to the heel (properly so called). The colours sometimes vary, and the back and sides are described by Mr. Bennett as of mixed gray and black, and as abruptly and strikingly distinguished from the deep and uniform tawny of the shoulders, haunches, and legs. The head nearly of the same mixed shade with the upper surface of the body.

It is an inhabitant of India, other parts of Asia, and Africa. Cuvier says that Jackals are met with from India and the environs of the Caspian Sea to Guinea, but that it is not certain that they are all of the same species.

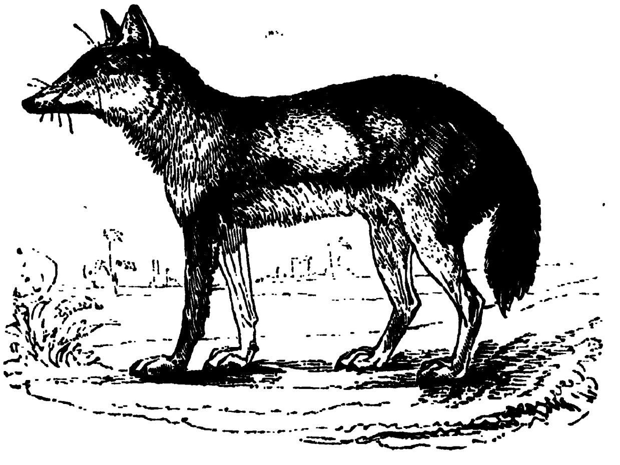
The habits of the Jackal are gregarious, hunting in packs, and the pests of the countries where they are found, and where they burrow in the earth. In their huntings the Jackals will frequently attack the larger quadrupeds, but the smaller animals and the poultry are their most frequent prey. Their cry is very peculiar and piercing. Captain Beechey notices it as having something rather appalling when heard for the first time at night; and he remarks, that as they usually come in packs, the first shriek which is uttered is always the signal for a general chorus. "We hardly know," continues the Captain, "a sound which partakes less of harmony than that which is at present in question; and indeed the sudden burst of the answering long-protracted scream, succeeding immediately to the opening note, is scarcely less impressive than the roll of the thunder-clap immediately after a flash of lightning. The effect of this music is very much increased when the first note is heard in the distance (a circumstance which often occurs), and the answering yell bursts out from several points at once, within a few yards or feet of the place where the auditors are sleeping." These animals are said to devour the dead on the battle-field, and to scratch away the earth from the shallow graves in order to feed on the corpses.

John Hunter ('Phil. Trans.') has recorded the case of a female Jackal which whelped in this country. The period of gestation was about the same as that of the dog, and the whelps were blind at first.

The story of the Jackal being the lion's provider may have arisen from the notion that the yell of the pack gives notice to the lion that prey is on foot, or from the Jackal's being seen to feed on the remnants of the lion's quarry.

Cuvier observes that it is not certain that all the Jackals are similar ('of the same species'); those of Senegal, for example the Dieb, (*Canis anthus*, F. Cuvier), he remarks, stand higher on the legs, and appear to have the muzzle sharper and the tail rather longer.

The offensive odour of the Jackal has been given as one of the reasons against reducing it to a state of domestication. We do not see what advantage is to be derived from such a process, but if it were desirable that objection it seems would not hold. Colonel Sykes, who notices it as the Kholah of the Mahrattas and as being numerous in Dukhun (Deccan), had in his possession at the same time a very large wild male and a domesticated female. The odour of the wild animal was almost unbearable; that of the domesticated Jackal was scarcely perceptible.



Jackal (*Canis aureus*).

Some are of opinion that the 300 foxes between whose tails Samson is said to have put firebrands in order that they might set fire to the crops of the Philistines (Judges, xv. 4, 5) were jackals. Many of the modern oriental names for the last-mentioned animals—Chical of the Turks, Sciagal, Sciugal, Sciachal, or Shacal of the Persians—come very near to the Hebrew word 'Shual.' Hasselquist, speaking of "*Canis aureus*, the Jackcall, Chical of the Turks," says :—"There are greater numbers of this species of fox to be met with than the former (*Canis Vulpes*), particularly near Jaffa, about Gaza, and in Galilee. I leave others to determine which of these is the fox of Samson."

Fossil Canidæ.

The remains of the Dog and Wolf have been found in Great Britain. If there were no historical records to prove that the wolf was once an inhabitant of these islands, its abundant remains would testify to the fact. They were not present in any considerable number in the Bone-Caves of Kirkdale which were so diligently examined by Dr. Buckland, but they have been found at Paviland in Glamorganshire and at Overton near Plymouth. After alluding to the difficulty which was more particularly expressed by Cuvier of distinguishing between the Wolf and the Dog, Professor Owen referring to some specimens from Kent's Hole says :—"The more important points of concordance between the skull from Kent's Hole and those of the existing wolf leave no reasonable ground for doubting their specific identity; and the naturalist who does not admit that the dog and the wolf are of the same species, and who might be disposed to question the reference of the British Fossils described in the present section to the wolf must in that case resort to the hypothesis that there formerly existed in England a wild variety of dog having the low and contracted forehead of the wolf, and which had become extinct before the records of the human race. The conclusion however to which my comparison of the fossil and recent bones of the large *Canidæ* have led me is, that the wolves which our ancestors extirpated were of the same species as those which, at a much more remote period, left their bones in the limestone caverns by the side of the extinct bears and hyænas."

Recognisable remains of the Dog have however been obtained from Bone-Caves. Dr. Schmerling has described and figured an almost entire skull, two right rami of lower jaws, a humerus, ulna, radius, and some smaller bones, indicating two varieties of the domestic dog, from some Bone-Caves near Liège.

CANNA, a genus of plants belonging to the natural order *Marantaceæ*. It has spathaceous flowers, simple anthers attached to the edge of a petal-like filament, an inferior ovary, thick club-shaped erect free style, a linear obtuse stigma. There are several species of this genus, all of which are known by the name of Indian Shot. They are inhabitants of South America and of the East Indies.

C. Indica has the inner limb of the corolla trifid, the segments lanceolate, acuminate, straight. This species, with *C. patens* and *C. coccinea*, are common plants within the tropics on all the continents. In America and Brazil they are known by the common name of Wild Plantains. Their leaves are large and tough, and are mostly chosen for forming envelopes for articles of commerce. Hence the French call these plants Balisiers. The seeds of most of the species are round, black, shining, hard, heavy, and about the sixteenth of an inch in diameter, resembling shot, for which they are sometimes used as a substitute. They are roasted and employed in infusion in the same manner as coffee. They yield also a purple dye.

C. edulis has smooth leaves and stems coloured at the base, the roots tuberous and large, the middle segment of the corolla very short. This is one of the species of the order the rootstock of which is used for making arrowroot. Nearly all the species contain starch in the rootstock, which renders them fit to be used as food after being cooked. The starch is separated by tearing the rootstock in pieces and submitting it to the action of water. The water with the starch suspended is poured off from the ligneous portion of the rootstock, and the starch is afterwards allowed to subside. Clusius says that the *C. lutea* grows in the open air in Spain and Portugal, and that the inhabitants of those countries use the seeds for making rosaries.

Many of the species will bear the open air in the summer in this country. They require a light rich soil, and may be increased by dividing the roots or by sowing the seed. They should be planted out in a warm border early in the summer.

(Loudon, *Encyclopædia of Plants*.)

CANNABINACEÆ, *Hempworts*, the Hemp Tribe, a natural order of Exogenous Plants. This little order which has been separated from *Urticaceæ* embraces two well-known plants, the Hop (*Humulus Lupulus*) and the Hemp (*Cannabis sativa*). They are distinguished from the Nettle Tribe by having a solitary suspended ovule, and a hooked ex-albuminous embryo, with a superior radicle. [HUMULUS; CANNABIS.]

CA'NNABIS (in Greek *Κάνναβις*, and in Latin also *Canñabis*), a genus of plants belonging to the natural order *Cannabinaceæ*.

Cannabis sativa, the Common Hemp, is a plant nearly allied botanically to the nettle, with which it even agrees in its general appearance. It is an annual diœcious plant, with erect nearly-simple stems from 4 to 6 feet high, and covered with rigid hairs. The leaves are either alternate or opposite, digitate, and stalked; the leaflets are five in number, narrow, lanceolate, sharp-pointed, serrated, rough, pale-green on the under side; the uppermost leaves have only three leaflets. The male flowers grow in little bunches at the axils of the upper leaves; they are pendulous from short stalks, and have a calyx of five spreading narrow lanceolate sepals, containing five stamens. The female flowers appear in close leafy clusters at the axils of the upper leaves, and consist of a roundish calyx, split halfway down into two parts, and containing a simple 1-celled ovary terminated by a couple of awl-shaped stigmas. The fruit is a lenticular body, looking like and commonly called a seed.

This is the only species known; it is said to be a native of Persia, and is certainly wild, according to Roxburgh, "among the hills and mountains north of India, as well as common everywhere in the gardens of the natives throughout Asia." It is now universally distributed over the north of Europe. Herodotus, iv. 74, describes it as growing in Scythia, north of the Danube, a country which he had visited. We must from this conclude that the plant is really a native of north and east Europe.

It is from its possessing a remarkably tough kind of woody tissue capable of being manufactured into linen and cordage, that hemp is best known; and for its good qualities in this respect it is unrivalled among the many species possessing similar properties. But it also contains a deleterious narcotic secretion of great energy. If one remains for any length of time amongst a plantation of young hemp, head-ache and vertigo are often the result; in hotter countries these effects are much more violent, a kind of intoxication being speedily produced. Oriental nations have taken advantage of this to add another to the list of intoxicating drugs, which they contrive to substitute for the forbidden wine of western people. The powdered leaves mixed with some kind of aromatic are infused in water and drunk, when a drowsy ecstatic feeling comes on, which is said to be much more agreeable than that produced by opium. The leaves are also mixed with tobacco for smoking. The two chapters of Herod., iv. 74, 75, are curious as to its intoxicating effects, &c. The drug obtained from hemp is called bang, or haschish, or cherris: gangika or ganga, kinnab, subjah, majah, are other names for it. The seeds of hemp abound in a thick mucilage, and are used medicinally for the preparation of emulsions: a useful oil is obtained from them by pressure. The hemp develops its active properties more in warm climates, hence for medicinal purposes it is brought into this country from India under the name of *Cannabis Indica.*

CANNON-BALL-TREE. [COUROUPITA.]

CANTHA'RIDÆ, a family of Coleopterous Insects of the section *Trachelides.* It has the following characters:—Hooks of all the tarsi cleft; antennæ generally filiform; head usually broader than the thorax, and divided posteriorly by an indentation; thorax for the most part narrower behind than before; elytra soft and flexible, and in most of the species inclosing the sides of the abdomen. The genus *Cantharis* may be distinguished from other genera of this family by the following characters:—Antennæ long and filiform, the second joint very short; maxillary palpi short, the joints nearly equal, the terminal joint slightly exceeding the others in bulk; head a little wider than the thorax, which is slightly elongated, and has the anterior part suddenly narrowed, forming as it were a neck; elytra elongate, and somewhat linear.

Cantharis vesicatoria, the Spanish Fly, or Blister-Beetle, is well known for its medical uses. [CANTHARIS VESICATORIA, in ARTS AND SC. DIV.] It is about three-quarters of an inch in length, and of a bright-green colour; the legs and antennæ are bluish-black.

This insect is found but rarely in this country. It appears in the month of June and frequents ash-trees, upon the leaves of which it feeds. *C. vesicatoria* is also found in France, but in Italy and Spain it appears to be most abundant.

When touched these insects feign death, and emit an odour of a highly penetrating nature. Their larvæ live in the ground, and feed upon the roots of plants.

CANTHARIS. [CANTHARIDÆ.]

CANTHARUS, a genus of Acanthopterygious Fishes belonging to the family *Sparidæ.* It has a deep compressed body; a single elongated dorsal fin; teeth of rather small size, numerous, conical, placed in several rows, those of the outer row rather larger and more curved than those forming the inner rows; mouth rather small; branchiostegous rays, six. (Yarrell.) One species of this genus appears on the coasts of Great Britain, the *C. griseus* of Cuvier and Valenciennes. It is the *Sparus lineatus* of Montagu. It is common on the coasts of Kent, Sussex, and Devonshire, where it is called the Black Bream. It is also called the Black Sea-Bream, but it is a different fish from the Sea-Bream (*Pagellus centrodontus*). Mr. Yarrell says, "It enters harbours, and is frequently taken by anglers from rocks and pier-heads." It takes common baits, but seems principally to feed on marine vegetables.

CAOUTCHOUC. [INDIAN-RUBBER.]

CAOUTCHOUC, FOSSIL. [BITUMEN.]

CAPERCALI, CAPERKALLY, or CAPERCALZE, the Scotch name for the Capercail, Wood-Grouse, or Cock of the Wood, the *Tetrao Urogallus* of Linnæus.

Pennant refers this bird to the Coc de Bois, or Faisan Bruyant, of Belon, and the Gallo Cedrone of the Italians; and it is very probable that these and other names, namely, Gallo di Monte, Gallo Selvatico, Gallo Alpestre, Fasan Negro, and Fasiano Alpestre, were applied both to the Caperkally and the Black-Cock, according to the different localities where the species occurred. [BLACK-COCK.] Part of Belon's description of his Coc de Bois—such, for example, as the plume "si noire et reluisant au-dessous du col, et de l'estomach, qu'elle monstre en estre toute changeante," and the tail with the feathers "voultées, c'est à dire courbées en arc, et larges par le bout, ayant quelque petites madrures blanches," might apply to the Black-Cock, while "the size approaching to that of the peacock"—"the head not less than that of a bustard, with the great massive trenchant beak,"—are much more applicable to the Caperkally, which is Le Grand Coq de Bruyères of Brisson, the Coq de Bruyère ou Tetrao of Buffon, Kjader of the 'Fauna Suecica,' Tjaderhona of Hasselquist, the Tetrao Auerhan of Temminck, Auer Hahn of Frisch, Auerwaldhuhn of Bechstein, the Peacock of the Wood (*Pavo sylvestris*) of Giraldus Cambrensis, Capricalca of Sibbald, the Cock of the Mountain or Wood (called by the Venetians Gallo di Montagna) of Willughby, the Cock of the Wood or Mountain of Ray, Wood or Great Grous of Pennant, Ceiliog Coed of the ancient British, *Urogallus seu Tetrao major* of Aldrovand, *Tetrao Urogallus* of Linnæus, and *Urogallus vulgaris* of Fleming.

Temminck says that this bird is numerous in the north of Asia, and in Russia towards Siberia: and that it is common in Livonia, sufficiently abundant in Germany, in Hungary, and in certain parts of the Archipelago: he adds that it is more rare in France, and never found in Holland. Pennant states that these birds are common in Scandinavia, Germany, France, Italy, and several parts of the Alps. It is added in a note, on the authority of Hasselquist, that the bird was shot in the Isle of Milo on a palm-tree, and on that of Belon that it is found in Crete; and it is observed that the English translator of Hasselquist gives a false name to it, calling it Black Game. Mr. Lloyd says that it is to be found in most parts of the Scandinavian peninsula; indeed as far to the north as the pine-tree flourishes, which is very near to the North Cape itself. He adds that the bird is very rare in the more southern of the Swedish provinces.

That it was once frequent in the British Islands there is no doubt, though it is now utterly extinct as a wild British species. Ray says: "Anglia hunc non alit. In Hibernià inveniri dicitur." Pennant writes: "This species is found in no other part of Great Britain than the Highlands of Scotland, north of Inverness, and is very rare even in those parts. It is there known by the name of Capercalze, Auercalze, and in the old law-books Caperkally—the last signifying the Horse of the Woods—this species being, in comparison of others of the genus, pre-eminently large." He also says: "In our country I have seen one specimen, a male, killed in the woods of Mr. Chisolme, to the north of Inverness. About the year 1760 a few were to be found about Thomas Town, in the county of Tipperary, but I suspect that the breed is now extinct in every part of Ireland." Graves (1813) says: "This species is nearly extinct in Great Britain; two instances of its being killed in Scotland within these few years are the only satisfactory accounts we have received of its being recently found in these kingdoms. One was killed by a gentleman of the name of Henderson near Fort William about six years ago, and sent to Dundee; but the vessel that conveyed it to London was detained so long on the passage that the bird became so putrid that only the head and legs could be preserved. The other specimen was shot by Captain Stanton near Burrowstoneness two winters ago; they were both males. Some few are said to be yet remaining in the pine forests of Scotland, and also in the mountainous parts of Ireland." Bewick speaks of it as very rare in Great Britain. In the last edition of Montagu (1833) it is stated that the bird was last seen in 1760 in the woods of Strathglass, that it continued in Strathspey till 1745, and that recent attempts have been made to re-introduce it from Norway without success. Selby (1825) alludes to its extirpation, and omits the species. Jenyns ([illegible]) observes that it was formely abundant in the mountainous forests of Scotland and Ireland, but that it is now extirpated. A living pair came into the possession of the Zoological Society of London, but they did not long survive the loss of liberty.

"A few years ago," writes Mr. Lloyd in his interesting 'Field Sports,' "I procured a brace of those birds, consisting of cock and hen, for a friend of mine, Mr. Thomas Fowell Buxton, the member for Weymouth, then resident at Cromer Hall in Norfolk. After a lapse of a few months the hen laid six eggs, and from these, in process of time, six capercali were produced. The chicks lived until they had attained to a very considerable size, when, owing to the effects, as it was supposed, of a burning sun, to which they had been incautiously exposed, the whole of them, together with the mother, died. On this mishap the old cock, the only survivor, was turned loose into the game preserves, where he remained in a thriving condition for about a year and a half. At last however he also met his doom, though this was supposed to be owing rather to accidental than natural causes."

In further corroboration of the fact that the Capercali will breed when in confinement, we make the following quotation from Mr. Nilsson's work. That gentleman's authority was the öfwer director of Uhr; and the birds alluded to were at a forge in the province of Dalecarlia:—

"They were kept together during the winter in a large loft over a barn, and were fed with corn, and got occasionally a change of fresh spruce-fir, pine, and juniper sprigs. Early in the spring they were let out into an inclosure near the house, protected by a high and close fence, in which were several firs and pines, the common trees of the place. In this inclosure they were never disturbed; and during the sitting season no one approached except the person who laid in the meat, which at that time consisted of barley, besides fresh sprigs of the kinds before mentioned. It is an indispensable rule that they shall have full liberty, and remain entirely undisturbed, if the hens are to sit and hatch their young. As soon as this had occurred, and the brood were out, they were removed to the yard, which was also roomy, and so closely fenced that the young ones could not escape through; and within this fence were hedges and a number of bushes planted. Of the old ones one of the wings was always clipped, to prevent their flying. I have seen several times such broods, both of black game and capercali, eight to twelve young ones belonging to each hen. They were so tame that, like our common hens, they would run forward when corn was thrown to them. They should always have a good supply of sand and fresh water."

M. Greiff gives the following directions for rearing the young:—

"The eggs, usually so called, to be found in ant-hills and stubble, are to be gathered; hard boiled eggs are to be chopped and mixed amongst fine moistened barley-meal; also pea-haulm and trefoil-grass are to be given them for food, and water to drink, which must be placed so that they cannot overturn the pitcher, for they suffer very much if they get wet when they are young. Dry sand and mould they never should be without. When they get larger, and cabbage-leaves, strawberries, cranberries, and blueberries are to be had, they are fond of such food: and when they are full grown they eat barley and wheat; and in winter they should get young shoots of pine and birch-buds. I have seen many people who thought they treated young birds well by giving them juniper berries; but they never resort to this kind of food but in case of necessity."

The following observations of Professor Nilsson show how well this bird is adapted for the game preserve:—

"When the capercali is reared from the time of being a chicken, he frequently becomes as tame as a domestic fowl, and may be safely left by himself. He however seldom loses his natural boldness, and, like the turkey-cock, will often fly at and peck people. He never becomes so tame and familiar as the black-cock. Even in his wild state the capercali frequently forgets his inherent shyness, and will attack people when approaching his place of resort. Mr. Alderberg mentions such an occurrence. During a number of years an old capercali cock had been in the habit of frequenting the estate of Villinge at Wermdö, who, as often as he heard the voice of people in the adjoining wood, had the boldness to station himself on the ground, and, during a continual flapping of his wings, pecked at the legs and feet of those that disturbed his domain."

For the details of the experiment made by Lord Fife in the years 1828, 1829, 1830, and 1831, we must refer the reader to Mr. Wilson's interesting paper in 'Jameson's Journal' for July 1832. Suffice it to say that, after some failures, Mr. Wilson, in August, 1831, saw at Braemar five young Capercali which had been hatched there, and were, with their parents, in good health. The intention of the Thane was, "as soon as some healthy broods had been reared in confinement to liberate a few in the old pine woods of Braemar, and thus eventually to stock with the finest of feathered game the noblest of Scottish forests." In 1844 five young birds were hatched in the aviary of the late Lord Derby at Knowsley.

Temminck makes the food to consist of many sorts of berries, the buds and young shoots of the leaves of trees and of alpine shrubs; also of insects, but rarely of seeds. Mr. Lloyd says that it feeds principally on the leaves of the Scotch fir (Tal), and very rarely on those of the spruce (Gran): also on juniper berries, cranberries, blueberries, and others common to the northern forests, and occasionally in the winter time on the buds of the birch, &c. The young, he says, are for the most part sustained at first on ants, worms, insects, &c.

Temminck says that the nest is formed in high herbage and under bushes, and that the hen lays from 6 to 16 obtuse eggs of a dirty white colour, marked with yellowish spots. Latham states that he is well informed that the nest of one found in Scotland was placed on a Scotch pine: "if so," says Montagu, "it differs from all the genus, who are known to lay their eggs on the bare ground." Mr. Lloyd, who had the best opportunities for ascertaining the fact, observes that the hen makes her nest upon the ground, and lays from 6 to 12 eggs, and that her young keep with her till towards the approach of winter; but that the cocks separate from the mother before the hens. The same author describes, evidently from personal observation, the 'lek,' or play, of the male in the breeding season, and as it is in itself most interesting, and corrects some errors which have gone abroad on the subject, we make no apology for inserting it:

"At this period, and often when the ground is still deeply covered with snow, the cock stations himself on a pine and commences his love-song, or play as it is termed in Sweden, to attract the hens about him. This is usually from the first dawn of day to sunrise, or from a little after sunset until it is quite dark. The time however more or less depends upon the mildness of the weather, and the advanced state of the season.

"During his play the neck of the capercali is stretched out, his tail is raised and spread like a fan, his wings droop, his feathers are ruffled up, and, in short, he much resembles in appearance an angry turkey-cock. He begins his play with a call something resembling 'peller, peller, peller;' these sounds he repeats at first at some little intervals; but as he proceeds they increase in rapidity until at last, and after perhaps the lapse of a minute or so, he makes a sort of gulp in his throat, and finishes with sucking in as it were his breath.

"During the continuance of this latter process, which only lasts a few seconds, the head of the capercali is thrown up, his eyes are partially closed and his whole appearance would denote that he is worked up into an agony of passion. At this time his faculties are much absorbed, and it is not difficult to approach him: many indeed, and among the rest Mr. Nilsson, assert that the capercali can then neither see nor hear; and that he is not aware of the report or flash of a gun, even if fired immediately near to him. To this assertion I cannot agree, for though it is true that if the capercali has not been much disturbed previously he is not easily frightened during the last notes, if so it may be termed, of his play; should the contrary be the case, he is constantly on the watch, and I have reason to know that even at that time, if noise be made, or that a person exposes himself incautiously, he takes alarm and immediately flies.

"The play of the capercali is not loud, and should there be wind stirring in the trees at the time, it cannot be heard at any considerable distance. Indeed during the calmest and most favourable weather it is not audible at more than two or three hundred paces.

"On hearing the call of the cock, the hens, whose cry in some degree resembles the croak of the raven, or rather perhaps the sounds 'gock, gock, gock,' assemble from all parts of the surrounding forest. The male bird now descends from the eminence on which he was perched to the ground, where he and his female friends join company. The capercali does not play indiscriminately over the forest, but he has his certain stations, 'Tjador-lek,' which may perhaps be rendered his playing grounds. These however are often of some little extent. Here, unless very much persecuted, the song of these birds may be heard in the spring for years together. The capercali does not during his play confine himself to any particular tree, as Mr. Nilsson asserts to be the case, for on the contrary it is seldom he is to be met with exactly on the same spot for two days in succession.

"On these lek several capercali may occasionally be heard playing at the same time; Mr. Greiff, in his quaint way, observes 'it then goes gloriously.' But so long as the old male birds are alive they will not, it is said, permit the young ones or those of the preceding season to play. Should the old birds however be killed, the young ones in the course of a day or two usually open their pipes. Combats, as it may be supposed, not unfrequently take place on these occasions, though I do not recollect having heard of more than two of those birds being engaged at the same time.

"Though altogether contrary to law, it is now that the greatest slaughter is committed among the capercali; for any lump of a fellow who has strength to draw a trigger may, with a little instruction, manage to knock them down. But as the plan of shooting these noble birds during their play is something curious I shall do my best to describe it.

"It being first ascertained where the lek is situated, which is commonly known to the peasants and others in the vicinity, the sportsman (if so he may be called) proceeds to the spot, and listens in profound silence until he hears the call of the cock. So long however as the bird only repeats his commencing sound he must, if he be at all near to him, remain stationary; but the instant the capercali comes to the wind-up, the gulp, &c., during which, as I have said, his faculties of both seeing and hearing are in a degree absorbed, then he may advance a little. But this note lasts so short a time that the sportsman is seldom able to take more than three or four steps before it ceases, for the instant that is the case he must again halt, and if in an exposed situation remain fixed like a statue. This is absolutely necessary, for during his play, excepting when making the gulp, &c., the capercali is exceedingly watchful, and easily takes the alarm. If all remain quiet, the bird usually goes on again immediately with his first strain; and when he once more comes to the final note, the sportsman advances as before, and so on, until he gets within range of shot.

"To become a proficient at this sport requires a good deal of practice. In the first place a person must know how to take advantage of the ground when advancing upon the capercali, for, if full daylight, this is hardly practicable (whatever may be said to the contrary) in exposed situations; and in the next, that he may not move forward excepting upon the note which is so fatal to that bird. This is likely enough to happen if it be an old cock that has been previously exposed to shots, for he often runs on, as I have repeatedly heard him, with 'peller, peller, peller,' until one supposes he is just coming to the gulp, when he suddenly makes a full stop. If therefore a person was then incautiously to advance he would in all probability instantly take to flight.

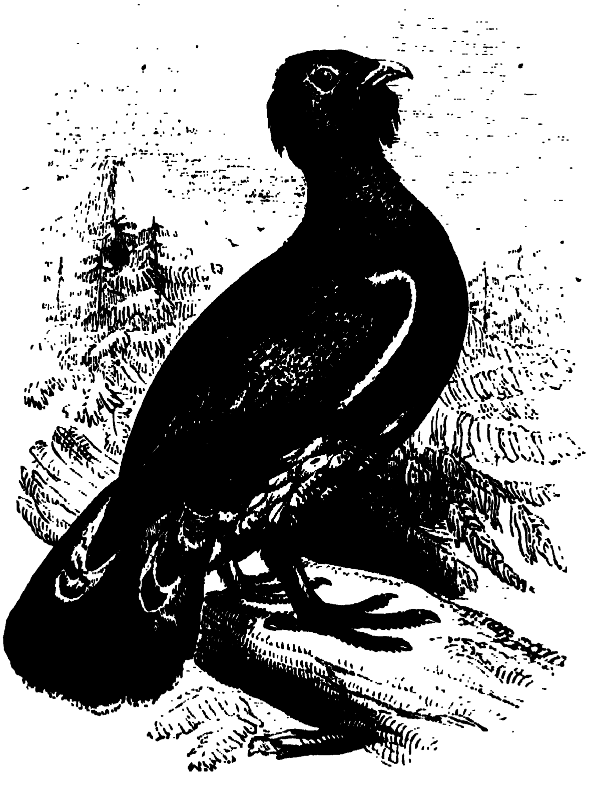
"At the lek the cocks most commonly fall the sacrifice; for the hens, as well from their colour more resembling the foliage of the trees as from the sportsman having larger and better game in view, usually escape. This is a fortunate circumstance; as were a proportionate slaughter to take place among the latter as the former, the breed in many parts of the Scandinavian peninsula would soon be exterminated.

"Though this plan of shooting the capercali during the spring is common throughout most parts of Scandinavia, I am told that in Norrland and Wästerbotten, from whence Stockholm is furnished with its principal supplies of game, that destructive practice is not generally adopted. This arises from the people in those districts having sense enough to know that if they kill too many of the cocks in the spring, there is little probability of there being a good breed during the succeeding autumn."

Our limits will not permit us to enter into the details of the more legitimate chace, which will be found in Mr. Lloyd's book: suffice it to say that the rifle is the instrument used by the fair sportsman, and that in the course of his sport Mr. Lloyd observed, that when the weather is cold and the snow loose and soft, the capercali not unfrequently buries himself beneath its surface during the night season, and once in a while he found the bird in that situation in the day-time; so that the old wood-cuts of grouse nestling under the snow are not entirely without foundation. Mr. Lloyd remarks that the capercali often becomes the prey of the great horned owl. [Bubo.]

As an article of food the capercali is justly admired; and the rapidity of communication consequent upon the increased and increasing development of the powers of steam now furnishes annually the shops of the London poulterers with a supply in the spring. Some assert that at certain seasons the flavour of the bird is rendered extremely unpleasant by the fir-buds which then form its food; but those which we have tasted were excellent. The hen, though smaller, is in our opinion preferable to the cock. In preparing the bird for roasting, the breast should be skinned and a veal-caul spread over it.

Male.—Elongated feathers of the throat black; the rest of the head and neck ashy black; eyebrows red; wings and scapulars brown, sprinkled with small black dots; breast changeable green; belly and abdomen black, with white spots; rump and flanks sprinkled with ashy zigzags on a black ground; tail-feathers black, with some small white spots disposed at about two inches from their extremities; bill nearly 3 inches long, very strong, hooked, and of a whitish horn-colour; iris clear brown; length about 2 feet 10 inches; usual weight from 9 to 12 lbs. Graves says that the fine specimen from which his figure was taken measured 3 feet 1⅛ inch in length, 7 feet 5 inches in breadth, and weighed 15 lbs. 2½ ounces.



Capercali (*Tetrao Urogallus*), male.

Female.—Striped and spotted with red or bay, black and white; feathers of the head bright ruddy, and those of the breast deep red; tail ruddy, striped with black; bill blackish-brown; size about one-third less than that of the male.

Young Males, after their first Moult.—Breast of a less lustrous green than in the old birds, and the ash-colour predominating over the black; some red feathers spotted with black are scattered irregularly over the plumage. Before the first moult the young males resemble the females.

Mr. Lloyd says that the capercali occasionally breed with the black game, the product of which are in Sweden called Racklehanen: these partake of the leading characters of both species; but their size and colour greatly depend upon whether the connection was between the capercali cock and the gray hen, or vice versâ. "Out of twenty racklehanar, which is the male, two, according to Mr. Falk, are not alike; and the difference of colour observable among the racklehönan, which is the female, but very rare, is still greater. Racklehanen are very seldom to be met with. During my stay in Wermeland, however, Mr. Falk had two of these birds in his possession, and I myself shot a third." The bird here alluded to was probably the Rakelhan (*Tetrao medius* of Meyer), which Temminck observes, some naturalists, and recently M. Nilsson, have erroneously considered a hybrid between the Capercali and Black-Cock. But at Braemar, in 1828, in consequence of the death of the hen which had been imported with a cock, a common barn-door hen was introduced to the latter. The result, according to Mr. Wilson, was, that she laid several eggs, which were placed under other hens; but from these eggs only a single bird was hatched, and when it was first observed it was found lying dead. It was, however, an evident mule or hybrid, and showed such unequivocal marks of the capercali character as could not be mistaken.

CAPERS, the young flower-buds of *Capparis spinosa.* [Capparidaceæ.]

CAPILLAIRE. [Adiantum.]

CAPILLARY VESSELS, so called from their hair-like minuteness. The blood-vessels of the body consist of arteries and veins, the arteries carrying the blood from the heart, and the veins returning it to the heart. The blood-vessels that supply the body are arborescent, that is, the branches which spring from the aorta successively increase in number and diminish in size as they proceed from the heart towards their ultimate terminations in the system. In like manner the veins divide. These ultimate terminations of the arteries, together with the first origins of the veins, constitute a peculiar system of vessels termed the Capillary System. These capillary vessels are too minute to be detected by the naked eye; but in the transparent parts of the body of a living animal, when brought under the field of the microscope, they become perfectly visible, as in the web of the frog's foot, the mesentery of the rabbit, the tail of the tadpole, &c. The greater number of the arteries and veins are then seen to be directly continuous with each other, no substance intervening between the two orders of vessels. No words can describe the beauty of the sight presented by the flow of the vital fluid through these minute tubes. Myriads of vessels not visible to the naked eye instantly come into view. In one case the direction of a minute artery being suddenly altered it is reflected on itself, and thus becomes an incipient vein; in other cases minute branches are sent off from an artery into a parallel vein; and in a third case several minute arterial ramifications are continuous with a single vein. The venous capillaries are generally larger and more numerous than the arterial, and they communicate more freely with each other.

The minute capillary vessels are totally distinct both in structure and office from the large trunks from which they spring. All the tunics of the capillary arteries diminish in thickness and strength as the tubes lessen in size, but more especially the middle or fibrous coat [Artery]; "but this coat may still be distinguished by its colour in the transverse section of any artery whose internal diameter is not less than the tenth of a line, but it entirely disappears in vessels too small and too remote to receive the wave of blood in a manifest jet. But while the membranous tunics diminish, the nervous filaments distributed to them increase. The smaller and thinner the capillary the greater the proportionate quantity of its nervous matter; and this is most manifest in organs of the greatest irritability. The coats of the capillaries successively becoming thinner and thinner at length disappear altogether, and the vessels ultimately terminate in membraneless canals formed in the substance of the tissues."

Of the capillary arteries which it has been stated terminate by direct communication with the capillary veins, some are large enough to admit of three or four of the red particles of the blood [Blood] abreast; the diameter of others is sufficient to admit only of one; whilst others are so small that they can transmit nothing but the serum of the blood. Their prevalent size in the human body may be stated at from $\frac{1}{3500}$ths to $\frac{1}{2000}$ths of an inch when naturally filled with blood. As long as the capillary is of sufficient magnitude to receive three or four blood globules abreast, it is evident that it possesses regular parietes; but by far the greater number, before they communicate with veins, lose altogether their membranous coats. There are no visible openings or pores in the sides or ends of the capillaries by means of which the blood can be extravasated preparatory to its being imbibed by the veins. There is nowhere apparent a sudden passage of the arterial into the venous stream, no abrupt boundary between the division of the two systems. The arterial streamlet winds through long routes, and describes numerous turns before it assumes the nature and takes the direction of a venous streamlet. The ultimate capillary rarely passes from a large arterial into a large venous branch.

The capillary network differs in the size and width of the meshes in different parts. It is very close in the lungs and in the choroid coat of the eye; close also in muscle, in the skin, and in most parts of the mucous membrane, in glands and secreting structures, and in the gray part of the brain and spinal cord. On the other hand, it has wide meshes and comparatively few vessels in the ligaments, tendons, and other allied textures. (Sharpey.)

All the great organic functions of the living body are performed mainly by the capillary vessels. Their action is essential to secretion, nutrition, calorification, and every other process which is indispensable to the support of life. From experiment, it has been inferred that these vessels possess an active contractile power altogether independent of the impulse derived from the heart. Under the ordinary condition of the circulation, the blood indeed flows through these capillary vessels by the force communicated to the circulating fluid by the contraction of the heart; but the evidence brought forward seems to indicate that stimulants of various kinds applied directly to the capillary arteries, without in the least affecting the heart's action, are capable of modifying to a considerable extent the action of the capillaries; sometimes causing them to contract and at other times to dilate; sometimes quickening the flow of the blood through them; at other times retarding it, and not unfrequently altogether arresting its progress.

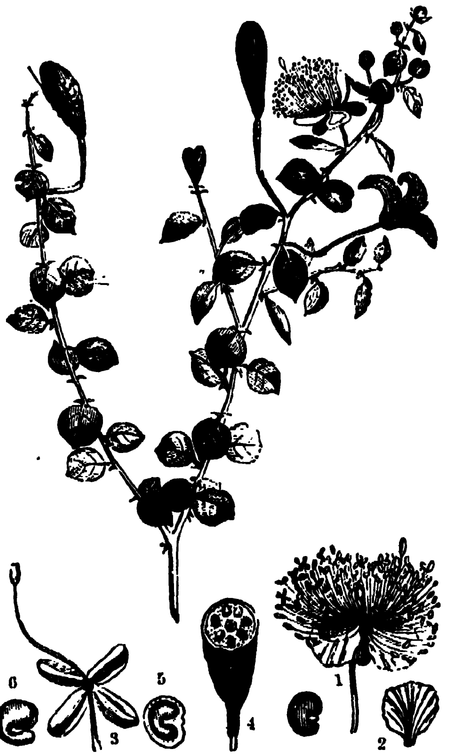
For an account of the development of the capillaries, see BLOOD-VESSELS.

CAPI'TULUM, a head of flowers, a particular form of inflorescence. Theoretically botanists consider it an undeveloped spike, the axis of which becomes a receptacle, and the external empty bracts an involucre. It really consists of a number of small flowers, which in the majority of plants are arranged upon an elongated stalk, or arranged upon a flattened or horizontal stalk. The Dandelion, the Daisy, the Groundsel, and all *Compositæ*, have an inflorescence of this nature; it is vulgarly looked upon as a flower.

CAPNEA. [ACTINIADÆ.]

CAPPARIDA'CEÆ, *Capparids*, the Caper Tribe, a natural order of Dicotyledonous Polypetalous Plants, having a superior fruit, parietal placentæ, an embryo curved upon itself, without albumen, four petals and sepals, a great number of stamens, and an ovary elevated upon a long stalk. They are known from *Cruciferæ* by their indefinite stamens and reniform seeds. All of them appear to be more or less acrid. They are bushes or herbs found all over the tropics, and not extending in many places beyond them. Egypt and the south of Europe, which are inhabited by *Capparis spinosa* and similar species, offer the greatest exceptions to the rule.

Some of the American species of *Capparidaceæ* are very poisonous; others act as vesicatories; and a few are merely stimulant. To the latter class belongs the *Capparis spinosa* of the south of Europe. This plant grows naturally upon rocks and ruins all over the south of France and Italy, rendering them inconceivably gay with its large white blossoms, from the centre of each of which there springs a long tassel of deep lilac stamens. The flower-buds constitute the Capers of the shops, the quality of which depends exclusively upon the age at which they are gathered, the smallest and youngest being the dearest and most delicate, and the largest and oldest the coarsest and cheapest. On an average each plant of the caper-bush gives a pound of buds. The consumption of capers in this country is inconsiderable, not amounting to more than about 60,000 lbs. a year.



Caper-Tree (*Capparis spinosa*).

1, An expanded flower; 2, a petal; 3, a calyx with the stalked ovary; 4, a horizontal section of the fruit; 5, a longitudinal section of the seed; 6, an embryo extracted from the seed-coat.

Several other species of *Capparis* possess stimulating properties. There is a plant found in the neighbourhood of Carthagena called Fruta de Buno, supposed to be a *Capparis*, the fruit of which is extremely poisonous. The fruits of a species of *Cratæva* are eaten. *Polanisia icosandra* acts as a vesicatory. The root of *Cleome dodecandra* is used as a vermifuge in the United States. The order has 28 genera and about 340 species.

CAPREÆ, a sub-tribe of the family *Bovidæ* amongst the Ruminant *Mammalia*, and equivalent to the sub-tribes *Boreæ* [BOVIDÆ], *Antilopeæ*, *Strepsiceræ* [ANTILOPEÆ], and *Oveæ* [OVEÆ], according to Dr. Gray's arrangement of the *Mammalia* in the British Museum. The *Capreæ* include what are commonly known by the name of Goats. The classification of these animals has been the cause of much difference of opinion.

Ray established three genera of Ruminants with bisulcated hoofs. 1. *Bovinum genus*—the Oxen. 2. *Ovinum genus*—the Sheep. 3. *Caprinum genus*—the Goats; comprising the Common Goat, the Ibex, the Chamois, the Gazelles, &c.

Klein's second family of quadrupeds consisted of those which have a divided horny hoof. The type of the first genus was the Ox; of the second, the Sheep; of the third, the Goat; of the fourth, the Stag; and of the fifth, the Hog.

Brisson's fifth order consisted of those quadrupeds which have no incisor teeth in the upper jaw, but have eight in the lower jaw, and the hoof cloven. The first section consists of those which have simple horns; and comprises, as genera, the Giraffe, the Goat, the Sheep, and the Ox. The quadrupeds with branched horns, the Stags, follow.

Linnæus in his last edition (the 12th) makes *Capra* the fourth genus of his fifth order (*Pecora*), placing it between *Cervus* and *Ovis*: the genus contained the species *Hircus*, *Ibex*, *Mambrica* (Syrian Goat), *Rupicapra* (Chamois), &c., including some of the Antelopes and *Capra Ammon* (*Tragelaphus* and *Musimon* of Gesner).

Gmelin, in the 13th edition of the 'Systema Naturæ,' arranges the genus *Capra* under the same order, between *Antilope* and *Ovis*, to which latter genus he transfers the Musmon, *Capra Ammon* (Gmel.) of Linnæus, *Ovis Ammon* of Gmelin.

Pennant, in the first and third edition of his 'Synopsis,' placed the Goats between the Sheep and the Giraffe, the latter being followed by the Antelopes: in his 'British Zoology' the Goats are arranged between the Sheep and the Deer.

M. Lesson, in his 'Manuel' (1827), arranges the *Capridæ* (Les Caprées) between the *Bovidæ* (Les Bovinées) and the *Ovidæ* (Les Ovinées).

In both his editions of the 'Règne Animal,' Cuvier gives the Goats (*Capra*) the same position under his Ruminants à Cornes Creuses (*Cavicornia*—Hollow-Horned Ruminants, or those whose horns have a bony core), namely, between *Antilope* and *Ovis*.

Fischer (1829) arranges the genus *Capra* (which he divides into two sections—1, *Barbatæ*, *Capræ* of authors; 2, *Imberbes*, *Oves* of authors) between *Antilope* and *Bos*.

Dr. J. E. Gray, as we have seen, places *Capra* among the *Bovidæ*. In his interesting 'Spicilegia Zoologica' (1830), where he figures the female of the Nubian Goat, the genus appears under that family. He had previously so arranged it in the 'Annals of Philosophy' (1825); and Mr. W. S. M'Leay, in his paper 'On the Comparative Anatomy of certain Birds of Cuba' ('Linnæan Transactions'), speaking of the *Mammalia*, observes that the normal and aberrant groups were distinguished and named by Aristotle in his 'Historia Animalium,' but had not, to his knowledge, appeared again in any work until Dr. Gray had the honour of reviving them in the 'Annals of Philosophy.'

Referring our readers to the works of Messrs. F. Cuvier, De Blainville, Desmarest, Desmoulins, Erxleben, Geoffroy, Hasselquist, Illiger, Lichtenstein, Meyer, Schreber, Shaw, Zimmermann, and others, for their views on this subject, which, however interesting and desirable for the student, our limits will not permit us to dwell on here, we proceed to notice the observations of Mr. Hodgson in the 'Zoological Proceedings' for 1834.

Mr. Hodgson, after remarking on the difficulty experienced by zoologists in the determination of distinctive marks adequate for the separation of the genera *Antilope*, *Capra*, and *Ovis*, insists that, as he has shown, the character founded on the presumed absence of cavities in the cores of the horns connected with the frontal sinus is incorrect, and he conceives that the value of the characters which are generally admitted by authors as distinguishing between the genera *Capra* and *Ovis* may be tested by a comparison of the wild race of either genus which belongs to the Himalaya. He then describes *Capra Jhâral*, which is "clad in close short hair, and without the least vestige of a beard," as related to the Alpine *Ægagri* and to *Capra Jemlaica* and *Ovis Nahoor* (Hodgson), placing them both under the tribe *Capridæ* (H. Smith); and having completed the description of this wild goat and wild sheep, he proceeds to exhibit the points of difference and of resemblance between the two in the following table:—

Goat.	*Sheep.*
Whole structure stronger and more compact.	Less so.
Limbs thicker and more rigid.	Feebler and more slender.
Hoofs higher and more compact.	Lower and less so.
False hoofs well developed.	Evanescent.
Head smaller and finer.	Longer and heavier.
Facial line straight.	Chaffron arched.
Ears shorter and rounded.	Longer and pointed.
Tail short, flat, nude below.	Longer, less depressed, and half nude only.
Withers higher than croup.	Croup higher.
Fore legs stronger than hind.	Fore and hind equal.
Croup sloped off.	Not so.
Odorous.	Not so.
Nose moister, with nares short and wide.	Less moist, longer, and narrower.
Horns of medial size, keeled, and turned upwards.	Horns very large, not keeled, and turned to the sides.
Eye darker and keener.	Paler and duller.
Hair long and unequal.	Short and equal.
Back arched.	Back straight.
Bears change of climate well.	Bears it ill.
Is eminently curious, capricious, and confident.	Is incurious, staid, and timid.
Barks trees with its horns, feeding on the peel and on aromatic herbs.	Does not bark trees, and is less addicted to aromatics.
In fighting, rears itself on its hind legs, and lets the weight of its body fall on the adversary.	In fighting, runs a tilt, adding the force of impulse to that of weight.

In describing the wild sheep, Mr. Hodgson observes that the horns are inserted high above the orbits on the crown of the forehead, touching nearly at the base with their whole depth, and carrying the frontal bones very high up between them, the parietals being depressed in an equal degree. The goat's skull has, he states, the same form, but less strikingly developed; and he seems to think that this form of the skull would afford a just and general mark to separate *Ovis* and *Capra* from *Cervus* and *Antilope*, remarking that there is a gradation of characters in this respect among the Antelopes tending to the Caprine type in their general structure. Mr. Hodgson thus concludes: "The goat and sheep have in common hair and wool; no beard; no suborbital sinuses; evanescent muzzle; no inguinal pores; horns in contact at the top of the head; knees and sternum callous; angular and transversely wrinkled horns; striated ears; two teats only in the females; horns in both sexes; and, lastly, incisors of precisely the same form. Of the various diagnostics then proposed by Colonel Hamilton Smith, it would seem that the following only can be perfectly relied on to separate *Ovis* from *Capra*:—slender limbs; longer pointed ears; chaffron arched; nares long and oblique; very voluminous horns, turned laterally with double flexures. I should add myself the strong and invariable distinction—males not odorous, as opposed to the males odorous of the genus *Capra*. But after all there are no physical distinctions at all equivalent to the moral ones so finely and truly delineated by Buffon, and which, notwithstanding what Colonel H. Smith urges in favour of the courage and activity of sheep, will for ever continue to be recognised as the only essential diagnostics of the two genera."

Mr. Swainson ('Classification of Quadrupeds,' 1835) places the Goats (*Capra*) between the *Bovidæ*, or Bovine Family, and the Sheep (*Ovis*).

In an interesting paper on the *Ruminantia* ('Zoological Proceedings'), Mr. Ogilby, after observing on the first introduction by Illiger of the consideration of the muzzle and lachrymal sinus into the definitions of the genera *Antilope*, *Capra*, and *Bos*, and the application of those principles by Messrs. Lichtenstein, De Blainville, Desmarest, and Hamilton Smith, in the subdivision of the artificial genus *Antilope* into something more nearly approaching to natural groups (a reform but partial in its operation, and leaving the root of the evil untouched), makes *Capridæ*, which he places between *Moschidæ* and *Bovidæ*, the fourth family of the order *Ruminantia*.

The following is Dr. Gray's definition of the sub-tribe *Capreæ*:—Forehead convex, elevated behind; chin of males bearded; suborbital sinus none. Horns erect, compressed, curved backwards and rather outwards, and furnished with a longitudinal keel in front, deeper than wide at the base, and with transverse ridges in front. Hoofs four-sided, scarcely higher before than behind. The skull has a small suborbital fissure, no fossa; the masseteric ridge ascending high before the orbit; the auditory bulla prominent and compressed; the basioccipital flat, with its processes developed; the middle incisors not expanded; the molars without supplemental lobes. The occipital plane of skull forms an acute angle with frontal plane. Cores of horns thick, porous, cellular; horns seated superiorly on the crest of the forehead, and by their union covering the top of the head. Canine teeth wanting. Teats two, rarely four. The males have a strong stench; they butt, first raising themselves on their hind legs and then coming down sideways against their enemies.

The following is a synopsis of the genera of *Capreæ*:—

A. Muffle Naked.

1. *Hemitragus.* Horns trigonal, compressed, and knotted in front.
2. *Kemas.* Horns square, flat, and cross-ridged in front.

B. Muffle Hairy.

3. *Ægoceros.* Horns roundish, conical.
4. *Capra.* Horns square, flat, and nodose in front.
5. *Hircus.* Horns trigonal, compressed, sharp-edged, and knotted in front.

Dr. Gray refers the Common Goat, which must be taken as the type of the family, to the last genus, of which it is the only species.

Hircus Ægagrus, the Goat, is Ἄιξ (ὁ καὶ ἡ, but generally used for the female), *τράγος*, *χίμαρος* (the male), *ἔριφος* (young male kid of three or four months), *χίμαιρα* (young female before its first winter), of the Greeks; *Caper*, and *Hircus* (male), *Capra* (female), *Hœdus* or *Hædus* (a young male kid), *Hœdulus* or *Hœdillus* (a very young male kid, or kidling, *ἔριφος*), *Capella* (female kid), of the Romans; Becco (male), Capra (female), Capretto and Caprettino (kid and kidling), of the Italians; Bouc (male), Chèvre (female), Chevreau (kid), of the French; Cabron (male), Cabra (female), Cabrito (kid), of the Spanish; Cabram (male), Cabra (female), Cabrito (kid), of the Portuguese; Bock (male), Geisz (female), Bocklein (kid), of the Germans; Bok (male), Giyt (female), of the Dutch; Bock (male), Geet (female), Küdh (kid), of the Swedes; Buk, Geedebuk (male), Geed (female), Kid (kid), of the Danes; Bwch (male), Gafr (female), Mynn (kid), of the ancient Britons. It is the *Capra Hircus* of Linnæus; the *Capra Caucasia*, H. Smith; *Ægoceros Capra*, Pallas; *Capra Ægagrus*, Gmelin.

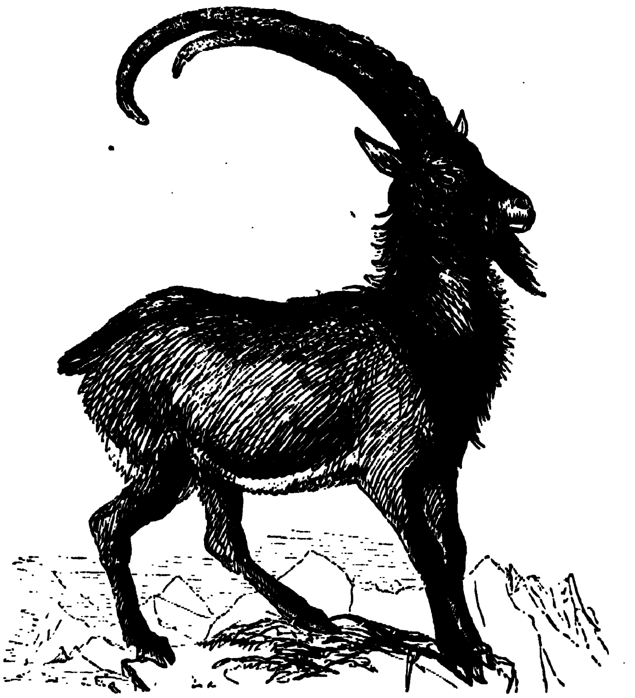
The varieties of this animal are very numerous; and many of these are regarded by writers on natural history as species.

The Goat affords another example of the uncertainty which clouds the history of our domestic animals; and to this day zoologists are not entirely agreed as to the species from which it is derived. Professor Bell, in his 'History of British Quadrupeds,' says,—"The opinions of naturalists have been much divided respecting the original stock of our domestic goat; some referring it to the *Ægagrus* and others to the Ibex. Buffon appears to have adopted the latter opinion; but most modern zoologists who have paid much attention to the question, and who have brought to the consideration of it all the helps which recent discoveries in philosophical zoology have furnished, have leaned to the belief that the *Ægagrus*, or wild goat of the mountains of Caucasus and of Persia, is the true original stock. The zoological characters of this animal certainly bear a closer resemblance to those of the domestic breeds; and it is worthy of remark that the horns of the Persian domestic goat, though smaller, are similar in form to those of the Paseng, or *Ægagrus*. The arguments which have been urged from the intermixture of the Ibex with the common goat are at present of little value, as the facts recorded are very deficient. The large goats which are reported to have been brought from the Alps and the Pyrenees to the Garden of Plants in Paris, and which were stated to have been wild, were probably the progeny of the Ibex with the common goat, as there is no proof of the existence of the true *Ægagrus* in Europe. These were found to be capable of producing offspring, and the details are given by M. Fred. Cuvier with great clearness; but the old fault still remains—the question is not set at rest by these observations; for we are only informed that they produce offspring, without any statement whether they will breed inter se, or only with the common goat. The progeny however were either prematurely brought forth, or lived only a short time in a sick or languishing condition. Surrounded by these doubts, and without the power of satisfactorily solving them, it is better perhaps to leave the question to be decided by future experiments, should the opportunity ever occur of determining the results of interbreeding between the Ibex, the *Ægagrus*, and the common goat, particularly with reference to the mutual fertility of the offspring."

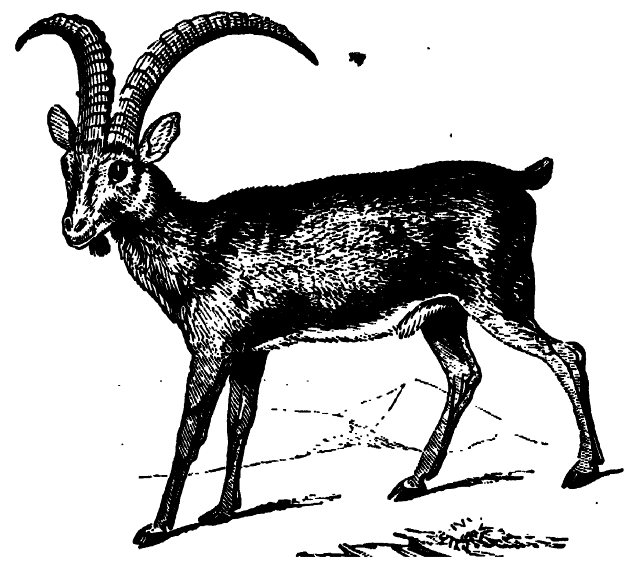
Buffon's opinion is not very clearly stated, nor is it certain that he had a very distinct idea on the subject. Sonini, in his 'Travels in Greece and Turkey,' after speaking of the wild solitudes that surround the Convent of St. John at Cape Malacca, in Candia, says: "Covies of red partridges delight in these inaccessible mountains, and there they live in safety. There also are to be seen wild goats, which leap from rock to rock with admirable address and agility. These wild goats, which are to be met with in the Isle of Candia, and several other islands of the same sea, are of the Bouquetin (*Capra Ibex*, Linn.), or mountain-goat species. The modern Greeks, as has been done by their ancestors, confound the Bouquetin and the Chamois under the same denomination of Wild Goat. The French habituated to the Levant also knew them by no other denomination than that of Chèvre Sauvage. It is to be presumed, in fact, that Buffon himself imagined that these two animals are not of a species different from that of the domestic goat."

Linnæus, in his 'Systema Naturæ,' (12th edition) gives the goat (*Capra Hircus*) an oriental origin; but seems to consider it as a distinct species. He says of it: "Habitat in Oriente in montosis Hircus et Capra cum Hœdo, victitans ramulis variis frondibusque arborum, lichenibus; hospitatur in Europâ." He does not mention the *Ægagrus*, but gives the Ibex (*Capra Ibex*) as a species.

Gmelin ('Syst. Nat.,' ed. 13) gives *Ægagrus* as the first species of the genus *Capra*, and it is followed by *Hircus*. Cuvier, in both editions, considers the Paseng (*C. Ægagrus*) to be the parent-stock of all the varieties of the domestic goat. He adverts to the Paseng as inhabiting the mountains of Persia in troops, and to the Oriental Bezoar as a concretion found in its intestines. Fischer speaks of the *Ægagrus* as being, without doubt, the parent of our Domestic Goat. Whilst upon this inquiry we must not omit the Jemlah Goat (*Capra Jemlaica*, of Hamilton Smith), which is said to inhabit the district of Jemlah, between the sources of the Sargew and the Sampoo that is,



Paseng (*Hircus Ægagrus*, Gray).

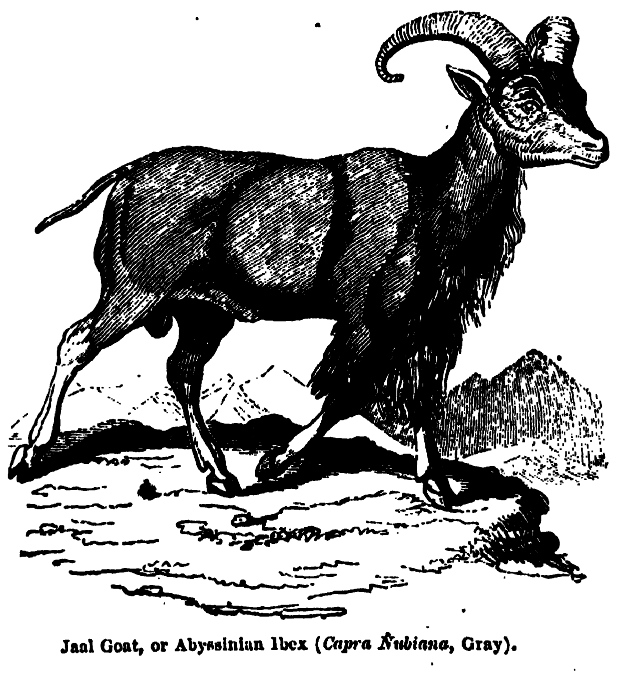


Ibex (*Capra Ibex*, Gray).

says Colonel Smith, the most elevated range of Central Asia, forming the nucleus between the western and south-eastern branches of the Himalaya Mountains. This animal appears to be the same as the Jhâral of the Nepaulese, *Capra Jhâral* (*Hemitragus Jemlaicus*, Gray,) described by Mr. Hodgson ('Zool. Proc.,' 1834), from a fine male specimen kept in his garden at Nepaul. He states that the Jhâral is found wild in the Kachâr region, in small flocks, or solitarily, and gives its character as bold, capricious, wanton, eminently scansorial, pugnacious, and easily tamed and acclimatised in foreign parts. He remarks that the Jhâral has a close affinity, by the character of the horns, to the Alpine *Ægagri* and still more nearly, in other respects, to *Capra Jemlaica*. It differs, he observes, from the former by the less volume of the horns, by their smooth anterior edge, and by the absence of the beard; from the latter, by the horns being much less compressed, not turned inwards at the points, nor nodose. He adds, that the Jhâral breeds with the Domestic Goat, and more nearly resembles the ordinary types of the tame races than any wild species yet discovered.

"No animal," says Pennant, "seems so subject to varieties (the dog excepted) as the Goat;" nor did its multitudinous transfigurations escape Pliny (lib. viii., c. 53). Cuvier observes that the Domestic Goat, *Capra Hircus*, varies infinitely in stature, colour, length, and fineness of the hair, and in size and even number of the horns. The goats of Angora, in Cappadocia, with their soft and silky hair, and those of Tibet, whose delicate wool is manufactured into the shawls (cachemires) so highly prized by the French beauties, are especially alluded to by him. To enumerate all the varieties would be to exceed our limits. The Angora Goat, which inhabits the tract that surrounds Angora and Beibazar, in Asiatic Turkey, where the goatherds bestow much care on their flocks, frequently combing and washing them, loses, it appears, the delicacy of its hairy covering when exposed to a change of climate and pasture; and Pennant hints his suspicions that the design of the Baron Alstroemer, a patriotic Swede, who imported some into his own country to propagate the breed for the sake of their hair, turned out fruitless. A spirited attempt to acclimatise the Cashmere Goat was made by an English gentleman, Mr. Towers, some years ago. The Cashmere Goats, which lived some time in the Gardens of the Zoological Society, and at the farm on Kingston-Hill, certainly did not appear to have suffered in the fineness of their coats; but it is one thing to keep an imported individual by care and attention in the same state, and another to carry on the breed from generation to generation in its pristine beauty, under a different sky and on a strange pasture. We have indeed been informed that the flock of Mr. Towers amounted to about forty, and that the shawls made from the produce of their hides were excellent. One of these shawls was presented to Queen Adelaide. The importance of this manufacture to the people of Cashmere may be estimated from the alleged fact that 16,000 looms are there in constant work, each loom giving employment to three men, the annual sale being calculated at 30,000 shaws. A preference is given to the wool of Tibet, and 24 pounds weight of the best of it is said to sell at Cashmere for 20 rupees. The wool is spun by women, and coloured afterwards. It appears also, from a book quoted in the 'Naturalist's Library' ('*Ruminantia*,' part 2, by Sir William Jardine), that a fine shawl, with a pattern all over it, takes nearly a year in making. The persons employed sit on a bench at the frame; sometimes four people at each, but if the shawl is a plain one, only two. The borders are marked with wooden needles, there being a separate needle for each colour, and the rough part of the shawl is uppermost while it is in progress of manufacture. A Tartar half breed, having been found to thrive well in a colder climate, has been introduced into France, not without success. The Cashmeres however which are brought from the kingdom of that name are the shawls in high request, and those who are curious in such articles should remember that there are in India several other goats besides the true Cashmere breed whose wool is employed for the same purpose.

The Jaal Goat, *Capra Jaela* (*Capra Nubiana*, Gray), is found in the mountains of Abyssinia, Upper Egypt, and Mount Sinai.



Jaal Goat, or Abyssinian Ibex (*Capra Nubiana*, Gray).

The Syrian Goat, with its excessively long ears, which is plentiful in the East, and, according to Pennant, supplies Aleppo with milk, is worthy of especial notice, as well as the Dwarf African, with its two hairy wattles under the chin, and the pretty little Whidaw Goat. Lieutenant-Colonel Sykes, in his 'Catalogue of the Mammalia,' obtained by him in Dukhun (Deccan), notices *Capra Hircus*, Linn.: Bukee, of the Mahrattas. The goats in Dukhun are gaunt, stand high on their legs, have the sides much compressed, and are covered with long shaggy hair, which in most is black. Ears nearly pendent. Irides ochrey-yellow or reddish-yellow. Tail always carried erect in movement.

Pennant states that the Domestic Goat (*Capra Hircus*), inhabits most parts of the world, either native or naturalised, and that it bears all extremes of weather, being found in Europe as high as Wardhuys in Norway, where they breed and run out the whole year; but in winter only have, during night, the shelter of hovels. In that season they feed on moss and the bark of fir-trees, and even on the logs cut for fuel. Pennant quotes Dr. Solander as authority to show that in Norway and West Bothnia their skins formed an article of commerce, and says that these animals thrive equally well in the hottest part of Africa and in India and its islands. It is not, he adds, a native of the New World, having been introduced there first by the discoverers of that continent. In Britain the Domestic Goat is become comparatively rare, and even in its strong hold, Wales, it is no longer plentiful. In South Wales a goat is seldom seen, but there are still some wild ones in Glamorganshire. Their flourishing condition in the Principality at one time may be imagined from the size of the horns of the Cambrian he-goat mentioned by Pennant; they were 3 feet 2 inches long, and measured 3 feet from tip to tip.

Few animals, when properly treated, are more useful to man; and though it never can answer to breed the goat in districts which will carry sheep, in rocky and woody countries it is invaluable. The manufactures from the hair have been alluded to. The pillow of goats' hair that supported the head of the image with which Michal deceived the messengers of Saul when he sought David's life (1 Sam. xix. 13-16) will occur to every one; and Pennant thinks that the variety which furnished it was the goat of Angora. In the days of wigs, the hair of the common Domestic Goats of this country was in high request, and the whitest were made of it. The best hair for this purpose was selected from that which grew on the haunches, where it is longest and thickest. In Pennant's time a good skin, well haired, was sold for a guinea, though a skin of bad hue, and so yellow as to baffle the barber's skill to bleach, did not fetch above eighteen pence or two shillings. Goats' hair is at present used in the manufacture of wigs for the dignitaries of the church, and the members of the bar and the bench. The skin, particularly that of the kid, is of high importance to the glove manufacturer; it is also said to take a dye better than most others. The horns are useful for knife-handles; and the suet, it is alleged, makes candles far superior in whitenes and goodness to those made from that of the sheep or the ox, and, according to Pennant, brings a much greater price in the market. The flesh of the kid is good. "The haunches of the goat," writes the author last quoted, "are frequently salted and dried, and supply all the uses of bacon; this by the natives is called Côch yr wden, or hung venison. The meat of a castrated goat of six or seven years old (which is called Hyfr) is reckoned the best; being generally very sweet and fat. This makes an excellent pasty, goes under the name of rock-venison, and is little inferior to that of the deer." The medical properties of goats' milk and whey have been highly extolled, and the cheese is much valued in some mountainous countries.

The odour of the Goat, strong at all times, becomes insufferably powerful in the rutting season (from the beginning of September to November), but this pungent scent is not supposed to be unwholesome; and horses are said to be refreshed by it, whence the animal is frequently to be seen about stables. The female brings forth from the latter end of February to the latter end of April, after a gestation of four months and a half, generally two but sometimes three and even four young. The activity with which these animals will securely bound from rock to rock, and the unshaken firmness with which they will fix themselves on the edge of the highest precipices, are wonderful. Pennant says that when two are yoked together, as was frequently practised, they will, as if by consent, take large and hazardous leaps, and yet so time their mutual efforts as rarely to miscarry in the attempt. Nicholas Hasselgren in his 'Swedish Pan' ('Amœn. Acad.') states that goats eat 449 plants and refuse 126. The same author states that though they will eat greedily and safely long-leaved water-hemlock, monkshood kills them. Their favourite food consists of the tops, tendrils, and flowers of mountain shrubs and of aromatic herbs; to this delicate diet was supposed to be owing the salubrity of the milk. The blood was supposed to have its healing properties also: that of a he-goat dried is mentioned by Pennant as a great recipe in some families for the pleurisy and inflammatory disorders, and is noticed in Dr. Mead's 'Monita Medica.' As an enemy to the vine it was sacrificed to Bacchus; and the subject is prettily touched in many epigrams and verses, both Greek and Latin. The elegant lines of Ovid beginning "Rode caper vitem" are familiar to scholars. In that dark and melancholy time when modern witchcraft was supposed to be rife, and when the very absurdity of the alleged facts seems to have sharpened the belief of the credulous, and increased their eagerness to shed innocent blood, the Goat figures not only as the conveyance on which the witches flew through the air to their diabolical festivals, but as the shape in which Satan himself often exhibited his person to his votaries.

There is no doubt that the Domestic Goat will breed with the Sheep. F. Cuvier states that the mule which is the result of the connection participates in the nature of its parents, and is fruitful, but reproduces with difficulty. "I have had," says this zoologist, "a similar female mule, which in its form inclined to the sheep, while it leant to the she-goat in its gait and in its hair (par ses formes tenoit du mouton, et de la chèvre par ses allures et ses poils); it did not couple till the third year with a goat, and was fruitful."

During a visit to Rhenish Germany in the autumn of 1837 Mr. Ogilby learned from Professor Crétzschmar, the well-know editor of the mammalogical part of Dr. Rüppell's first 'Atlas,' the success of an experiment which the professor had been carrying on for some years in the neighbourhood of Frankfort-on-the-Main, to ascertain the possibility of procuring a cross between the Cashmere Goat and the Saxon Merino Sheep. With this intention Professor Cretzschmar had two or three years ago procured a large Cashmere buck, which was put into a stable with twelve Merino ewes. For two seasons however his hopes were disappointed, and it was not till the season of 1836 that the desired union took place. During the spring of that year the sheep very freely took the buck, and produced fine healthy lambs, which were, when Mr. Ogilby obtained his information, rather better than a year old. They were kept in a large stable with a number of pure Merinos, which is the usual mode of treating these valuable animals in that part of Germany, where the land is all under the plough, and there are neither sheep nor grazing farms; and so closely did they resemble the pure Saxon breed, that it was impossible to perceive any difference in their external characters.

The species of the genera of *Capreæ* in the British Museum Catalogue are as follows:—

Hemitragus Jemlaicus, the Jhâral or Tehr. This animal inhabits the loftiest mountains of India.

Kemas Warryato, the Warryato or Jungle Kemas. It is a native of India, and has been called the Wild Sheep of Tennasserim.

Ægoceros Pyrenaica, the Pyrenean Tur. It is a native of the Pyrenees, and is regarded by some as a variety of the Ibex.

Æ. Caucasica, the Tur, or Zac. It inhabits the Caucasus, and is sometimes called the Caucasian Ibex.

Capra Ibex, the Ibex, or Stein-Boc. This animal is a native of the European Alps.

C. Sibirica, the Tek or Takija. It is a native of Siberia, and is frequently referred to the Ibex.

C. Himalayana, the Sakeen or Skyn. It is also called the Himalaya Ibex. Dr. Gray observes that this is not probably distinct from *Ibex* (*Capra*) *Sibirica*.

C. (?) *lævicornis*, the Smooth-Horned Ibex. It is probably a hybrid.

C. Nubiana, the Beden, or Jaela. It is an inhabitant of Egypt, Arabia, and Crete.

C. Valie, the Walie. A specimen is in the Frankfort Museum.

Hircus Ægagrus, the Goat.

Fossil remains of the Goat have been found at Walton in Essex. Professor Owen says, on this discovery:—"Whether the *Capra Ægagrus* (*Hircus Ægagrus*) or the *Capra Ibex* should be regarded as the stock of the domesticated goat of Europe has long been a question amongst naturalists; the weighty arguments which may be drawn from the character of the wild species which was contemporary with the *Bos primigenius* and *Bos longifrons* in England is shown by the present fossil to be in favour of *Capra Ægagrus*." (Owen, *British Fossil Mammals*.)

CAPRE'OLUS. [CERVIDÆ.]

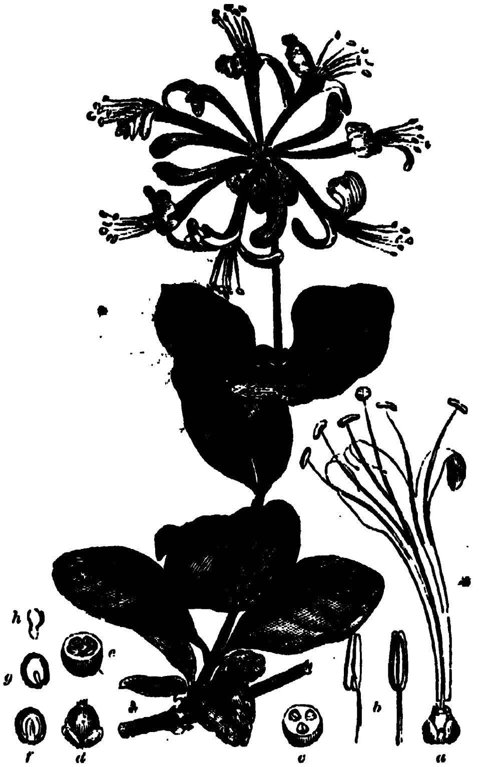
CAPRE'OLUS, an old name for the tendril of a vine.

CAPRICORNI. [AMMONITES.]

CAPRICORNIS. [ANTILOPEÆ.]

CAPRIFOLIA'CEÆ, *Caprifoils*, the Honeysuckle Tribe, a natural order of Monopetalous Dicotyledons, having an inferior ovary, opposite leaves without stipules, and a small embryo lying in a considerable mass of horny albumen. The type of the order is the genus *Caprifolium*, or Honeysuckle; the genera that are associated with it in part consist of dismemberments of *Lonicera*, and in part of plants having a resemblance to them in habit. The genera most dissimilar to *Caprifolium* are *Sambucus* and *Viburnum*; but their characters are more dependent for their dissimilitude upon the shortness of the tube of their corolla, and the manner in which the flowers are arranged, than upon any actual differences of organisation. *Caprifoliaceæ* differ from *Cinchonaceæ* in little except the want of stipules between the leaves, and consequently there is great resemblance in their sensible properties; their bark being often astringent, their leaves sometimes emetic, and the seeds of *Triosteum perfoliatum* similar to coffee.

The fragrance of the Honeysuckle is well known. The flowers of the Elder (*Sambucus nigra*) have a reputation as a medicinal agent. The plant dedicated to Linnæus, the *Linnæa borealis*, belongs to this order, and is said to possess diaphoretic and diuretic properties. The berries of *Loniceracærulea* are a favourite food of the Kamtchatkadales. Elderberry wine is a favourite beverage in some parts of England. The order has 14 genera and about 220 species.



Honeysuckle (*Caprifolium perfoliatum*).

a, Flower opened to show the insertion of the five stamens; *b*, front and back view of anthers; *c*, horizontal section of ovary; *d*, fruit; *e*, the same in section; *f*, seed; *g*, the same in section, showing the embryo; *h*, embryo.

CAPRIMULGUS, a genus of Birds belonging to the tribe *Insessores* and the family *Caprimulgidæ*. One of the species, *C. Europæus*, the Night-Jar, Night-Churn, or Fern-Owl, is a native of Great Britain. It is a nocturnal bird, hence its names. The species of *Caprimulgus* are also called Goat-Suckers. [GOAT-SUCKERS.]

CAPRISCUS, a genus of Fishes, to which some authors refer the European File-Fish. [BALISTES.]

CA'PROS, a genus of Acanthopterygious Fishes, belonging to the family *Scomberidæ*.

Only one species of this genus has yet been discovered; the *Capros aper* of Lacepède, and *Zeus aper* of Linnæus.

The characters of the genus are:—Body short, somewhat ovate, much compressed, and covered with small serrated scales; mouth capable of considerable protrusion. Dorsal fin emarginated (as in the dories), but no spines at the base, nor at the base of the anal fin.

Capros aper, the Boar-Fish, in general appearance is not unlike the dory (to which it is in fact closely allied), but, independent of other characters, may be distinguished by its mouth being more attenuated and protractile, the body being covered with scales, and the want of long filaments to the dorsal spines. This fish appears to be most generally about 6 inches in length, of a pale carmine colour above and silvery-white beneath. The colour of the upper part extends more or less down the sides of the body, and sometimes several orange-coloured bands are observable extending from the back downwards. The lateral line is not readily seen, excepting in recent specimens, when it is said to have a crystalline appearance. This fish is a native of the Mediterranean, and has been found on our own coast, but very rarely; a third specimen has recently been recorded as British. An interesting account of this fish will be found in Yarrell's 'History of British Fishes.'

CAPROVIS. [OVEÆ.]

CAPSELLA, a genus of plants belonging to the natural order *Cruciferæ*, the sub-order *Angustiseptæ*, the tribe *Lepidineæ*. It has a triangular-obcordate pouch; compressed valves, keeled but not winged; numerous seeds; simple filaments. The species of the Linnæan genus *Thlaspi*, without wings to their valves, form this genus. The best known is the common Shepherd's Purse (*C. Bursa Pastoris*). It is an annual herb, very variable in habit, a follower of man, and springs up wherever he fixes his abode. As a weed it is frequently very troublesome in gardens. It may be got rid of by hoeing in hot and dry weather whilst it is in flower, but if it be allowed to ripen its seed it is with difficulty eradicated. Koch describes several varieties of this plant. He also describes two other species as inhabitants of Germany. *C. procumbens* (*Lepidium procumbens* of Linnæus), and *C. pauciflora*, apparently a variety of the last. (Koch, *Flora Germanica;* Babington, *Manual of Brit. Bot.*)

CA'PSICUM, a genus of plants belonging to the natural order *Solanaceæ*. The species are called Bird-Peppers. The shell of the fruit is fleshy and coloured, and contains a pungent principle, which also exists in its seed in great activity. On this account both the fruit and seeds of different species of *Capsicum* are in request as a condiment, and either in the unprepared state or ground, when they are called Cayenne Pepper, form a conspicuous feature amongst the plants affording stimulating oils used by man. In Europe the *Capsicum* enters largely into the seasoning of food and the preparation of pickles, and in warmer countries it constitutes one of the first necessaries of life either green or ripe. The species from which the fresh Capsicums used in Europe are principally obtained is the *Capsicum annuum*, a weedy plant found wild in South America and the West Indies. This species grows from one to two feet high, forming a dark green bush, with ovate or ovate-lanceolate leaves; its flowers are small and white; its fruit is extremely variable in size, colour, position, and even in quality. Red and yellow are the prevailing colours; the oblong-conical is the ordinary figure; and to hang in a drooping position is the most usual direction of the fruit. But round, ovate, and even depressed fruit is known, and many varieties constantly bear their fruit in an erect position. Most of them are too pungent for European palates; but the large Red Bullock's Heart and Yellow Tomato Capsicums are mild enough to be sliced with salad.

A much hotter species is the *C. fruticosum*, or Goat-Pepper, a native of the East Indies, which differs from the *C. annuum* in being a shrub and in its fruit being very small. There is also a kind cultivated by the Chinese, with black fruit; and botanists recognise many others, but they appear to be in many cases mere varieties of *C. annuum* or *C. fruticosum*.

The acrid principle of *Capsicum* has been analysed by Braconnot ('Annales de Chimie,' vol. vi., p. 122), who found it not to be volatile, to dissolve readily in water, more freely in alcohol and ether, and that it is mixed with mucilage, wax, and resin.

The species of *Capsicum* are easily brought to perfection in this country. Their seeds are sown in a hot-bed in the beginning of April; the young plants are managed like other tender annuals; and about the end of May they are planted in the open air under a south wall. They will readily ripen their fruit in such a situation.

CAPSULE, a vague name given by botanists to any kind of dry seed-vessel containing many cells and seeds. It usually opens by valves.

CARA'BIDÆ, a family of Coleopterous Insects of the section *Pentamera* of Latreille. This family, named as above by M'Leay, is nearly identical with Latreille's section *Grandipalpi* as given in Cuvier's 'Règne Animal.' The distinguishing characters are:—Anterior tibiæ without emargination on the inner side; head narrower than the thorax; eyes rather prominent; palpi with the terminal joints often compressed, large, and somewhat triangular in shape; mandibles simple, moderately long, and rather thick.

The species of the *Carabidæ* are usually large, and adorned with brilliant metallic colours.

CA'RABUS, a genus of Coleopterous Insects, of the family *Carabidæ*. This must not be confounded with the genus *Carabus* of Linnæus, which according to many of the modern authors is divided into several families, and each of those families contains numerous genera. The necessity for sub-dividing the group called *Carabus* by Linnæus will be seen when it is taken into consideration that there are probably now about 800 species discovered.

The genera *Carabus*, *Tefflus*, *Procerus*, *Procrustes*, and *Calosoma*, contain the largest species of the Carnivorous Beetles, and together appear to form a natural group: we will therefore here notice the distinguishing characteristics of each, omitting those of *Calosoma*, which will be found under that head. These genera are usually arranged in succession as follows:—*Tefflus*, *Procerus*, *Procrustes*, *Carabus*, and *Calosoma;* and their chief technical characters may be readily seen by the following table:—

1. Anterior tarsi the same (or nearly so) in both sexes.

a. Labrum entire	*Tefflus.*
b. Labrum bilobate . . .	*Procerus.*

2. Anterior tarsi with the three or four basal joints dilated in the males.

a. Labrum trilobate	*Procrustes.*
b. Labrum bilobed	*Carabus.*

In *Tefflus*, *Procerus*, and *Carabus*, there is a simple tooth-like process in the emargination of the mentum; whilst in *Procrustes* this process is broad and slightly notched at the apex. The terminal joint of the palpi in these genera is nearly triangular, and larger in the males than in the females. In *Procerus* this joint is much larger in proportion than in either *Carabus* or *Procrustes;* and in *Tefflus* it is most developed, and is of an elongate form, slightly convex anteriorly. (*Fig.* 2.)

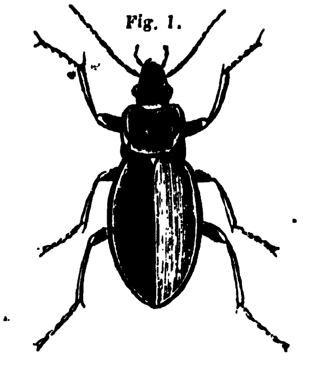
Tefflus Megerlei. The only species known of this genus is nearly two inches long, and is black; the thorax is almost double the width of the head, slightly convex and rugose, and has the lateral and posterior margins reflected; it is truncated anteriorly and posteriorly, and the lateral margins and posterior angles are rounded; the elytra are elongate-ovate, very convex, and furnished with seven smooth elevated longitudinal ridges, and in the space between these ridges there is a chain of small elevated tubercles; the legs and antennæ are moderately long. This rare and conspicuous insect is found in Senegal and on the coast of Guinea.

Procerus scabrosus is about two inches in length, and in the broadest part of the elytra about three-quarters of an inch in width, and of a bluish-black colour; the thorax is broad, truncated anteriorly and posteriorly, very slightly convex, and rugose; the elytra are oval, convex, and covered throughout with small tubercles. This is the largest of the carnivorous beetles known.

M. le Comte Dejean describes three other species belonging to this genus, which are all of a beautiful blue or violet colour above, and black beneath. The *Proceri* are often found under dried leaves in the forests and on the mountains of Russia, Hungary, and Asia Minor: they are the giants of European *Carabidæ*.

Four species of the genus *Procrustes* have been described, the largest of which, *P. coriaceus*, [illegible] recorded as British; it is however so rare in this country as to have given rise to doubts as to its being strictly an inhabitant. In France and Germany it is tolerably common, and is found in woods. *P. coriaceus* is rather more than an inch and a half in length, and of a dull black colour; the thorax is nearly smooth; the elytra are rugose, and of an ovate form.

Fig. 1.



Carabus violaceus.

Fig. 2. Fig. 3.

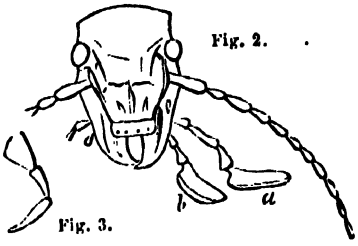


Fig. 2, Head of *Tefflus Megerlei*, magnified. *a*, maxillary palpus; *b*, labial palpus.
Fig. 3, maxillary palpus of *Carabus violaceus*.

Of the genus *Carabus* upwards of 120 species have been described, the greater portion of which inhabits Europe, Siberia, Asia Minor, and the northern parts of Africa.

From the immense number of species Count Dejean has found it necessary in his descriptions to arrange them under 16 divisions, founded principally on the sculpture of the elytra. Mr. Stephens, in his 'Illustrations of British Entomology,' describes 17 species: the most common are—*C. violaceus*, *C. monilis*, *C. catenulatus*, *C. hortensis*, *C. cancellatus*, and *C. arvensis*, all of which are tolerably abundant in the neighbourhood of London.

C. hortensis is very frequently met with on pathways (especially early in the morning), and not uncommonly with a worm in its jaws. It is about an inch long; the head and thorax are of a copper-like hue, and the elytra are brassy-green; the under parts of the body are black; the elytra are faintly sculptured, and exhibit three longitudinal rows of impressions, and numerous rows of very delicate confluent punctures.

C. violaceus is equally common with the last; it is dull black, and has the margin of the elytra of a copper-like hue; this tint is also more or less observable on the thorax; the elytra are very delicately punctured, and appear smooth to the naked eye, in which respect this species may be easily distinguished from *C. catenulatus*, which has the elytra distinctly sculptured. *C. catenulatus* also differs in form considerably from *C. violaceus*; it is dull black, and has the thorax and margins of the elytra of a purple or blue colour. Its locality is heaths and commons, where it is found under clods of turf, &c.

C. cancellatus appears to confine itself to old pollard-willows, at the roots and under the loose bark of which it is found in abundance. This species is about three-quarters of an inch long, and of a brassy hue above. The elytra are adorned with three distinct longitudinal rows of oblong elevated tubercles, and between these there is a smooth elevated stria.

(Dejean, *Species Générale des Coleoptères*.)

CARACHICHU, a name given in Brazil to the *Solanum nigrum*. It is also called Erva Moria. [Solanum.]

CARADOC FORMATION, the uppermost of the two great divisions of the Lower Silurian Strata of Murchison. It is not well and clearly seen except in Salop, the Abberley and Malvern Hills, Woolhope, May Hill, and other points on the eastern borders of Wales.

CARAGA'NA, a genus of Papilionaceous Yellow-Flowered Shrubs, formerly comprehended in *Robinia*. Several species are cultivated in gardens, but they are not much valued. They are exclusively found in Asiatic Russia, Tartary, and the north of India; one of them, the *Caragana Gerardiana*, is one of the plants called Tartarian Furze by travellers.

CARAMBOLA. [Averrhoa.]

CA'RANX, a genus of Acanthopterygious Fishes, and belonging to the family *Scomberidæ*. This genus is distinguished chiefly by the lateral line of the body being furnished with a series of scaly plates. These plates are horizontally keeled (especially on the posterior half of the body), and frequently terminate in a spine or an angular projection, the point of which is directed backwards. The remainder of the body is covered with small scales. There are two distinct dorsa fins; the last rays of the posterior one are sometimes but slightly connected by membrane, or separated into spurious fins. Some free spines are placed before the anal fin. The teeth are very minute.

Several species of this genus inhabit the seas of Europe, but we are aware of only one which has occurred off the British coast, the *Caranx tracturus*. This fish, well known by the name of the Scad or Horse-Mackerel, is frequently met with on various parts of the coasts both of England and Ireland, and at times occurs in such immense shoals that the whole sea as far as the eye can reach appears alive with them. The Scad is about the size of the mackerel, to which it comes near in affinity. The body is more even in width (that is, less tapering towards the head and tail), and is of a dusky olive-colour above, exhibiting in certain lights splendid hues of blue and green; the lower part of the body is silvery-white, with the exception of the throat, which is black; there [illegible] a black spot just above the pectoral fin. This species, like many others found on our own coasts, occurs also on those of the Mediterranean. In some of the species of the genus *Caranx* the scaly plates are observable only on the posterior half of the lateral line, and the [illegible]rior part is furnished with small scales.

C. punctatus of Cuvier has but a single spurious dorsal and anal fin, whilst the *C. Rotleri* (*Scomber Rotleri* of Bloch) has several. *Scomber dentex* (Bloch), and one or two other species now included in this genus, are remarkable for having a single range of teeth and the body of a more elevated form.

C. Carangus (*Scomber Carangus* of Bloch), a large species of this genus from the Antilles, weighing from 20lbs. to 25lbs., is of a silvery hue, and has a black spot on the operculum; the body is compressed, and of a somewhat ovate form; the head is obtusely terminated. This fish is good eating, whilst the Bastard Carangue (*C. Guaraterebra*), another which closely resembles it, but wants the black spot, is apt to prove poisonous.

CARANXO'MORUS, a genus of Acanthopterygious Fishes belonging to the family *Scomberidæ*.

CARAPA, a genus of plants belonging to the natural order *Meliaceæ*. *C. Touloucouna* yields the Tallicoonah or Kundar Oil, which has a reputation as an anthelmintic. It is said to be well suited for burning in lamps. The bark of the root of *C. obovata* is bitter and astringent. The bark of *C. Guianensis* is used as an anthelmintic and febrifuge. (Lindley, *Vegetable Kingdom*.)

CA'RAPUS, a genus of Fishes belonging to the Apodal Malacopterygians.

CARAWAY. [Carum.]

CARBO, a genus of Birds, of the order *Natatores* and the tribe *Pelecanidæ*, to which Temminck referred the Common Cormorant. It is now usually placed in the genus *Phalocrocorax*. [Phalocrocorax.]

CARBON is one of the elements which occurs pure in nature. In this state it is called *Diamond*, and forms one of the most precious gems. [Diamond.] It is also found in a tolerably pure condition in *Graphite* (*Plumbago* or *Black-Lead*). This substance contains from 90 to 96 per cent. of Carbon, with the rest iron. [Graphite.] Carbon enters largely into the composition of Amber [Amber], and also of mineral Caoutchouc and the various forms of Bitumen. [Bitumen.] It forms the distinguishing element of *Coal*. [Coal.]

CARBONIFEROUS SYSTEM, the great group of strata which includes nearly all the valuable coal yet discovered. It consists of—

D. The Coal Formation.
 c. The Millstone-Grit Group.

B. The Mountain Limestone Formation.
 a. The Limestone-Shale Group.

The portions marked *a*, *c*, are the least constant in range and character; the Limestone-Shale graduates in South Wales to Devonian Strata, and in Ireland constitutes the Yellow Sandstone series of the northern counties. (Griffith.) Most of the coal of Ireland belongs to the Millstone-Grit group. [Coal Formation; Mountain Limestone.]

CARBUNCLE. [Garnet.]

CARCHA'RIAS, a genus of Fishes of the Shark Tribe. [Squalidæ.]

CARDAMINE, a genus of plants belonging to the natural order *Cruciferæ*, the sub-order *Siliquosæ*, and the tribe *Arabideæ*. It has a compressed pod, flat nerveless valves, a capitate stigma, the seeds in a single row, with the funiculus simple and filiform. The species, which are numerous, are usually smooth herbs, with stalked, entire, lobed, or pinnately cut leaves, and racemes of white or red flowers.

C. pratensis, Cuckoo-Fower, Bitter-Cress, Common Ladies' Smock, has pinnate leaves, the leaflets of the lower leaves roundish, slightly angled, those of the upper leaf linear-lanceolate, entire; the petals three times longer than the calyx, spreading; the stamens half the length of the petals; stem terete. This plant has large lilac-coloured flowers, and is exceedingly abundant in some parts of the country. It has a bitter taste, hence its name Bitter-Cress. It is generally in blossom when the cuckoo returns to this country, and at that period covers the fields as though linen was bleaching: these circumstances explain its other common English names. Till recently it retained a place in the London and Dublin Pharmacopœias. At one time it had the reputation of being a diuretic and antispasmodic, and a drachm of the flowers was administered as a dose in hysteria, chorea, epilepsy, and other nervous affections. It is a native of Europe, Asia, and America, and is abundant throughout Great Britain.

Babington describes four other species of *Cardamine* as natives of Great Britain, *C. impatiens*, *C. sylvatica*, *C. hirsuta*, *C. amara*: with the exception of the last they are common plants. *C. bellidifolia* has been figured in the 'English Botany' as a British plant, but no station for it is known. The leaves of *C. hirsuta*, when ripe and laid upon the ground, put forth buds which produce a new plant. It is extensively propagated in this way in moist soils. It is said that other species have the same property. *C. impatiens* is so named from its pods when fully ripened expanding suddenly with force when touched, and throwing the seeds to a distance.

(Don, *Gard. Dict.*; Loudon, *Encyc. of Plants*; Babington, *Manual of British Botany.*)

CARDIOSPERMUM, a genus of plants belonging to the natural order *Sapindaceæ*. The root of one of the species, *C. Halicacabum*, is said to be diuretic, diaphoretic, and aperient. In the Moluccas the leaves are cooked and eaten.

CARDIUM, a genus of Bivalve *Mollusca* belonging to the Acephalous *Lamellibranchiata*. It is the type of the family *Cardiadæ*, and the species are known by the common name of Cockle. The shell is equivalve, more or less cordiform, oblong or transversely ovate, usually inflated, closed or gaping posteriorly, longitudinally ribbed or furrowed in radiating fashion from the prominent beaks, rarely smooth; ribs often scaly or spiny; margin almost always crenulated. Hinge composed of two oblique primary teeth in each valve and two remote lateral ones (in certain exotic forms, the teeth become partially or wholly obsolete). The ligament short, external, conspicuous; pallial impression simple. The animal is suborbicular, tumid, its mantle freely opening in front with plain or less frequently fringed edges, conspicuously fimbriated in the neighbourhood of the two very short slightly-separated siphons, the branchial one of which is always fringed at the orifice. Foot very large, cylindrical, geniculated. Branchial leaflets unequal, labial palps rather long and triangular. (Forbes and Hanley.)

The shells belonging to this genus are very widely distributed, and many of them are remarkable for the elegance of their form and colouring. The species are about 200 in number. "We find," say the authors of the 'History of British Mollusca,' "the great assemblage of Cockles in the Indian Ocean, a region where about a third of the species are congregated. Around this centre the number of specific forms diminishes, though found in every sea. They are most plentiful everywhere within the tropics, and diminish as we proceed northward and southward; but some of the forms most prolific in individuals and most gregarious in habit are present in cold climates, and make up by abundance for the absence of variety. Of these several are valuable articles of food; and it may be said of all the *Cardia* that they hold a high rank among *Mollusca*, both for nutritive qualities and excellence of flavour. The genus contains several remarkable abnormal forms; some of the most singular are to be found in the Caspian and other relics of the great Aralo-Caspian Sea—the demonstration of which mighty inland ocean is among the finest discoveries of Sir Roderick Murchison.

"The geological distribution of this interesting group corresponds in extent with the geographical. Even in Palæozoic Strata we find the fossilised remains of Mollusks closely allied if not belonging to *Cardium*. In the Secondary Rocks, even in their oldest members, well-marked forms of *Cardium* are not unfrequent, often singularly similating those of existing times. During the later part of the Secondary epoch and the beginning of the Tertiary a group of half-ribbed cockles seemed to have been developed at the expense of ordinary forms, and to have dwindled away as they came near our own epoch, when but two or three allies of them are found." (Vol. ii. p. 3, 4.)

Cockles inhabit all parts of the ocean. Some species are constantly met with between high and low water marks, and they have presented themselves from the deepest sea-beds. Each species has however a very definite range. They lie buried in sand or sandy mud, often occurring in prodigious quantities. According to the researches of Dr. W. B. Carpenter, the shell of the genus *Cardium* has a very definite elementary structure. Externally it presents a tubular structure, but internally there is little development of organic structure.

C. edule (Linnæus), the Common or Eatable Cockle, is known by the following characters:—It is neither triangular nor porcelain-white. It has radiating ribs, which are neither armed with spines nor tubercles. This bivalve assumes a variety of appearances, and the adult especially differs from the young. Forbes and Hanley include under this the following species of other writers:—*C. vulgare*, Da Costa; *C. crenulatum*, Lamarck; *C. pectinatum*, Lamarck; *C. arcuatum*, Reeve; *C. zonatum*, Brown; *C. obliquum*, Woodward; *C. rusticum*, Chemnitz; *C. glaucum*, Brugiere; *C. Lamarckii*, Reeve; *C. Belticum*, Reeve.

This species is met with in most parts of the British Islands, and is almost everywhere regarded as a pleasant article of diet. The ordinary run of examples are from four-fifths of an inch to one inch in length, but on the coast of Devon, and especially at Limpstone on the mouth of the Ex, where they are cultivated in beds, they attain a much greater size. It is a gregarious animal, inhabiting the sands at low water, especially where there are large tracts of sand in the neighbourhood of æstuaries.

The Common Cockle has a wide geographical range, extending southward to the Canary Isles. It is also found in the Caspian Sea. It occurs fossil in the Red Crag.

The other British species enumerated by Forbes and Hanley, are—*C. aculeatum*, *C. echinatum*, *C. rusticum*, *C. nodosum*, *C. fasciatum*, *C. pygmæum*, *C. Suecicum*, and *C. Norwegicum*. They regard *C. Grœnlandicum*, *C. serratum*, *C. medium*, and *C. muricatum*, as spurious in th British Fauna.

CARDOON, a name applied to the blanched leaflets and stems of *Cynara Cardunculus*. [CYNARA.]

CARDUELIS, a genus of Birds belonging to the tribe *Insessores*, division *Conirostres*, and the family *Fringillidæ*. It has a lengthened conical compressed beak; the point attenuated and acute; commissure slightly curved. The nostrils basal, lateral, covered by small incumbent plumes. Wings lengthened, pointed; the first, second, and third quills longest, and nearly equal. The tail moderate, slightly forked. Feet with the middle toe longer than the tarsus, which is equal to the hind toe; lateral toes short, of equal length; claws slender, curved, and acute.

There are two species of this genus indigenous in Great Britain, the Goldfinch and the Siskin.

C. elegans (*Fringilla Carduelis*), the Goldfinch, is a well-known bird. It has a gay plumage, lively habits, an agreeable form and song, and a disposition to become attached to those who feed it. In captivity they can be taught a variety of tricks, such as drawing up water for themselves to drink in a thimble bucket, or opening the lid of their seed-box. They may be often seen performing with canaries in the streets of London.

The Goldfinch builds a very neat nest, and lays four or five eggs of a pale bluish-white colour, with a few spots and lines of pale purple and brown. It is a very general inhabitant of the British Islands. It is also found in Sweden, and is abundant in Germany, France, Provence, Spain, and Italy. It is found also at Corfu, Sicily, Malta, and Crete.

The whole length of this bird is 5 inches. It has a whitish horn-colour beak, black at the tip; the circumference at the base of the beak crimson-red; cheeks and ear coverts white; top of the head black; nape of the neck white; the back and rump a dusky wood-brown; the carpal portion of the wing and the smaller wing-coverts black; the greater wing-coverts and the outer edge of the basal half of each primary brilliant gamboge-yellow; the remaining portion of the primaries black; under surface of the body dull white. (Yarrell.)

C. spinus (*Fringilla spinus*), the Siskin. [ABERDEVINE.]

CARDUUS. [THISTLE.]

CAREX, a genus of plants belonging to the natural order *Cyperaceæ*, and the tribe *Cariceæ*. The flowers are diclinous, arranged in imbricated spikes, each covered by a glume; the female flowers have a single urceolate persistent perigone, in which the nut is completely inclosed; one style with two or three stigmas; the male flowers have three stamens without a perianth. The species for the most part are inconspicuous and unattractive plants. They are however exceedingly numerous. Lindley, in Loudon's 'Encyclopædia of Plants,' describes 105 species, and this is probably not more than half that are now known. Babington describes 66 species as natives of Great Britain, being the largest number of species of any genus of phænogamous plants in this country. Koch, in the 'Flora Germanica,' describes 103 species as natives of Germany and Switzerland. Although so numerous, they serve directly few of the purposes of man or the higher animals. Their leaves are tough and hard, so that none of them are eaten by cattle except in cases of great necessity. They are for the most part inhabitants of wet and swampy grounds, in bogs, fens, and marshes, in the temperate and northern parts of the world. In the hop-grounds of Great Britain the leaves of some of the species are used for tying the bines of the hops to the poles. In Italy they are used for placing between the staves of wine-casks, are woven over Florence flasks, and occasionally employed for making chair-bottoms. The leaves of the *Carex sylvatica*, according to Linnæus, are combed and dressed, and used as a warm lining for gloves and shoes; and thus protected, the Laplanders seldom suffer from being frost-bitten.

C. arenaria has a place in some of the continental Pharmacopœias; its root-stock being a reputed diaphoretic and diuretic. It is used under the name of German Sarsaparilla, and is employed in cases of skin-disease, as well as in secondary syphilis.

The *C. hirta* and *C. disticha* are often substituted fraudulently or by mistake for it, but do not, according to Bischoff, possess such active properties. It is not known to the practitioners in medicine of this country.

C. arenaria grows on the sands of the sea-shore, and is one of the plants which, in conjunction with the *Elymus*, *Arundo*, and *Psamma*, binds the loose sands, and forms them into solid embankments. Although most of the species are devoid of striking beauty, some of them when in flower are much admired on account of the elegant drooping of their panicles of golden-coloured flowers. This is the case with *C. remota* and *C. Fraseri*. Unattractive as the mass of these plants are to the general observer, they have been carefully studied by botanists, and Willdenow, Goodenough, Wahlenberg, Sckuhr, Scopoli, Boott, Babington, and S. Gibson have done much to throw light upon this obscure genus. Their importance in nature however must not be estimated by their appearance or their utility to man. They frequently form the only vegetation of the swamp, and by their existence and decay they gradually form a soil, on which plants more immediately useful to man may be grown.

CARIACUS. [CERVIDÆ.]

ÇARIAMA, or SARIAMA, the name by which the *Palamedea cristata* of Gmelin, *Dicholophus cristatus* of Illiger, *Microdactylus* of Geoffroy, the Saria of the Guaranis of Paraguay, and the Seriema or Ceriema of the Brazilian natives, is known to the Portuguese colonists of Brazil.

Marcgrave, Piso, D'Azara, Geoffroy, and the Prince de Wied have entered into a detailed history of this bird, which has always attracted the notice of zoologists on account of the curious relations which its structure indicates to the *Grallatores* (Waders), the Gallinaceous birds, and even the *Struthionidæ*.

It is found in the great solitary mountain-plains, surrounded by the forests which extend over so large a proportion of Brazil, and where its sonorous voice often breaks the silence of the desert. It is also found in Paraguay, but is said to occur there more rarely. It feeds in a state of nature on lizards, insects, and molluscous animals, and not improbably small seeds occasionally.

The habits of the wild Çariama are of the most retired description. A tenant of the vast solitudes that form its wide spreading home, it flies from the face of man; and being almost always on the watch is very difficult of approach. Stalking slowly on the plain its eye instantly notes the distant intruder, and after a moment's hesitation it decides either to stay or fly, according to the circumstances. Those who have had the best opportunities of observing them in their native wilds state that the hunters, though surrounded by these birds, cannot without considerable labour obtain them. As soon as the bird perceives that it is pursued, it sets off with great rapidity; the pursuer follows on horseback, but it is not till after a sharp and tedious course, with all its turns and windings, that the Çariama, wearied out, either crouches on the ground, or alights on some bush or tree. Till this happens the horseman in vain seeks for an opportunity to throw his lasso or pull his trigger.

But wild as the bird is in its natural state it is easily domesticated, and will live sociably with the other tenants of the poultry-yard. In this state they will eat little pieces of meat, but are said to refuse maize, though it is probable that other kinds of grain may not be disagreeable to them. When thus tamed they will walk about the hamlet or village where they have been brought up, and even return after taking short trips in the fields like the poultry. The flesh is described as very good food; the Brazilians however do not hunt it for the game-bag.

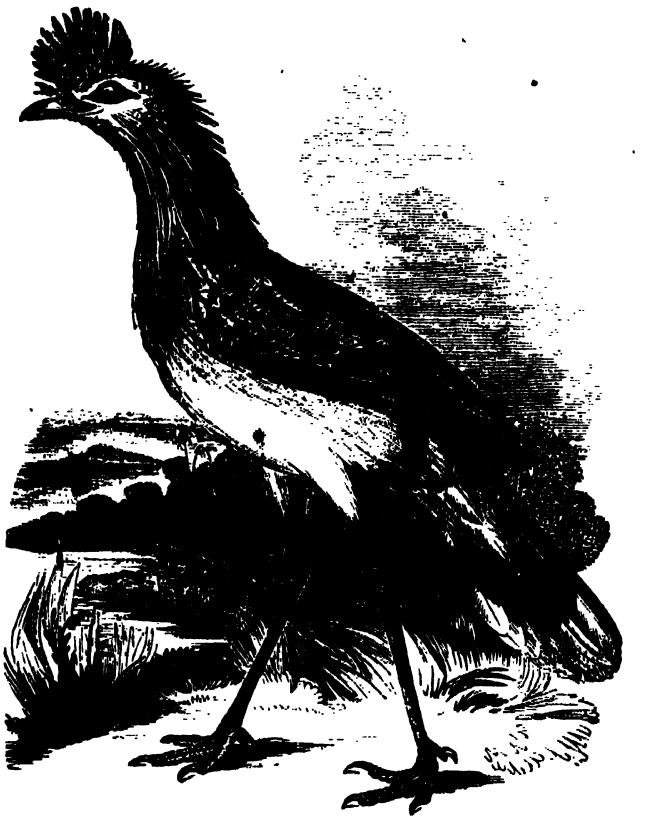
The nest is composed of dry sticks and branches, covered with cow-dung, and placed upon a low or a moderately high tree. The eggs are generally two in number and white.

It has the neck covered with long loose barbed feathers, floating and silky upon the nape, somewhat like those of the bittern: when the bird is excited or frightened it can raise them. A light crest consisting of a few disunited feathers forms an ornamental tuft on the front, and advances upon the base of the bill, which it overshadows, reminding the observer of the crests of the *Rupicolæ* (Cocks of the Rock) in its disposition. Space round the eyes naked, the nakedness, which is bluish, reaching to the bill. The upper eye-lid fringed with long dark eye-lashes. Feet long and slender, and the toes very short, whence Geoffroy's name. Tail rounded and of moderate length.

The general colour of the Çariama is an earthy-brown on the upper parts, while the lower parts are whitish. All the neck-feathers are finely rayed with zigzags of darker brown than that which forms the general ground-colour of the plumage. The two middle feathers of the tail are brown: the others for the most part black, with white extremities, and marbled with black upon a white ground at their insertion. The wing-feathers are blackish and traversed by white bands dotted with blackish. There are delicate zigzags of a clear brown on the feathers of the front of the neck, the ground colour of these feathers being whitish. The feathers of the breast and belly are longitudinally rayed with white in the direction of the shafts. The naked part of the leg, the feet, and the toes are of an orange-red. The bill, which is of a bright coral red in the adult, is blackish or marbled with black and reddish in the younger birds. The iris is yellow.

D'Azara gives 30 inches as the length of the young bird described by him; that of the Prince de Wied was half an inch more, and the adult male of the Museum of the Netherlands, from which Temminck's figure was taken, measures, according to him, 32 inches. The nestlings are covered with down, and with the iris of a very lively yellow. They are very soon able to run.

Temminck, after observing that the Çariama at first view seems to offer some resemblance to the Secretary-Bird of Africa (*Gypogeranus serpentarius*), remarks that this resemblance vanishes upon a closer inspection, and that, if it be permitted to form any judgment from the forms solely, it would seem probable that the skeleton of the Çariama, which was not known when he wrote, ought to have some relationship with that of the Common Bittern (*Botaurus stellaris*), of the Agami (*Psophia crepitans*), and the *Grallatores* generally. There is a skeleton of a female in the museum of the Zoological Society of London presented by the Earl of Derby, in whose possession the bird died. An account of the anatomy of this bird by Mr. Martin was published in the 'Proceedings of the Zoological Society.' In this paper Mr. Martin observes that "in its general aspect the skeleton of the Çariama is very remarkable. The comparative shortness of the neck, the compactness of the chest, and stoutness of the ribs, together with the abbreviated condition of the wings, appear as if out of harmony with the length of the limbs, especially of the tibia and tarsus, while the toes concluding this length of limb are short, the hinder one being situated high and not touching the ground.



Çariama (*Palamedea cristata*).

"Though the Çariama in its osseous structure exhibits but little resemblance to the birds of the Raptorial order, it approaches that order very remarkably in the structure of the eye, which is surrounded by a firm consolidated osseous ring. This ring departs materially in its formation from what obtains among the *Grallatores* generally, where it is imbricated and slight, and indeed scarcely merits the name of osseous."

For the anatomy of the bird, we refer the reader to Mr. Martin's paper, but we may observe that, according to Mr. Martin, "in the whole of the visceral arrangement a close affinity may be observed to the *Grus* tribe." In the Stanley Crane (*Anthropoides paradiseus*, Bechst.) the intestines are similarly disposed in folds or loops, and the two cæca, given off 6 inches from the anus, are 4 inches long. In the Stanley Crane however the muscular coat of the gizzard is thicker than in the Çariama, being in some parts an inch across, while in the latter bird it is about one-fourth of an inch; hence is there in this point an index of a less vegetable regimen. In the Stanley Crane the total length of the intestines is 5 feet 3 inches. In the Çariama it is 3 feet 5½ inches.

CA'RICA, a genus of plants belonging to the natural order *Papayaceæ*. One of the species, *C. Papaya*, is a remarkable tree found in various parts of South America, with a simple unbranched erect trunk, from 12 to 20 feet high, abounding in a milky juice, having broad 7-lobed leaves a foot at least long, and unisexual flowers, the males of which are monopetalous, with ten short stamens inserted in the mouth of the corolla; the females polypetalous, with a single ovary, having a starry sort of stigma. The fruit is thus described by Hooker in the 'Botanical Magazine:' "The corolla falls away, and the germen in coming to maturity becomes pendent; the tree, too, advancing in height casts its lower leaves from below the flowers, and the fruit constituting a large oblong kind of berry, or more correctly speaking pepo, rests suspended upon the leafless part of the trunk, much in the same way as that of the *Artocarpus*, or Bread-Fruit. The surface, when the fruit is ripe, is a pale and rather dingy orange-yellow, obscurely furrowed, and often rough with little elevated points. The flesh is very thick, coloured, but paler than the outside, and there passes through it longitudinally five bundles of vessels. In the centre is a considerable cavity, with five longitudinal ridges, and these are thickly clothed with numerous seeds." This fruit is called the Papaw, and is accounted of considerable interest in the tropical part of the world. An excellent history of its uses is compiled in the work already quoted, from which we borrow the following: "The papaw-tree is of rapid growth. St. Pierre probably spoke from his own knowledge when he described Virginia as having planted a seed which in three years' time produced a trunk 20 feet high, with its upper part loaded with ripe fruit. It is for the sake of this fruit mainly that the plant is cultivated; but if the flavour were not better than that yielded by what ripened in our stove, I cannot recommend it as at all agreeable." Brown, in his 'Natural History of Jamaica,' tells us that "it has a pleasant sweetish taste, and is much liked by many people; that while young it is commonly used for sauce; and when boiled and mixed with lime-juice and sugar is not unlike or much inferior to that made of real apples, for which it is commonly substituted." In the opinion of Sloane it is not a very pleasant fruit, even when helped with pepper and sugar; and the more ordinary use, he adds, of this fruit is before it is ripe, when, as large as one's fist, it is cut into slices, soaked in water till the milky juice is out, and then boiled and eaten as turnips or baked as apples. The juice of the pulp, according to Descourtilz, in the 'Flore Médicale des Antilles,' is used as a cosmetic to remove freckles on the skin caused by the sun; and the negroes in the French colonies employ the leaves to wash their linen, instead of soap. As a medicinal plant the Papaw-Tree is particularly deserving of notice. Hernandez long ago spoke of the milky juice of the unripe fruit as a powerful vermifuge, which has been confirmed by M. Charpentier Cossigni, as mentioned in the 'Asiatic Researches' by Dr. Fleming (vol. ii. p. 162). A single dose, that gentleman says, is sufficient to cure the disease however abundant the worms may be. Another French writer (Poupée Desportes) recommends the use of the seed instead of the juice. But the most extraordinary property of the Papaw-Tree is that which is related, first I believe by Brown, in his 'Natural History of Jamaica,' namely, that "water impregnated with the milky juice of this tree is thought to make all sorts of meat washed in it very tender; but eight or ten minutes steeping, it is said, will make it so soft that it will drop in pieces from the spit before it is well roasted or turn soon to rags in the boiling." Mr. Neill mentioned this circumstance more fully in his interesting 'Horticultural Tour through Holland and the Netherlands;' and it has repeatedly been confirmed to me by gentlemen of this country who have been long resident in the West Indies, and who speak of the employment of the juice for such a purpose as of quite a general occurrence; and more, that old hogs and old poultry which are fed upon the leaves and fruit, however tough the meat they afford might otherwise be, are thus rendered perfectly tender, and good too, if eaten as soon as killed; but that the flesh very soon passes into a state of putridity. The juice causes a separation of the muscular fibres. Nay, the very vapour of the tree serves the purpose; hence many people suspend the joints of meat, fowls, &c. in the upper part of the tree in order to prepare them for the table. Such is the effect upon hogs that feed upon the fruit, that the good housewives reject the flesh of such if it is destined for salting, well knowing that it is not sufficiently firm for that purpose.

"Whether this power of hastening the decay of meat be attributable to the animal matter or fibrine contained in the juice of the Papaw or not, I will not pretend to say; but the presence of such is a fact scarcely less wonderful than the property just alluded to. Two specimens of the juice were brought from the Isle of France; in the one it had been evaporated to dryness, and was in the state of an extract; in the other the juice was preserved by being mixed with an equal bulk of rum. Both were subjected to analysis by Vauquelin. The first was of a yellowish-white colour and semi-transparent. Its taste was sweetish. It had no smell, and was pretty solid; but attracted moisture when kept in a damp place. The second was reddish-brown, and had the smell and taste of boiled beef. When the first specimen was macerated in cold water the greatest part of it dissolved; the solution frothed with soap. The addition of nitric acid coagulated it, and rendered it white; and when boiled it threw down abundance of white flakes. When the juice of the Papaw is treated with water the greatest part dissolves; but there remains a substance insoluble, which has a greasy appearance. It softens in the air, and becomes viscid, brown, and semi-transparent. When thrown on burning coals it melted, let drops of grease exude, emitted the noise of meat roasting, and produced a smoke which had the odour of fat volatilised. It left behind it no residue. The substance was fibrine. The resemblance between the juice of the Papaw and animal meat is so close that one would be tempted to suspect some imposition, were not the evidence that it is really the juice of a tree quite unquestionable. This fibrine had been supposed previously to belong exclusively to the animal kingdom; but it has since been found in other vegetables, especially in *Fungi*."

C. digitata, the Chambum, is a Brazilian plant, and regarded with little less honour than the Upas-Tree itself. Pöppig says the juice which spirted on his face when he cut into the tree only caused itching in the face and a few blisters on the hands. The male flowers have a very disgusting smell.

CARINA, in Botany, the two oblique front petals of a Papilionaceous flower, united by their contiguous edges into an organ having a figure something like that of the keel of a boat.

CARINA'RIA, the name of a genus of *Mollusca*, arranged by Cuvier under his fifth order of Gasteropods (Lamarck's *Heteropoda*) as the type of that order, and by De Blainville under the first family (*Nectopoda*) of his order *Nucleobranchiata*. The shells of this genus were formerly known to collectors under the names of Venus's Slipper and the Glass Nautilus: indeed one of the species is the *Argonauta vitreus* of Gmelin.

The body of the animal is sub-cylindrical, elongated, transparent, dotted with elevated points, prolonged posteriorly, and furnished towards the upper part of its posterior extremity with a sort of fin, which performs the part of a rudder. A reddish thin compressed sub-circular fin, beautifully reticulated by decussating muscular fibres, furnished with a sort of acetabulum or sucker, rises from the belly nearly opposite to the point on the back occupied by the shell. With the aid of this fin it floats along. M. Verany says that, notwithstanding the greatest possible attention, he has not been able to discover the use of the sucker, or rather suctorial disc, in the ventral fin; but there can be little doubt that it is analogous to the foot in Gasteropods, and that the animal avails itself of its powers of adhesion by sticking to rocks or other submarine bodies, and thus lying at anchor, as it were, in repose, with the frail shell that protects the circulating and respiratory organs, together with the liver and generative gland, lowermost—the same position occupied by it when the animal is in motion.

The head is capable of contraction within the body, and is provided with a sort of retractile proboscis. There are two tentacula of some length and of a subconical shape, placed laterally at the insertion of the head; and there are two eyes situated at the base of the tentacula. The mouth is furnished with a circular jaw, armed with four rows of teeth, of which the two internal ones are fixed and small.

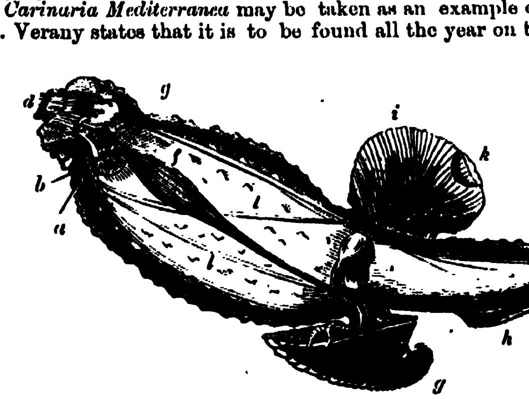
The organs of respiration, together with the heart and vent, are protected by a delicate transparent shell, somewhat compressed, without a spire, but with a summit a little recurved backwards, and the opening wide, entire, and oval. The vent is under the edge of the mantle, which envelopes the organs above mentioned and lines the shell.

The sexes, according to M. Verany, are separated as in the *Firolæ* (*Pterotrachea*); the sexual organ of the male being placed a little anteriorly on the right side under the subcircular belly-fin; that of the female is near the vent.

The digestive organs consist of a retractile tube furnished within with a horny rasp, and a short œsophagus, opening into a slightly dilated stomach, which is continued into an intestinal tube passing straight towards the shell, into which it enters, and making a convolution terminates in the vent.

There is between the eyes a ganglion from which many nerves are given off, and of these six are directed forwards and four backwards. Of the six directed forwards two go towards the mouth, and appear to provide for the action of the proboscis, two belong to the tentacula, and two to the eyes. Of the four directed backwards, two go directly to the nucleus in the shell, and the other two unite under the fin, whence they ramify into five branches, three of which are appropriated to the belly-fin, and two go towards the tail.

Carinaria Mediterranea may be taken as an example of the genus. M. Verany states that it is to be found all the year on the coasts (in the neighbourhood of Nice), but that it is sufficiently abundant in the months of May, June, and July. He further observes that it is rare to find it with the shell entire, that it feeds on gelatinous bodies and on very small fishes, such as *Atherina nana* (the Dwarf Atherine), and



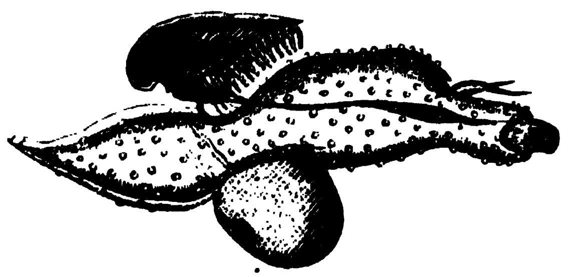
Carinaria Mediterranea, male.

a, Situation of the ganglion or brain; *b*, eye; *c*, head; *d*, retractile tube; *f*, digestive tube; *g*, shell containing the organs of respitation, heart, &c.; *h*, the posterior or rudder-fin; *i*, ventral-fin; *k*, the sucker; *l*, *l*, nerves. The figure, with slight modification, is taken from Verany's.

that he has often found in the stomach the remains of other *Carinariæ*, which satisfies him that the species is mutually destructive.

Delle Chiaje, who has placed the animal in its proper position with relation to the brain, has given a careful and detailed account of its organisation in his 'Memorie sulla Storia e Notomia degli Animali senza Vertebre del Regno di Napoli,' vol. ii. p. 214, illustrated in his plates 14 and 15. Delle Chiaje makes the spermatic canals rise at the posterior base or insertion of the ventral fin and proceed to the genital organ, near the origin of what we have termed the rudder-fin; but he gives no external view of the apparatus so conspicuous in M. Verany's figure.

Carinaria has never yet been taken in any other than warm latitudes. Three species, *C. vitrea*, *C. fragilis*, and *C. Mediterranea*, are recorded without reckoning Lamarck's *C. cymbium*.



The above is copied from the Iconographie of Cuvier's 'Animal Kingdom,' and represents the *Carinaria* with its back uppermost. It is denominated *Carinaria cymbium*, but there can be no doubt that it is *Carinaria Mediterranea.*

CARLINA. [THISTLE.]

CARNATION, a kind of Dianthus or Pink, a variety of the *Dianthus Caryophyllus* of botanists, much esteemed by florists for the beautiful colours of its sweet-scented double flowers. It is usually grown in rich light loamy soil, in which sand enough is mixed to prevent water stagnating, and is propagated either by cuttings or layering. A great many varieties are cultivated, the most esteemed of which are those with a strong tall stem about 3 feet high, and regularly formed flowers, with the stripes or markings clear, well defined, and broadest near the end of the petals. From their colours they are technically distinguished into Flakes, which have but one colour, disposed in stripes upon a white ground; Bizards, which have stripes of two colours; and Picotees or Piquettees, which have petals notched at the edges, and spotted instead of striped upon a ground that is most commonly pale-yellow.

CARNELIAN. [AGATE.]

CARNI'VORA, a term generally applicable to any creatures that feed on flesh or animal substances, but definitely applied to that order of the *Mammalia* which prey upon other animals.

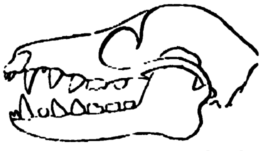
The forms of this order are varied, and the number of species considerable. Furnished like Man and the *Quadrumana* with three sorts of teeth, and nails or claws on the feet, they entirely differ from those two orders in never having the thumbs of the anterior extremity capable of being opposed to the other fingers. The greater or less development of their molar teeth as cutting or lacerating instruments seems to determine the kind of animal food fitted for their support. Those *Carnivora* which have their molars totally or partially tuberculated partake of a diet in which vegetables form a greater or less proportion, and those which have them serrated as it were with points live principally on insects. There are other modifications of these molars, fitting them for crushing bones or dividing animal muscle, according to the exigency of the animal; but in all, as a general rule, the articulation of the jaw does not permit of horizontal movement, the power being simply that of opening and shutting, upwards and downwards, like a pair of shears.

In their general organisation the prevailing feature of the skull is the great development of the zygomatic arch, affording room for the action of the powerful muscles that work the trenchant jaw; the orbit is not separated from the temporal fossa. The articulation of the bones of the fore-arm in most of the *Carnivora* is so constructed as to allow of free motion, though in a degree inferior to that bestowed on the *Quadrumana*. The brain (cerebrum) is considerable in bulk, well marked, but without a third lobe, and does not cover the cerebellum. Of all the senses that of smelling seems to be in the highest perfection; the pituitary membrane being extended over a manifold labyrinth of bony plates. The intestines are comparatively short, the nature of their food requiring less elaboration than that necessary for the extraction of nourishment from vegetables.

Cuvier gives the name of Carnassiers (Flesh-Eaters) to the order, and divides it into the following families:—

I. *Cheiroptera.*

These, as he observes, have still some affinities with the *Quadrumana*, as is manifested by the pendulous genital organ of the male, and the position of the teats of the female on the breast. Their distinguishing character consists of a fold of the skin, which rising at the side of the neck is extended between the fore feet and the fingers or toes, so as to suspend the animal in the air, and in those genera which have the bones of the hand sufficiently developed to spread a sufficient extent of this membranous skin, there is a power of executing all the evolutions required for flight. Strong calvicles and large shoulder-blades were required for this feat, and we accordingly find great strength and solidity thrown into those parts; but as the rotatory motion of the fore-arm would have been worse than useless, inasmuch as it would have weakened the force of the impulse of the membranous wing, and would have consequently lessened the power of flying, we find it almost entirely absent. Four great canine teeth are found in all the genera of this large family; but the number of their incisors varies. Some idea will be formed of the arrangement of the teeth in the *Cheiroptera* from the annexed cut.



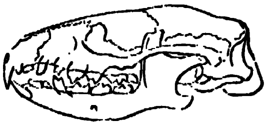
Skull of *Pteropus Keraudrenius.*

In the *Cheiroptera*, as we have seen, the teats are pectoral, but in all the rest of the families they are ventral.

The next family in Cuvier's arrangement is—

II. *Insectivora.*

The lateral membranes with which the *Cheiroptera* are furnished are no longer to be found in the *Insectivora*, which still have clavicles; and their molars like those of the first family are serrated with conical points. In their dental system the position and relative proportion of their incisors and canine teeth vary. Some have long incisors in front, followed by other incisors and canines lower than the molars, a scale of dentition to be found among some of the *Quadrumana* (*Tarsius*), and approaching in a degree the dental system of the *Rodentia*. Others have large and widely-separated canines, between which are small incisors, the most ordinary disposition of the teeth in the *Quadrumana* and *Carnivora*. The feet are short, and their motions comparatively feeble; the male organ is furnished with a sheath, and the teats are ventral. There is no cæcal appendage, and the entire sole of the foot is applied to the ground in walking. Their habits, resembling in a degree those of the *Cheiroptera*, are frequently nocturnal and subterranean. Insects form their principal nourishment, and many of them, especially in cold countries, pass the winter in a dormant state. Hitherto we have seen the carnivorous organisation in a comparatively mitigated state, but we now approach Cuvier's third family, the *Carnivora*, properly so called, which have every part of their frame, in the cats especially, formed for the destruction of other animals. In two of the tribes, but more particularly in one, namely, the *Plantigrades*, the carnivorous form is indeed somewhat modified; but among these three tribes we find the greatest harmony of parts, fitted for keeping down the numbers of the granivorous and phytophagous animals, to be anywhere observed among the *Mammalia*.



Skull of common Hedgehog (*Erinaceus Europæus*).

III. *Carnivora.*

In this family we have the thirst for blood at its highest degree of development, and with it the power and the instruments for gratifying the appetite. Four large, long, and distant canines, separated by the intervention of six incisors in each jaw (the root of the second of the lower incisors being a little deeper planted than the others)—molars, either formed entirely with cutting edges, or constructed partly with blunt tubercles; these, with the powerful mechanism of the jaw in which they are set, present a most formidable apparatus for finishing the bloody task which the rest of the frame of the *Carnivora* is so nicely adapted for commencing and continuing. The more completely trenchant these molars are, the more completely carnivorous are the habits of the animal, and the different gradations may be in general safely traced by observing the proportional extent of surface, considered with reference to its tubercular or cutting shape. The Bears, which, taken as a whole, may be said to be capable of supporting themselves entirely on vegetables, have nearly all their molar teeth tuberculated. [BEAR.]

The anterior molars have the most cutting edges, and then comes a molar larger than the rest, with a tuberculated heel or process more or less developed, and behind it one or two small teeth almost entirely flat. With these small teeth the dogs, as Baron Cuvier has observed, masticate the grass which they occasionally swallow for medicinal purposes: he also agrees with M. Frederic Cuvier in naming the great molar above and its antagonist below 'carnassières,' or flesh-cutters; the anterior pointed molars, false molars; and the posterior blunt molars, 'tuberculeuses,' or tuberculated molars.

By observing these differences of dental form, the genera of *Carnivora* are most surely established, and it may be laid down as a general rule, that those carnivorous animals which have the shortest jaw and the least development of the false molars are those in which the sanguinary propensity and the destructive power co-exist in the highest degree.

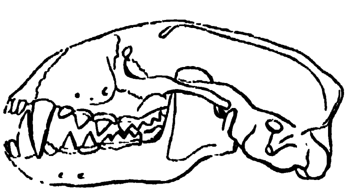
Many of the genera apply the whole sole of the foot (particularly of the hinder one) to the ground in walking, and this sole is generally destitute of hair. These are called *Plantigrada.*

Others again walk on the tips of the toes, as it were, and these, the *Digitigrada*, are endowed with great swiftness of foot. The clavicle in both is merely a bony rudiment suspended in the flesh.

Cuvier divides his *Carnivora* into the four following tribes :—

1. *Plantigrades.*

These possess a great facility, from the structure of the sole, of rearing themselves up on the hind feet. Cuvier observes that they participate in the comparative slow motion and nocturnal life of the *Insectivora*, and that they are like them deprived of a cæcum. The greater part of those whose geographical distribution is confined to cold countries pass the winter in a dormant state. They have all five toes on each foot. [Bear; Badger.] The annexed cut will serve as an example of the dental form and arrangement.



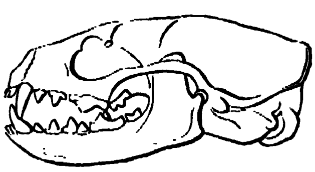
Skull of Common Badger (*Meles vulgaris.*)

2. *Digitigrades.*

This tribe is separated by Cuvier into two subdivisions :—

Subdivision *a*.

The animals composing this subdivision have been called Vermiform, from the comparatively great length and flexibility of their bodies and the shortness of their legs. Every one who has watched the serpentine movements of a ferret must have been struck with the great facility of motion given by this form, and its particular adaptation for passing through small openings and narrow burrows, and turning therein. Like the former families they have no cæcum, but unlike them they are not lethargic in winter. Though small they are of indomitable courage and ferocity, and literally most bloodthirsty, for the greater part of them live principally upon that fluid. The annexed cut will give an example of the general form of the skull and teeth.

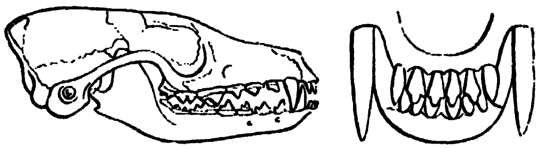


Skull of Polecat (*Putorius Zorilla*).

Subdivision *b*.

These have two flat tuberculated molars behind the upper great flesh-cutter, which has itself a sufficiently large heel or process. Many of these live upon carrion, and all have a small cæcum. [Canis.]

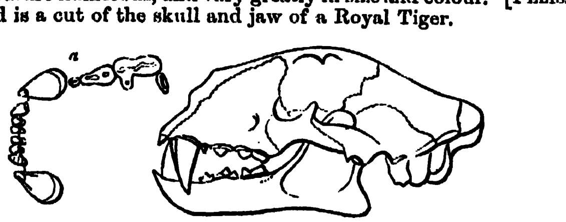
We refer to the next cut for a general idea of the dental system.



Skull of Common Fox (*Vulpes vulgaris*).

3. *Cats* (*Felidæ*).

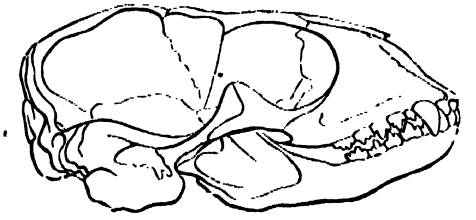
In this tribe we have the destructive power most highly developed. The short round muzzle, the abbreviated and powerful jaw, and the retractile claws sheathed by means of elastic ligaments when the animal is in a state of repose, so that they are kept sharp and ready for action, form with the rest of the organisation a destructive type of the highest order. All the Cats have two false molars above and two below; their upper flesh-cutter has three lobes and a blunt heel or process within; while the lower one has two pointed and cutting lobes, but without any heel or process; and they have but one small tuberculated molar above without any corresponding tooth below. The species are numerous, and vary greatly in size and colour. [Felis.] Subjoined is a cut of the skull and jaw of a Royal Tiger.



Skull of Royal Tiger (*Felis Tigris*). *a*, Teeth of upper jaw.

4. *Amphibia, or Amphibious Carnivora.*

Those who have seen a seal on the land will have noticed the comparative helplessness of the animal; for the short limbs enveloped in the skin only serve them by assisting their awkward shufflings when in that situation. But as they never come on the land excepting for the purposes of repose, basking in the sun, or suckling their young, their organisation is adapted to that element in which the great portion of their life is spent. The moment the Seal enters the water he is completely at his ease. Then the oar-like membranous hands and feet, or flippers, as some of our northern navigators not unaptly term them, the elongated body and moveable spine with its powerful muscular machinery, the narrow pelvis, and the close waterproof fur, afford, when taken together, a model for swimming. The annexed cut of the skull of a Common Seal will illustrate the general form and arrangement of the teeth. [Seals.]



Skull of Common Seal (*Calocephalus vitulinus*).

Fossil Carnivora.

Remains of the Mammiferous *Carnivora* are found abundantly in the Ossiferous caverns and Osseous Breccia. Those of a lion, a tiger [Felis], bears, a glutton, a weasel, a wolf [Canis], a fox, a dog, and hyænas, have been satisfactorily identified; but the bears, especially the great Cavern Bear (*Ursus Spelæus*) [Bear], and the hyænas [Hyæna] seem to have been predominant in many of the localities.

CAROB-TREE. [Ceratonia.]

CAROLINA PINK. [Spigelia.]

CARP. [Cyprinus.]

CARP-BREAM. [Bream.]

CARPEL, a term applied to the fruits of plants. If the fruit of a pæony is examined it will be found to consist of two or more hollow bodies terminated by a stigma, and containing vegetable eggs or ovules; taken collectively these are called a Pistil, but each separate body is a Carpel. A carpel is a transformed leaf, with its edges brought into contact, united, and generating ovules at the inside of the suture, while its midrib is lengthened and distended as a stigma. If several carpels are arranged in the centre of a flower, they have exactly the same respective position as the same number of leaves would have; and their sutures and stigmas are placed in the same position as the united edges and distended points of so many leaves would be placed. Supposing these carpels to grow together by their sides, their sutures will then be, with the ovules that belong to them, in the centre of the body formed by such a union. When fruits or pistils are composed of several carpellary leaves, or carpels not united, they are called Apocarpous. When the carpels grow together, the pistil or fruit is said to be Syncarpous. (Schleiden, *Principles of Scientific Botany.*)

CARPHOLITE, a Mineral, a variety of *Prehnite* [Prehnite], occurring in minute radiated stellate tufts, of a straw-yellow colour and silky lustre. It is brought from the tin-mines of Schlackenwald in Austria, with fluor-spar.

CARPHOSIDERITE, a yellow Phosphate of Iron, brought from Greenland. It occurs in reniform masses. (Dana, *Mineralogy.*)

CARPI'NUS, a genus of plants belonging to the natural order *Cupuliferæ*, and distinguished obviously from the Beech (*Betula*), the Oak (*Quercus*), &c., by its cupule being prolonged on one side into a leafy lobe, while its other lobes are shorter, and, as it were, abortive. *Ostrya*, the Hop Hornbeam, differs in having an inflated membranous cupule surrounding each nut. The following species are known :—

C. Betulus, Common Hornbeam. It is an indigenous British tree very common in copses, and frequently pollarded by the farmer. When allowed to acquire its natural appearance, it forms a graceful tree from 50 to 60 feet high, very often branching to within a short distance of the ground. In general appearance it resembles the Beech, but it does not acquire the smooth plump bole of that tree, nor are its leaves so shining. Its wood is coarse, and unfit for cabinet-makers' work, on account of the large size of its medullary processes; but it is tough, and well suited for cogs, handles of tools, and for other purposes in which strength is required. It is much consumed on the continent as fuel. Like the Beech, the Hornbeam, if stunted, retains its withered leaves all the winter; and as it bears clipping and close pruning remarkably well, it is much employed for hedges where winter shelter is required. The distinctive character of the Common Hornbeam is—leaves oblong, cordate, oblique at the base, doubly serrated, smooth, with the veins of the under side, which is very shining, downy at the axils. Lobes of the cupules nearly entire. A cut-leaved variety is known in gardens.

C. Americana, American Hornbeam. It has ovate oblong leaves, obliquely cordate at the base, doubly or almost simply serrated, smooth, with the veins of the under side downy at the axils. Lobes of the cupules somewhat falcate and serrated. Common from Lower Canada to the Carolinas, and extremely frequent in almost all soils except pine-barrens and swamps. It is a smaller tree than the European Hornbeam, not usually acquiring a greater height than 15 to 20 feet, although specimens have been found as much as 30 feet high. From the small size of this species it is little used by the Americans: its wood appears however to have the same properties as that of *C. Betulus.*

C. orientalis, Oriental Hornbeam. It has oblong doubly-serrated cordate leaves, and very little oblique at the base; when young, rather downy: lobes of the cupulet coarsely and unequally serrated. It is a bushy tree of small stature, found in the eastern parts of Europe and on the mountains of Caucasus. It is of no known use, and principally differs from the Common Hornbeam in its downy leafstalks and green much-lacerated cupules. It is the *C. duinensis* of Scopoli.

C. viminea is related to the last, but has taper-pointed leaves with simple or nearly simple serratures, and less deeply serrated lobes to the cupules. It is a large handsome tree with weeping branches, found on the mountains of Nepaul.

C. faginea, from the same country, is distinguished from the last by its woolly leafstalks and simply setaceo-serrated leaves, which are but little acuminated.

CARPOLOGY is a division of Botany comprehending what relates to the structure of seeds and their seed-vessels, or what is commonly called fruit. The subject is usually treated of incidentally in all elementary botanical works; and with much care by Mirbel in his 'Élémens de Botanique;' Lindley, in his 'Introduction to Botany;' and especially by Schleiden in his 'Principles of Scientific Botany.' [FRUIT.]

CARRAGEEN MOSS. [ALGÆ.]

CARRION-CROW. [CORVIDÆ.]

CARROT. [DAUCUS.]

CARR-SWALLOW, a name for the Black Tern (*Sterna fissipes*). [STERNA.]

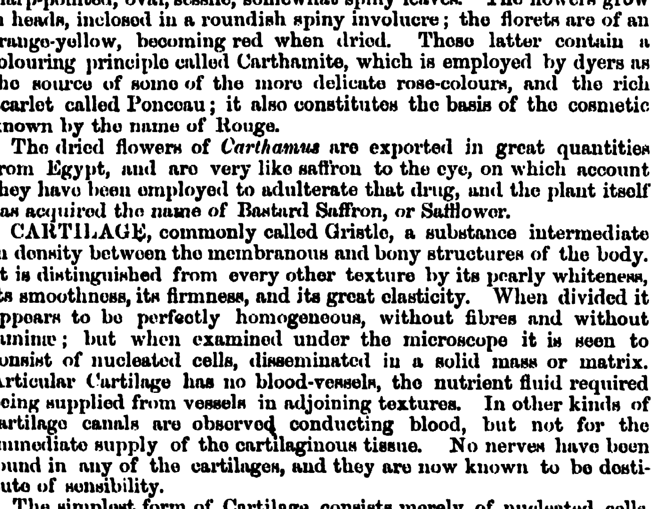
CARTER, a Cornish name for the Whiff, a fish belonging to the genus *Rhombus.* [RHOMBUS.]

CA'RTHAMUS, a genus of plants belonging to the natural order *Compositæ.* *C. tinctorius,* the Safflower, is a pretty annual plant, found wild in Egypt and the Levant. It has an erect cylindrical stem, branching near the summit, a foot or two high, and furnished with sharp-pointed, oval, sessile, somewhat spiny leaves. The flowers grow in heads, inclosed in a roundish spiny involucre; the florets are of an orange-yellow, becoming red when dried. These latter contain a colouring principle called Carthamite, which is employed by dyers as the source of some of the more delicate rose-colours, and the rich scarlet called Ponceau; it also constitutes the basis of the cosmetic known by the name of Rouge.

The dried flowers of *Carthamus* are exported in great quantities from Egypt, and are very like saffron to the eye, on which account they have been employed to adulterate that drug, and the plant itself has acquired the name of Bastard Saffron, or Safflower.

CARTILAGE, commonly called Gristle, a substance intermediate in density between the membranous and bony structures of the body. It is distinguished from every other texture by its pearly whiteness, its smoothness, its firmness, and its great elasticity. When divided it appears to be perfectly homogeneous, without fibres and without laminæ; but when examined under the microscope it is seen to consist of nucleated cells, disseminated in a solid mass or matrix. Articular Cartilage has no blood-vessels, the nutrient fluid required being supplied from vessels in adjoining textures. In other kinds of cartilage canals are observed conducting blood, but not for the immediate supply of the cartilaginous tissue. No nerves have been found in any of the cartilages, and they are now known to be destitute of sensibility.

The simplest form of Cartilage consists merely of nucleated cells, and closely resembles the cellular tissue of plants. This kind is found in the rudimentary spinal column of the early embryo; it also exists in the chorda dorsalis of the cartilaginous fishes. In other kinds of cartilage the cells are embedded in an intercellular substance, presenting certain varieties of appearance.



Articular Cartilage from the head of the humerus. Vertical sections.
A, section close to the surface; B, section far in the interior.

In Articular Cartilage the cells are oval or roundish, dispersed in groups through a nearly homogeneous intercellular substance. The cells measure from the 1300th to the 900th of an inch in diameter. In the interior part of the incrusting cartilages the cells usually assume a more or less linear arrangement. In the different cartilages the cells vary in size and form.

Ordinary permanent cartilage contains about three-fifths of its weight of water and becomes transparent when dried. It is resolved into chondrin by boiling. Cartilage contains a certain amount of mineral matters. Frommherz and Gugert obtained 3·4 per cent. of ashes. When analysed these ashes were found to consist of—

Carbonate of Soda	35·07
Sulphate of Soda	24·24
Chloride of Sodium	8·23
Phosphate of Soda	0·92
Sulphate of Potash	1·20
Carbonate of Lime	18·37
Phosphate of Lime	4·06
Phosphate of Magnesia	6·91
Oxide of Iron, and loss	1·00

The vital processes are carried on very slowly in cartilage. It is subject to absorption, and when thus removed by disease or when taken away by operation it is not again renewed. When fractured or broken the union is not effected by new cartilage, but by fibrous or areolar tissue, or bone.

Cartilage is not only closely allied to bone in the mechanical arrangement of its component fibres and in its chemical composition, but it sometimes supplies the place of bone, as in the fœtus and in young persons. Cartilages of this class, which regularly disappear as ossification advances, are called Temporary, in contradistinction to the Permanent, which remain during all periods of life. Permanent Cartilages either cover the extremities of the bones in the moveable joints or articulations, and are thence called Articular; or are attached to the extremities of the ribs, and are thence termed Costal. The Articular Cartilage consists of a layer of the same shape as the extremity of the bone which it covers, varying in thickness from one or two lines to the fraction of a line, and over its external or free surface there is always reflected a fine and delicate membrane, termed the synovial, which secretes the fluid by which the joint is lubricated and its free and easy motion secured, denominated synovia, or joint oil.

The Costal Cartilages, which are cartilaginous productions of the osseous ribs, are much larger and thicker than the Articular, assist in the formation of the thoracic cavity, and perform a very important part in the function of respiration.

The distinctive property of this peculiar form of organised matter, to which the name of Cartilage has been given, is elasticity, on which depends the specific use of this substance in the economy. It is mainly an adjunct to bones, counteracting certain evils which, but for the intervention of some substance of this kind, must necessarily have resulted from the hard unyielding nature of the osseous fibres. Covering the extremities of bones, or interposed between layers of bony fibres, without in the least diminishing the firmness and strength of the osseous fibres, it enables the bones to yield in the shocks to which the body is exposed in the ever-varying movements of the frame; defends them from fracture and displacement; and at the same time protects the great centres of the nervous system, the spinal cord and brain, from the concussions and jars to which these tender and delicate organs would, but for its interposition, have been constantly exposed.

(Quain's *Elements of Anatomy,* by Sharpey; Carpenter, *Principles of Physiology;* Simon, *Animal Chemistry;* Schwann, *On the Accordance in the Structure of Animals and Plants;* Kölliker, *Handbuch der Gewebelehre.*)

CARUM (from Caria in Asia Minor, where the plant was originally found), a genus of plants belonging to the natural order *Umbelliferæ,* to the sub-order *Orthospermeæ,* and to the tribe *Ammineæ.* It has an obsolete calyx, obcordate petals, with a narrow acute inflexed point, oblong fruit, carpels with five filiform ridges, interstices with single vittæ, a depressed stylopodium. The species are glabrous herbs, with perennial tuberous edible roots, pinnate leaves, and white flowers.

C. Carui, Common Caraway, has a fusiform root, bipinnate leaves, leaflets cut into linear segments, no partial involucre, the general involucre absent or of only one leaf. It is a native throughout the whole of Europe in meadows and pastures. It is found in Great Britain, but can only be regarded as a naturalised plant. The fruit of this plant is known in shops by the name of caraway seeds. [CARUM CARUI, in ARTS AND SC. DIV.] The leaves of this plant are frequently used in spring to put in soups, and the roots are boiled and eaten as parsnips, to which some persons prefer them.

Several varieties have been described by botanists. One of these is the American species *C. C. elongatum,* which has the segments of the leaves linear elongated.

C. verticillatum has the general and partial involucres of many leaves, the leaves pinnate, and the leaflets linear. The segments of the leaflets spread in such a way as to appear whorled; hence the trivial name. It is a native of the western parts of Europe. In Great Britain and Ireland it occurs as a rare plant in damp hilly pastures.

C. bulbocastanum of Koch, is the *Bunium bulbocastanum* of Linnæus. [BUNIUM.] It is the *Scandix* and *Sium bulbocastanum* of Sprengel and Moench. Babington, in his 'Manual,' has restored the Linnæan species. (Babington, *Manual of British Botany.*)

CARU'NCULA, a name applied by botanists to protuberances found occasionally surrounding the hilum of a seed. It is sometimes also called a Strophiloa. Parts of this kind occur on the seeds of *Euphorbia Lathyris.*

CA'RYA, a genus of plants belonging to the natural order *Juglandaceæ.* The species are North American trees, comprehending the various kinds of Hickory. This genus was formerly combined with *Juglans*, or the true Walnut; but it is distinguished by the shell of its nuts not being deeply furrowed, and by the catkins of the male flowers growing in threes. This must not be confounded with *Careya*, a genus of Indian *Myrtaceæ.*

Several species of Hickory are recognised by botanists; but, according to Michaux, the timber of all of them is so similar in quality that it is impossible to distinguish it. The bark of the Hickory is in all cases remarkable for the lozenge-shaped arrangement of its woody tissue. The wood is coarse-grained, very heavy, exceedingly tough and strong, and red at the heart; but on the other hand it decays quickly when exposed to the weather, and it is subject to be attacked by worms. It is on these accounts chiefly employed for the shafts and springs of carriages, for large screws, such as those of bookbinders' presses, for bows, chair-backs, whip-handles, wooden-cogged wheels, hoops for casks, and a variety of similar purposes. When burnt, hickory-wood consumes slowly, gives out a great heat, and forms a heavy coal, which remains glowing for a long while. It is considered to be upon the whole the best of all woods for fuel: it has however the fault of crackling and scattering about its sparks.

C. oliværformis, the Pecan or Pecana Nut (*Juglans angustifolia*, 'Hortus Kewensis'). This is a swamp species, with a slender stem, sometimes as much as 70 feet high. Its leaves are a foot to 18 inches long; their stalks are downy; the leaflets, which are 2 or 3 inches long, or as much as 5 inches on very strong shoots, are taper-pointed and firmly serrated. Their nuts are oblong, very smooth, angular in only a slight degree, about 1¼ inch long, and thinner shelled than the other sorts. The kernel is good to eat, and by far the best of the hickories; on this account the nuts are a small article of North American trade. The Pecan Nut is found in Upper Louisiana and New Orleans. It is common on the banks of rivers in Missouri, Illinois, and Arkansas. It does not occur, except in straggling specimens, more than 200 miles above the mouth of the Ohio.

C. sulcata (*Juglans laciniosa*, Michaux), Thick-Shell-Bark Hickory, Springfield or Gloucester Nut, is very common in all the low grounds, adjoining the Ohio and its tributaries, where, along with three-thorned gleditschias, black walnuts, Virginian bird-cherries, American elms, planes, and different species of *Acer*, it forms dense forests; it is seldom found west of the Alleghanies. Its trunk is as much as 80 feet high, on which it has a noble spreading head. Its bark, like that of some of the other hickories, strips off in ribands from 1 to 3 feet long, which separate at their extremities and curl backwards, finally adhering to the trunk only by their middle. The leaves vary in length from 8 to 20 inches; in form they are very like those of *C. alba*, but they usually have six or eight leaflets instead of four, which is the invariable number in that species. The nuts are oblong, sharp-pointed at each end, with four elevated angles, and a thick shell of a yellowish-brown colour, not white as in *C. alba.* They are brought to market in North America under some of the names mentioned above.

C. alba (*Juglans squamosa*, Michaux), White-Shell-Bark, Shag-Bark, Scaly-Bark Hickory. The shaggy appearance of the bark adverted to in speaking of the last species has caused the above names to be applied to this common species. It extends from South Carolina to the neighbourhood of Portland in the state of New Hampshire, where it is said to disappear. It is the most slender-stemmed of all the hickories, its trunk being sometimes 80 or 90 feet high and not more than 2 feet in diameter, and is described as a magnificent tree in its native forests. The young buds are woody, and slightly orange-coloured. The leaves are often 20 inches long; they have only four leaflets and an odd one, which are smooth and bright green above, finely downy on the under side, and serrated at the edge. The nuts are whitish, nearly round, hardly pointed at each end, angular, compressed, thick-shelled, remarkably small in proportion to the size of the fruit with its fleshy rind upon it. The kernel is next in quality to that of the Pecan Nut. They form a common article of market commerce.

C. tomentosa, Mocker-Nut Hickory, so called in consequence of the smallness of the kernel compared with the size of the nut. Its leaflets are from 7 to 9 in number, slightly round, very downy on the under side; they become bright-yellow in the autumn. The leaf-buds are thick, short, whitish-gray, and very hard in the winter season. The nuts are sessile, roundish, and inclosed in a rind which only opens half-way to let them drop out; they are light-brown, angular, and very little pointed. The bark of this species does not scale off, but rends into deep fissures. It grows the slowest of all the hickories, and is found chiefly in forests from New England to Virginia and in the Alleghanies; Pursh says in fertile soils, but Michaux adds that it nevertheless is the only hickory which makes its appearance in those sterile tracts called pine-barrens, where however it is only a scrubby bush. In the most favourable situations it rarely grows more than 60 feet high, and is usually a gnarled inelegant tree. Nuttall mentions a variety of this species as occurring a few miles from Philadelphia, with "fruit nearly twice the ordinary size, as large as an apple."

C. microcarpa. Leaflets about five, oblong-lanceolate, sharply serrate, and obviously tapered to the point; smooth on each side, glandular beneath. Fruit roundish, with a small thin-shelled nut, which is somewhat quadrangular and abruptly rounded at the end, with a very small point. According to Nuttall this is found wild on the banks of the Schuylkill, in the vicinity of Philadelphia, where it forms a large tree with an even bark. The fruit is much like that of *C. tomentosa*, and eatable, but very small, not exceeding the size of a nutmeg.

C. amara, Bitter Nut, or Swamp Hickory; found from the state of Vermont in the north, as far as the most southern parts of the American Union. In woods near New York, Michaux measured several individuals which were 10 or 12 feet in circumference, and from 70 to 80 feet high; but in general it is smaller. It is the latest in leafing of all the hickories. The leaflets are from 7 to 9 in number, smooth, coarsely and irregularly serrated, long, lanceolate, and more wrinkled than in other species. The fruit is small, roundish, with a thin rind; the nuts are obovate, depressed at the end, with a central projecting point; they have no angles, and are broader than they are long; the shell is thin and brittle, and the kernel so bitter and austere that even squirrels refuse to eat it. This species is easily known in winter by its yellow buds.

C. aquatica, found only in the lower parts of the southern states of the American Union, in swamps, and by the side of ditches surrounding rice-fields, along with red maples, deciduous cypresses, and Carolina poplars. It is readily known by its very narrow taper-pointed leaflets, which vary in number from 9 to 11. Its fruit is small, ovate, tuberculated, angular, and placed upon stalks in little clusters. The nuts are bright brown, ovate, angular, but little pointed at either end; they are very thin-shelled, and contain an extremely little kernel. The tree grows from 40 to 50 feet high, and is of much less value than the other species.

C. porcina, the Pig-Nut Hickory, or Hog-Nut. This is most common in the middle states, beginning with Lancaster County, Pennsylvania, in the north. It is one of the largest trees in the United States, growing to the height of 70 or 80 feet, with a diameter of 3 or 4 feet. Its brown shoots and oval very small buds distinguish it in winter. The leaflets are lanceolate, very taper-pointed, regularly serrated, and from 3 to 7 in number; they are quite smooth on each side, and on vigorous shoots in shady places their stalks are violet. The fruit is sessile, and varies in form from pyriform to spherical: its little nuts correspond in this respect with their rind; they are scarcely at all angular, and always rounded at the apex, with a sharp point; the shell is very thick and hard; the kernel sweet but small, and difficult to extract.

C. myristicæformis, Nutmeg Hickory. This is a little brown species, of which Michaux obtained a single branch with about 30 nuts at Charlestown from a negro gardener, who procured them in the neighbourhood of that city. Its leaves are like those of *C. aquatica*, but not quite so long and narrow. The fruit is sessile, oval, tuberculated, and contains a small smooth brown striated nut, with an exceedingly thick shell, and a very small kernel. Elliott, who resided near Charlestown, and wrote on the plants of Carolina, could never gain any further intelligence of this plant.

(Michaux, *Arbres Forestiers de l'Amérique Septentrionale.*)

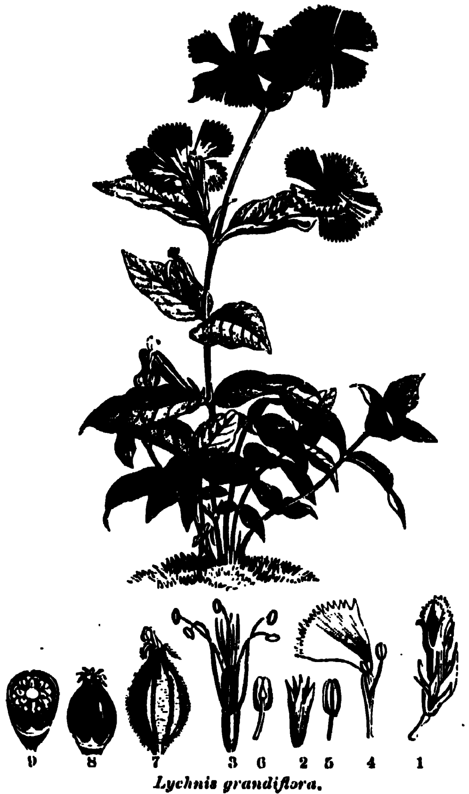
CARYO'CAR, the only genus of the natural order *Rhizobolaceæ*, one of whose species yields the Butter-Nuts of the London fruiterers' shops. One species is described by Aublet, under the name of *Pekea butyrosa*, as a large tree with a trunk 80 feet high, and 3 feet in diameter. The berries are covered by a rind two or three lines thick, and consisting internally of a buttery yellowish substance, which melts between the fingers, and which is sometimes used in cooking instead of animal butter. Under the rind lies a stone covered all over with slender stings, which easily separate, and become very troublesome to those who open the stones; within is a kidney-shaped kernel covered with a brownish membrane, and very good to eat; it is commonly served at table. It is called Pekea by the blacks in the neighbourhood of Oyapoco in French Guyana, where it is much cultivated. The species that furnishes the Butter-Nuts of the London markets is much like this, but is called Tata-youba by the natives of Guyana, and differs in having no stings upon the surface of the stone of its fruit: this is the *Pekea tuberculosa* of Aublet; the *Caryocar tomentosum* of modern botanists.

Another species, the *Caryocar nuciferum*, bears what are called the Suwarrow, or more properly Saouari, Nuts of commerce. It has only three leaflets to each leaf, each with a toothed margin and a taper-pointed extremity; the flowers are very large, deep brown externally and rich crimson in the inside; the fruit is in form like an egg, covered with a thick rough brown rind, beneath which is a soft greenish buttery substance. The nut has a stinging surface, and contains a very excellent kernel, from which may be extracted an oil like that from sweet almonds.

CARYOCATACTES. [NUCIFRAGA.]

CARYO'CRINITES, a genus of *Crinoidea*, from the Palæozoic Limestone of North America.

CARYOPHYLLA'CEÆ, *Cloveworts*, the Pink Tribe, a natural order of plants, the type of which may be considered the *Dianthus caryophyllus*, or Common Garden Pink. It consists of plants having narrow opposite undivided leaves, arising from tumours at the articulations of the stem; flowers with a definite number of hypogynous stamens; a fruit with a central placenta, and seeds that usually have the embryo rolled round mealy albumen. The species are in many cases mere weeds. In no instances have they properties of any importance, being mostly inert; but are occasionally objects of cultivation on account of their pretty flowers, as is the case in the whole genus *Dianthus*, and in several species of *Silene*, *Agrostemma*, *Lychnis*, and *Saponaria*. The order has always been divided into two parts, one of which has the sepals combined into a tube, and the other the sepals wholly distinct: Dr. Lindley at one time regarded these as distinct natural orders, the former constituting *Silenaceæ*, the latter *Alsinaceæ*. Of these the last-mentioned is very near *Illecebraceæ*, and formerly contained species that are now known to belong to that order. The other members of this family have relations with *Malvaceæ* and *Geraniaceæ*. The most important application of any of the species is the use of *Saponaria*, Soapwort, for washing. The order contains 43 genera and upwards of 1000 species. [LYCHNIS; SAPONARIA; SILENE; STELLARIA; SPERGULA.]



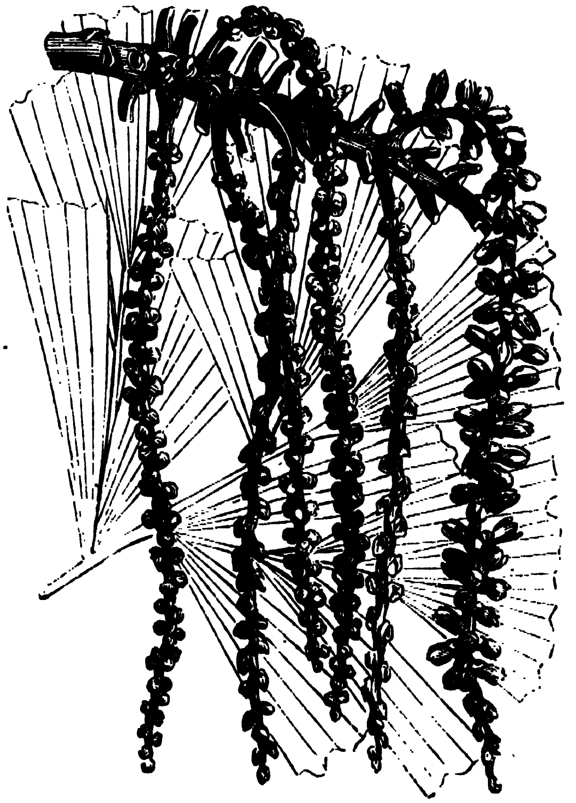
Lychnis grandiflora.

1, Unexpanded flower; 2, calyx; 3, pistil and stamens; 4, a petal, with stamen attached; 5, anther impregnated; 6, a back view of the same; 7, fruit, with calyx remaining after impregnation; 8, the same without the calyx, and as it opens when mature; 9, the same cut horizontally.

CARYO'PHYLLIA, a genus of Corals of the section *Madrephylliæa* of De Blainville. [MADREPHYLLIÆA.]

CARYO'TA, a genus of plants belonging to [illegible]e natural order of Palms. It has pinnated leaves and wedge-shaped leaflets, strongly toothed at the extremity; monœcious polyandrous flowers; a somewhat peltate stigma; and a 1- or 2-seeded pulpy fruit, with the embryo near the point of the albumen. The best known species, *Caryota urens*, is a native of most of the tropical parts of Asia, especially in mountainous situations, where, according to Roxburgh, it grows to be one of the largest of the Palm Tribe. Its trunk is described as being 60 feet high, thick in proportion, and slightly marked with annular scars, produced by the fall of its leaves. Its wood is so hard as to be cut with some difficulty, and is consequently of considerable value, provided the soft sap-wood in the centre is scraped away. Its leaves are pinnate, the leaflets obliquely triangular, the apex of the triangle being the point where they are attached to the stalk; their end is irregularly toothed, as if bitten or gnawed by an animal (technically præmorse); and their general appearance is on this account so remarkable that Rumf compares them not inaptly to the fin of a fish. The mass of flowers (spadix) is said to be from 6 to 16 feet long, divided into many simple branches, which are pretty thickly covered with innumerable sessile flowers. The fruit is called a berry, 1-celled, roundish, about the size of a plum, with a thin yellow rind, so acrid that it produces a severe sensation of burning if applied to the skin; and hence its name, *urens*. It is generally stated, apparently upon the authority of Rumf, that this noble species of palm yields no sap fit for manufacture into wine, and that the sago obtained from the soft central part of its stem is of such inferior quality as only to be employed in times of famine. Roxburgh how-

Caryota urens.



Caryota urens. A portion of the spadix.

ever gives a very different account of it. He says :—"This tree is highly valuable to the natives of the countries where it grows in plenty; it yields them during the hot season an immense quantity of toddy, or palm-wine. I have been informed that the best trees will yield at the rate of 100 pints in the 24 hours. The pith, or farinaceous part, of the trunk of old trees is said to be equal to the best sago; the natives make it into bread, and boil it into thick gruel. I have reason to believe this substance to be highly nutritious. I have eaten the gruel, and think it fully as palatable as that obtained from the Malay countries." This remarkable tree is not uncommon in this country in hot-houses where palms are cultivated.

CASCARILLA, an aromatic bark yielded by more than one species of *Croton*, a genus of plants belonging to the natural order *Euphorbiaceæ*. [CROTON.]

CASEARIA, one of the five genera of plants constituting the natural order *Samydaceæ*. Several of the species are used medicinally. The leaves of *C. ulmifolia* are astringent, and in the Brazils are applied to recent wounds. A decoction of the leaves of *C. lingua*, called by the Brazilians Cha de Frade and Lingua de Fin, is used in fevers and inflammatory disorders. *C. astringens* is used as an external application on account of its astringent properties. *C. Anavinga*, an Indian species, is bitter. The leaves of *C. esculenta* are eaten, but the root is bitter and purgative. (Lindley, *Vegetable Kingdom.*)

CASHEW-NUT. [ANACARDIACEÆ.]

CASSA'VA, or Manioc, a nutritious fecula obtained from the roots of *Jatropha* or *Janipha Manihot*, and some allied species. This plant belongs to the natural order *Euphorbiaceæ*, and abounds in a highly poisonous juice, which contains Hydrocyanic or Prussic Acid, so that very small doses produce the most dangerous consequences. The acid however is easily driven off by heat, and consequently there is no practical difficulty in procuring the nutritious substance in a pure state. In order to effect this the roots are peeled, well washed, and then ground between millstones till they are reduced to the state of paste. This is subjected to pressure for the purpose of depriving it as far as possible of the juice; the residue is placed in vessels over a brisk and regular fire, and continually stirred until it becomes dry; it then acquires a granular appearance, is gradually cooled, and afterwards packed in barrels, when it may be preserved for a great length of time. Half a pound of this substance daily is said to be sufficient to support a vigorous man. Tapioca is a preparation of Cassava, but contains less nutritive matter. Tapioca consists almost entirely of starch.

CA'SSIA (from the Greek κασσία), a genus of plants belonging to the natural order *Leguminosæ*. It consists of a large number of species, chiefly inhabiting the tropical or temperate parts of the world, and including among them the plants that produce the Senna leaves so commonly employed as a purgative. The genus *Cassia* belongs to the sub-order *Cæsalpinieæ* of *Leguminosæ*, and is characterised by De Candolle as follows :—Calyx consisting of five sepals which scarcely adhere at their base, but are more or less irregular. Petals five, unequal in size; stamens ten, distinct from each other; the three lowest being the longest, the four intermediate ones shorter and straight, and the three uppermost deformed; such of the anthers as are perfect open at the point; ovary stalked, usually curved; legume variable in form; the species consist of trees, shrubs, or mere herbs; the leaves are simply and abruptly pinnated, and usually bear glands on their stalks; the leaflets are opposite each other. Between 200 and 300 species are described by botanists.

C. acutifolia, a small under-shrub, with ovate lanceolate sharp-pointed leaflets, yellow flowers in terminal erect racemes, and compressed velvety legumes an inch long and half an inch broad. It is found wild in Egypt, Sennaar, and Abyssinia, and forms an important article in the commerce of those countries. It is chiefly sent to Alexandria for shipment, whence it has gained the name of Alexandrian Senna among the drug-merchants. It is considered the most valuable of all the sennas.

C. obovata, Aleppo Senna, has obovate very-blunt leaflets, and curved pods, with a very slight covering of down. The flowers are pale yellow. It is common in the same countries as the last, and mixed with it in commerce; it however chiefly constitutes the Aleppo Senna.

C. lanceolata. Leaflets very narrow and acute; pods plano-compressed, straightish, a little tumid in the middle. Found wild in Arabia, whence it is exported under the name of Senna of Mecca. It is a good deal cultivated in India, on which account, and from its being usually shipped for Europe from Indian ports, it has acquired the name of East Indian Senna in the market. As a species it appears to differ very little if at all from *C. acutifolia*.

Of the different species of *Cassia* mentioned above only the leaves are used in medicine. *C. Fistula* and other species are now referred to *Cathartocarpus*. [CATHARTOCARPUS.]

The leaflets of several different species of *Cassia* belonging to the section Senna constitute the various kinds of Senna called Senna leaves. In addition to the leaflets, the leaf-stalks and pods are frequently present, especially in the Alexandrian Senna, which contains also the leaves and pods of *Tephrosia Apollinea*, and the leaves, but rarely the follicles, of *Cynanchum Arghel*, Delile (*C. oleæfolium*, Nectoux), a plant belonging to the natural order *Apocynaceæ*, which possesses deleterious properties. The leaves of this last-named plant constitute two parts in ten of the Senna of Alexandria. The Tripoli Senna is free from it, as is likewise the Trinivelly Senna, which is now the best and cheapest in the markets of this country, and should always be preferred, as much of the griping tendency of common Senna is due to the presence of the Argel leaves. The Senna Leaves met with in the continental markets or shops are frequently adulterated with the leaves and berries of the *Coriaria myrtifolia*, a very poisonous plant.

When free from adulterations, Senna furnishes a most valuable purgative medicine; but when impure, its action is accompanied with nausea, griping, and other unpleasant symptoms. It is desirable therefore to free it from impurities before administering it or subjecting it to the action of water to form an infusion. [SENNA, in ARTS AND SC. DIV.]

CASSIA BUDS. The unexpanded flowers, when they have attained about a fourth of their complete size, of a species of *Cinnamomum*, are collected and sold under this name. Much diversity of opinion exists respecting the particular species of plant which yields this article. Professor C. G. Nees von Esenbeck (who is perhaps the best authority) says it is chiefly *C. aromaticum* (Nees), and partially *C. dulce* (Nees), *Laurus dulcis* (Roxb.), *Cinnamomum Chinense* (Blum.); while Dr. Th. Fr. Ludwig Nees von Esenbeck ascribes it to *Laurus Tamala* (Hamilton, 'Linn. Trans.' xiii. p. 556, the *L. Cassia*, 'Hort. Beng.'), and Dierbach to the *L. Cubeba* (Lour.), which last supposition is at variance with the statement of Loureiro ('Flora Cochinensis,' p. 310), respecting the action of the berries of that species.

Cassia Buds have the appearance of nails with heads of different sizes and shapes, according to the period of growth when collected. But an artificial process is employed by the Chinese collectors, of pressing the top against a flat hard body, by which the ovary or fruit is prevented falling out. Externally they are of a dark or grayish-brown; the fruit, which is within, is of a bright brown. The taste and odour resemble cinnamon. By distillation they yield a heavy yellowish-coloured oil. It was at one time supposed that an inferior sort, nearly devoid of taste, which is met with in commerce, was the genuine, which had been previously deprived of its oil; but Martius showed that this was a spurious kind, which is distinguished from the true by having the upper part of the calyx marked by six slits or incisions. It is moreover not so round as the true sort, and is furnished with a longer foot-stalk. It should be remembered that the term *Cassia* used here has no relation to the genus which yields the Sennas of commerce. [CASSIA.]

The uses of Cassia Buds are the same as those of cinnamon and cloves.

CA'SSICUS, a genus of Passerine Birds, of the family *Conirostres*, allied to the Beef-Eaters and Starlings. They are distinguished, among other characters, by their large, conical, and sharply pointed beaks. The species of *Cassicus* are all inhabitants of America. They are gregarious, and feed upon grain and insects.

CA'SSIDA, a genus of Coleopterous Insects of the family *Cassidiadæ*. It has the following characters :—Body generally somewhat oval or orbicular, and sometimes nearly square: thorax semicircular or forming the segment of a circle, the margins projecting considerably beyond and covering the head; the elytra also have the margins projecting, and forming as it were a kind of shield to the body; mandibles with several small notches; the anterior maxillary lobe as long as the inner one.

CASSIDI'ADÆ, Leach (*Cassidariæ*, Latreille), a family of Coleopterous Insects of the section *Cyclica* of Latreille. [CYCLICA.]

The species of this family are distinguished by their having the antennæ rather short, filiform or slightly thickened towards the apex, placed on the anterior part of the head, and almost close together. The legs are short and contractile; the tarsi are flattened, soft, and velvet-like beneath; the penultimate joint bilobed, the lobes completely inclosing the terminal joint; body generally very flat.

CASSOWARY. [STRUTHIONIDÆ.]

CASTA'NEA, a genus of plants belonging to the natural order *Corylaceæ*, one of th[illegible] species is the Sweet Chestnut. From the similarity in their name one would be disposed to believe that the genus to which Horse-Chestnuts belong was nearly related to this; they are however extremely different in everything except the unimportant circumstances of the fruit of both being prickly; and even in regard to this, their resemblance is more apparent than real, for the prickly part of the fruit of *Castanea* is an involucre, while that of the Horse-Chestnut is a pericarp; and the so-called seeds of *Castanea* are seed-vessels, while the parts which in the Horse-Chestnut correspond with these are really seeds. [ÆSCULUS.]

C. vesca (*C. vulgaris*, Lam.), the Sweet Chestnut, or Spanish Chestnut, is a deciduous tree of considerable size, with long shining serrated sharp-pointed leaves, clusters of long spikes of pale greenish-yellow unisexual minute flowers, having no corolla, and fruits consisting of a roundish prickly husk or involucre, technically called a cupula, and analogous to the cup of the acorn or the beard of the filbert, in which are contained one or more dark-brown ovate sharp-pointed nuts, each of which conceals a large single seed, and is tipped by the remains of several rigid styles. The seeds contain a large quantity of nutritive starchy matter, of a sweet flavour, on which account Chestnuts are extensively used as food in the countries where the tree abounds. In all Spain, the southern parts of France, Italy, and the adjacent countries, Sweet Chestnuts, either raw, or roasted, or ground into flour, or prepared in some other way, form a common article of diet. It is however not the wild *Castanea* which furnishes the nuts that are principally consumed in the south of Europe, and exclusively exported to more northern countries, but a number of cultivated varieties, the nuts of which are larger, and the seeds sweeter; of these the most remarkable are the Corive, the Ganiaude, the Egalade, and the Marron Cornu of the south of France. The Sweet Chestnut is a native of all the southern parts of Europe, extending eastward to the Caucasus, beyond which it hardly passes in Asia. In North America it occurs wild in great abundance in the hilly and mountainous parts of Virginia, the two Carolinas, and Georgia, as well as other districts, not however reaching beyond New Hampshire to the north. Michaux distinguishes the American from the European Chestnut as a peculiar species, but hardly upon sufficient grounds. It is always included as a wild plant in our English Floras, but upon no sort of authority. It is said indeed that its timber forms a considerable part of our oldest buildings, and that it has been ascertained to be the material out of which were constructed the ancient piles that have from time to time been taken from the Thames, the roof of Westminster Abbey, the church of St. Nicholas at Great Yarmouth, erected in the reign of William Rufus, and the timbers of other places; but these statements have arisen from the singular mistake of confounding the timber of *Quercus sessiliflora* with that of *Castanea vesca*; it is to the former that are to be referred all the supposed cases of ancient chestnut wood found in English buildings. [Quercus.] The Sweet Chestnut in its wild state acquires an unusual size. On Ætna, where it constitutes forests, there are trees of great antiquity, one of which, called the Hundred-Horse Chestnut, from its being able to contain a hundred mounted men in its hollow, has or had a circumference of above 160 feet; and in the department of the Cher, near Sancerre, there is still standing a tree of this species, which at 6 feet from the ground measures more than 30 feet in circumference, and is to all appearance still sound. It is stated that 600 years ago this was called the Great Chestnut-Tree, and its actual age is computed at 1000 years. The wood of the chestnut is well suited for paling or piles, as it resists well the influence of water; it is also used for mill-timber and for water-works, but it is not in this country of much importance.

Several varieties are cultivated in this country, among which are a shining-leaved, a variegated, and a cut-leaved sort; they are multiplied by grafting on the common Sweet Chestnut.

C. pumila, the Chinquapin-Nut, is a shrub rather than a tree, with leaves hoary on the underside, and small sweet nuts. It is a native of the United States of North America, especially in damp mountainous situations on a gravelly soil.

There are other species in India and on the west coast of North America.

CASTANOSPE'RMUM, a genus of plants belonging to the natural order *Leguminosæ*. The only known species of this genus is described as forming a tree from 30 to 40 feet high in the forests near Moreton Bay in Australia. It has unequally-pinnated leaves, with elliptical ovate acuminate entire smooth leaflets. The flowers are papilionaceous, and bright saffron-yellow. The pods are large, solitary, and pendulous, produced by the two-years'-old wood, obtuse, rather inflated, and containing from 3 to 5 large chestnut-like seeds. The shade afforded by the foliage is said to excel that of most Australian trees. By the natives the seeds are eaten on all occasions: they have when roasted the flavour of a Spanish chestnut, and travellers assert that Europeans who have subsisted upon them have experienced no other unpleasant effect than a slight pain in the bowels, and that only when the seeds are eaten raw. They are however hard, astringent, and not at all better than acorns. (Hooker, *Botanical Miscellany*.)

CA'STNIA, a genus of Lepidopterous Insects. [Sphingidæ.]

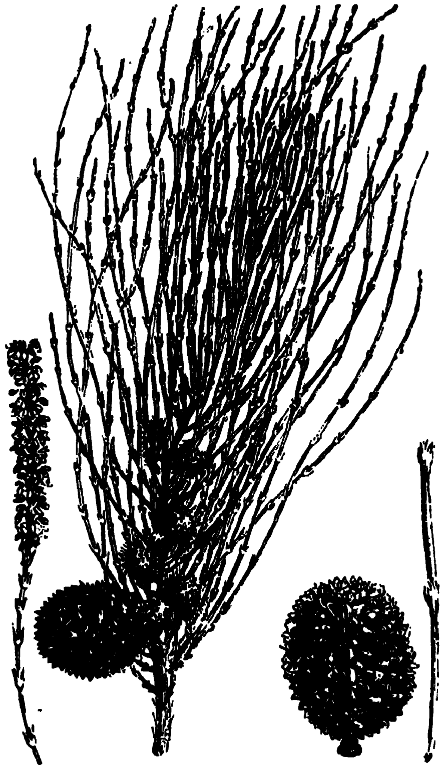
CASTOR. [Beaver.]

CASTOR, a colourless, transparent, feldspar-like mineral from Elba. Its hardness is 6·5 and specific gravity 2·38 to 2·4. It has the following composition:—

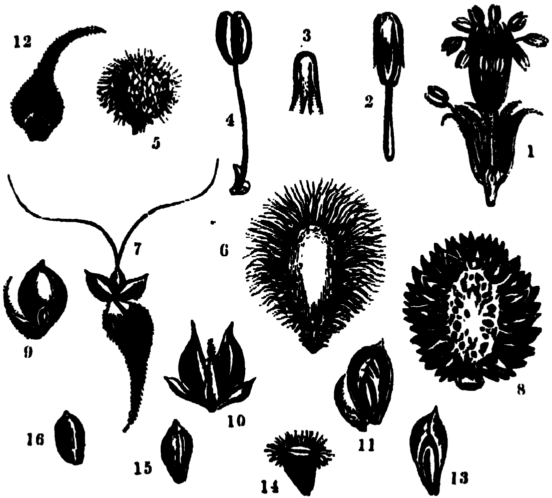
Silica	78·0
Alumina	18·9
Oxides of Iron and Manganese	1·6
Lithia, Potash, and Soda	2·8

CASTOREUM. [Beaver.]

CASUARINA'CEÆ, a natural order of Incomplete Exogens, whose branches are in all cases long, drooping, green, and wiry, with very small scale-like sheaths, in the room of leaves. The flowers are unisexual, and disposed in verticillate spikes; they have neither calyx nor corolla, are monandrous, and their ovaries are lenticular, with a solitary erect ovule. The fruit consists of hardened bracts, inclosing the small fruits, which are winged. This very small family, which is exclusively Asiatic, Australasian, and Polynesian, is allied to *Myricaceæ* and *Betulaceæ*. In habit and in their striated stems *Casuarinaceæ* are like the arborescent species of *Equisetum*. The timber of some species forms the Beef-Wood of the New South Wales colonists, and is of excellent quality. The young branches and cones of *Casuarina quadrivalvis*, the She-Oak, when chewed yield a pleasant acid. Cattle are said to be fond of them. The only genus is *Casuarina*, of which about 20 species have been described.



The She-Oak (*Casuarina quadrivalvis*).



1, Male flowers; 2, one of the same; 3, bracts; 4, male flower, without its bracts; 5, female flowers; 6, section of the same; 7, one of the same; 8, section of the cone; 9, capsule; 10, the same opened; 11, section of the same; 12, a bractea; 13, seed; 14, section of the same; 15, seed without an envelope; 16, embryo.

CAT. [Felidæ.]

CATABRO'SA, a genus of plants belonging to the natural order of Grasses, and to the tribe *Festucineæ* of that order. It has unequal very short glumes, rounded or truncate, without lateral ribs, much shorter than the spikelet; the flowers usually two, rounded on the back, distant; the outer palea membranous, with three ribs ending in teeth, which do not quite extend to the summit, and are connected by the scarious margin; the styles terminal; the upper glume has two very short faint lateral nerves, the awn absent. This is a genus formed by Paliset de Beauvois, and adopted by Babington in his 'Manual of British Botany.' The only British species is the *C. aquatica*; it has an equal panicle, with half-whorls of patent branches, and obtuse broadly linear leaves. It is found in ponds and ditches and wet sands. (Babington, *Manual of Brit. Bot.*)

CATALPA, a genus of plants belonging to the natural order *Bignoniaceæ*. It has a 2-parted calyx; campanulate corolla, with a ventricose tube, and an unequal 4-lobed limb; 5 stamens, two of which are fertile, the other three sterile; the stigma bilamellate;

the capsule silique-formed, long, cylindrical, 2-valved; the dissepiment opposite the valves; the seeds membranous at the margin, with pappus at the base and apex. The species are trees with simple leaves, opposite or disposed three in a whorl; the flowers terminal, panicled.

C. syringæfolia has flat cordate leaves, three in a whorl. This plant is a native of North America, and is found on the banks of the Ohio, Mississippi, and Delaware, also in the forests on the Wabash in Illinois, where it occurs in so great abundance that the wood is cut up for palings. It is a low-spreading singular-looking tree, with succulent shoots, easily injured by the frost. The leaves are large and come out late; the petals are white, spotted with purple and yellow. It is a plant well adapted for large shrubberies. There is one in the gardens of Gray's Inn, which is said to have been planted by Lord Bacon. The name of the genus appears to have been derived from the plant growing on the banks of the Catawba River. It does not bear fruit in this country.

C. longissima has oblong or ovate-lanceolate leaves, acuminated, three in a whorl, undulated. It is a tree 30 or 40 feet in height. It contains much tannin in its bark. It is known in the West Indies, by the name of French Oak, and the French call it Chêne Noir.

There are several other species of *Catalpa*, all elegant plants. The *C. syringæfolia* thrives well in common garden soil, and may be propagated by seeds or divisions of the root. The other species grow well in a mixture of loam, peat, and sand, or any light rich soil. Cuttings half-ripened root readily if planted in sand with a hand-glass over them.

CATAPHRACTUS, a genus of Fishes to which some Icthyologists refer the Armed Bull-Head. [Aspidophorus.]

CATA'STOMUS, a genus of Fishes belonging to the Abdominal *Malacopterygii* and family *Cyprinidæ*. The fishes of this genus are peculiar to the rivers of North America, and the species may be distinguished from others of the Carp section by their having the lips thick and pendent, and crenated or fringed at the edges; the dorsal fin short, as in the genus *Leuciscus* (which contains the Roach, Dace, &c.), and opposite to and above the ventral fins. M. Lesueur describes 17 species of this genus in the 'Journal of the Academy of Natural Sciences of Philadelphia.'

CATCHFLY, a name applied to several plants which have the property of retaining insects, either by their viscid surface or by some other means. In *Apocynum androsæmifolium*, and some others, they are caught in the hairs that clothe the mouth of the corolla; in *Silene* by the glutinous substance that exudes from the calyx; in *Dionæa* by the collapsing of the two sides of the irritable-toothed leaves. [Silene; Dionæa; Lychnis.]

CATECHU, an extractive matter containing large quantities of tannin, obtained from species of *Acacia*. [Acacia.]

CATENI'PORA, a genus of Corals found only in the Palæozoic Strata, and in Britain only in Silurian Rocks. [Madrephylliæa.]

CATERPILLAR, a name given to the larva state of Butterflies and Moths. [Larva.]

CAT-FISH. [Anarrhicas.]

CATHA, a genus of plants belonging to the natural order *Celastraceæ*. *C. edulis* is the Kat or Khât of the Arabs. "It would appear," says Dr. Lindley, "to be of a stimulating character. According to Forskühl the Arabs eat the green leaves with greediness, believing them to have the power of causing extreme watchfulness, so that a man may stand sentry all night long without drowsiness. They also regard it as an antidote to the plague, and assert that a person wearing a twig of it in his bosom may go among the infected with impunity; they even believe that the plague cannot appear in places where the tree is cultivated." ('Vegetable Kingdom,' p. 587.) At the same time Forskühl adds, "The taste of the leaves does not seem to indicate such virtues."

CATHARTOCARPUS (from καθαίρω, to purge, and κάρπος, fruit), a genus of plants belonging to the natural order *Leguminosæ*. It has very blunt sepals, hardly joined at the base, more or less unequal; 5 unequal petals; 10 unequal free stamens, the three lower ones longest, the four middle ones short and straight, the three upper ones bearing abortive difformed anthers; the anthers ovate, opening by two chinks at the apex; the ovary stipitate; the legumes terete or a little compressed, indehiscent, woody with elevated sutures, transversely many-celled inside, the cells 1-seeded and filled with pulp; the seeds elliptic, rather compressed, horizontal. The species are trees with abruptly-pinnate leaves and racemes of large yellow flowers. In appearance they are not unlike the Common Laburnum when in flower. This genus of plants was formerly comprehended under *Cassia* [Cassia], but was separated by Persoon, who has been followed by Lindley, Nees von Esenbeck, and others. The habit of these trees and the character of their fruit differ from the species of *Cassia*. It is also undoubtedly desirable that a genus like *Cassia*, with nearly 200 species, should be subdivided.

C. Fistula, the Purging Cassia, or Pudding Pipe-Tree, has leaves with 4-6 pairs of ovate rather acuminated glabrous leaflets; the petioles glandless; the racemes loose, bractless; the legumes cylindrical, rather obtuse, smooth. It is supposed to have been originally a native of tropical Africa, but is now extensively diffused over the globe, and is found abundantly in Hindustan, China, the East Indian Islands, the West Indies, and South America. It is a tree from 30 to 40 feet high, with yellow flowers and long cylindrical black pods, from 9 inches to 2 feet in length. The valves of this pod are thin, hard, and brittle; and its cavity is divided by numerous thin brittle transverse dissepiments; the partitions thus formed have each a single hard flattened ovate seed, surrounded by a soft pulp. The pulp has a sweetish flat not unpleasant taste, and is separated by boiling the pod in water, straining the fluid, and then evaporating it to the consistence of a thick extract. This extract acts as a mild purgative on the system, and was long in great repute in Europe on that account. It is now however seldom used; and although admitted into the lists of Materia Medica of the British Pharmacopœias, is only placed there as entering into the composition of the Electuarium Cassiæ and the Confectio Sennæ. The pulp, according to Henry, consists of 61 per cent. of sugar, 6·75 of gum, and 13·25 of tannin. It probably also contains Cathartine or an analogous principle.

C. Javanicus, Horse-Cassia, has leaves with 12-15 pairs of ovate obtuse glabrous leaflets; glandless petioles; axillary racemes; nearly cylindrical, very long, and transversely torose legumes. It is a native of Java and the Moluccas. Its legumes are above two feet in length, and contain a black cathartic pulp, which is used as a horse-medicine in the East Indies. G. Don has described a species of *Cathartocarpus* (*C. conspicuus*), which is a native of Sierra-Leone, where the pods are called Monkey Drum-Sticks.

(Christison, *Dispensatory*; Don, *Gardener's Dictionary*.)

CATILLUS, a fossil genus of Bivalve Shells, allied to *Crenatula* and *Perna*, so named by Cuvier and Brongniart. In the Chalk occur species of large size, remarkable for their largely fibrous texture. They have also been called from this circumstance *Inoceramus* by Sowerby, who includes in the genus one species from the Lias and others from the Gault.

CATKIN, in Botany, a kind of inflorescence which differs from the spike in nothing but its falling off the stem by an articulation, after its temporary office as the support of the organs of reproduction is accomplished. It occurs in the willow, the poplar, the birch, &c., which hence are sometimes called Amentaceous plants, *amentum* being the Latin name of the catkin.

CATLINITE, a form of argillaceous mineral called Pipestone by the North American Indians. It comes from the Coteau des Prairies, and is a red claystone or compacted clay. A similar material is now accumulating on the north shore of Lake Superior, at Nepigon Bay. Another variety is used by the Indians of the north-west coast of America. (Dana, *Mineralogy*.)

CAT-MINT. [Nepeta.]

CATOBLEPAS. [Antilopeæ.]

CAT'S-EYE, a form of Chalcedony, of a greenish-gray colour, having a peculiar opalescence, or glaring internal reflections, like the eye of a cat: the effect is owing to filaments of asbestos. It comes from Ceylon and Malabar, and possesses considerable value as a gem. (Dana, *Mineralogy*.)

CAT'S-TAIL GRASS, the common name of *Phleum pratense*, an agricultural plant, also called Timothy Grass. [Phleum.]

CAU'CALIS, a genus of plants belonging to the natural order *Umbelliferæ*, the sub-order *Campylospermeæ*, and the tribe *Caucalineæ*. It has a calyx of five teeth, the petals obcordate, with an inflexed point, outer ones radiant and bifid, the point slightly laterally compressed, the carpels with filiform bristly primary and more or less prominent secondary ridges, all bearing 1-3 rows of prickles. The species are herbs, with multiplied leaves and white flowers. They are called by the common name of Bur-Parsley. Two of the species are found in England, *C. daucoides* and *C. latifolia*. They are found in corn-fields on chalky soils; the last is a rare plant, and has been probably introduced. (Babington, *Manual of British Botany*.)

CAUDISONA. [Viperidæ.]

CAULERPITES, a group of Fossil Fucoid Plants, of which many species occur scattered through nearly all the marine formations. In the Oolites seven species have been found. The recent genus *Caulerpa* is found in warm southern climates.

CAULIFLOWER. [Brassica.]

CAULINIA, a genus of aquatic plants, belonging to the natural order *Naiadaceæ*. One of the species, *C. fragilis*, exhibits a circulation in its transparent joints, and was one of the first plants in which this phenomenon was noticed by Amici, and also probably by Costa.

CAVIA. [Cavy.]

CAVY is the vulgar name applied to various species of animals belonging to the genus *Cavia*. Of these the most common is *C. Aperea*, the Restless Cavy, or Guinea Pig. An account of this animal, with the species to which it is allied, will be found under Hystricidæ.

CAWK. [Barytes.]

CAYENNE PEPPER. [Capsicum.]

CAYMAN. [Alligator.]

CEANOTHUS, a genus of plants belonging to the natural order *Rhamnaceæ*. The calyx is 5-cleft, campanulate, cut round after flowering, with the base permanent and adhering to the fruit; petals hooded, with long spreading claws; fruit dry, 3-celled, loculicidal, with papery valves: cells 1-seeded. The species are smooth or pubescent shrubs, with erect branches; alternate serrated 3-nerved leaves; and very slender white blue or yellow flowers, disposed in terminal panicles, or in axillary racemes. They are natives of North America.

C. Americanus, Red Root, New Jersey Tea, has ovate acuminate serrated leaves, pubescent beneath; flowers arranged in axillary elongated thyrses, with a pubescent rachis. An infusion of the twigs of this plant is used in Canada for venereal diseases. During one of the wars with America the leaves of this plant were used in New Jersey as a substitute for tea. It dyes wool of a fine strong nankin-cinnamon colour, and is a beautiful shrub when in flower.

There are several other species of this genus, natives of North and South America. They are small neat shrubs, with large red roots, which give them the name of Red Root. They grow very well in this country, and may be planted in any common garden soil, and form proper plants for the front of a shrubbery. They may be propagated by layers or seeds. Those from Mexico and the greenhouse species must be protected from frost during the winter. Cuttings will root in sand under a hand-glass.

(Lindley, *Flora Medica*; Don, *Gardener's Dictionary*.)

CEBADI'LLA, CEVADILLA, or SABADILLA, the Spanish-Mexican name for a species of *Veratrum*, the seeds of which are an article of considerable importance in consequence of their having been found to contain a considerable quantity of Veratria. Much interest has been excited about this drug, from the obscurity that is supposed to hang about its origin. It has always been understood to come from Mexico. Retzius, who first referred the Cebadilla to *Veratrum*, had no better materials to describe it from than a bit of the inflorescence which he found among a sample of the seeds. Smith, under *Veratrum* (in 1819), traced out its synonyms in Rees's 'Cyclopædia,' but without throwing much light upon its history. Fée, in 1828, knew no more about it than what Retzius had stated, adding that the meaning of the word was Little Oat—Cebadilla being a diminution of Cebada, the Spanish for Oat. He considered it was fit for use as a horse-medicine, and to destroy vermin. At a later period Descourtilz referred, in his 'Flore des Antilles,' the *Veratrum Sabadilla* of Retzius to a West Indian plant; and shortly after it was ascertained that there was also a Mexican Cebadilla, which corresponded entirely with the seeds of the shops. Thus again Mexico was fixed as the undoubted origin of that valuable production in which the principle Veratria is found more concentrated than in any known plant. Dr. Schiede discovered it in grassy places near the Hacienda de la Laguna in Barranca de Tioselo, on the eastern declivity of the Mexican table-land; and it has been since described by Schlechtendahl and Chamisso under the name of *Veratrum officinale*. Lindley has constituted a new genus for this plant, and calls it *Asagræa officinalis*. It has the following characters:—Root bulbous; plant usually growing in tufts; leaves linear, tapering to the point, even, quite smooth, entire, channeled on the upper side, keeled at the back, four feet long, rather weak; scape naked, as high as a man, quite simple, terminated by a raceme a foot and a half long; perianth deeply 6-parted, spreading, yellowish, small, persistent, with thick blunt linear segments, of which three are rather broader than the others; filaments six, somewhat club-shaped, yellowish, inserted into the base of the perianth, the three that are opposite to the broader segments rather longer than the others, and all longer than the perianth; anthers rather large, yellow, cordate at the base, obtuse; pollen yellow; ovary superior, consisting of three carpels united by their sutures; styles very short; fruit tricapsular, the capsules adhering by their suture, but readily separated; lower flowers hermaphrodite and fertile, upper male, and sterile on account of the abortion of the ovary; flowers have the smell of the Common Barberry. This plant produces the true Mexican Cebadilla or Sabadilla, which is now extensively employed in making the alkaloid Veratria. But in the shops there appear to be seeds of two distinct species, one of which is the *V. Sabadilla*, the other the plant now described, which differs in having linear keeled channeled, and not ribgrass-like leaves, yellow and not purple flowers, segments of the perianth linear and shorter than the filaments, and not ovate or lanceolate, and longer than the filaments. Nearly related to this is a *V. frigidum*, found in the alpine regions of Orizaba, where it flowers in September: this has blackish-brown flowers, and is reckoned a poisonous plant by the Mexicans, who call it Sevoeja. It is referred by Lindley to the genus *Helonias*. [VERATRUM; HELONIAS.]

CEBRIONITES (Latreille), a family of Coleopterous Insects belonging to the section *Malacoderma*. It has the following characters:—Body generally somewhat oval and convex; wing-cases rather soft and flexible; thorax broader than long, widest at the base, and with the hinder angles acute, or produced into a spine. Antennæ generally longer than the head and thorax; mandibles terminating in a simple point; joints of the palpi of nearly equal thickness; legs moderate, not contractile.

The species of this family are frequently found upon plants in marshy situations, but very little is known of their habits; their larvæ are supposed to live in the ground, and very probably subsist on the roots of plants.

The genus *Cebrio* is distinguished from other genera of this family by having all the joints of the tarsi entire, and without any velvet-like pellets beneath, and the posterior thighs of the same size as the anterior. About ten species of this genus have been discovered, most of which are peculiar to Europe. *Cebrio gigas*, a species not uncommon in France, is about three-quarters of an inch in length, and of a pale brownish-yellow colour. In the male the head and thorax and the legs (excepting the thighs) are black; the head and thorax are thickly punctured, and together with the elytra, which are striated, are covered with small yellowish hairs; the antennæ are long, and if extended backwards would reach about half way down the elytra. In the female there is so striking a difference in this organ, as to cause that sex to be mistaken for a distinct species: here the antennæ are very short, and if extended backwards would not reach farther than the base of the thorax; the basal joint is much longer than the other; the fourth and following joints are short, thick, and joined closely together. The legs of the female are also shorter and thicker in proportion than in the other sex.

It is said that the European species of this genus appear in great numbers after heavy rains.

During Mr. Kirby's observations he discovered no less than three parasites, belonging to the *Ichneumonidæ*, on the larva of the insect in question, which accounts for the great difference between the number of larvæ and that of the pupæ.

CECIDOMY'IA, a genus of Two-Winged Flies, belonging to the order *Diptera* and the family *Tipulidæ*. It is known by the following characters:—Wings resting horizontally, and having 3 longitudinal nervures; head hemispherical: antennæ as long as the body, and generally 24-jointed, the joints hairy (in the females 14-jointed); the 2 basal joints short; legs long, basal joint of the tarsi very short, second long.

Mr. Stephens, in his 'Catalogue of British Insects,' enumerates 26 species of this genus. They are always of small size, and many of them deposit their eggs on the young buds of various kinds of plants, where the larva is hatched, and transforms them into galls, in which it subsists and undergoes its metamorphosis.

C. salicina is common in France on willows in the month of May; it is of a blackish colour, covered with fine velvet-like hairs; the antennæ have 20 joints; the wings are slightly obscure and downy; length one-sixth of an inch.

This little fly fixes each of its eggs on a bud of the willow in the month of June. The bud at the time of its evolution, near the end of the month, instead of putting forth its branch, becomes enlarged at the base, and ultimately forms a gall in which the larva is lodged, nourished, and undergoes its metamorphosis: the larva is of a reddish-yellow colour, and assumes the pupa state in the winter, when the gall is become of a large size.

Other species of *Cecidomyia* produce similar deformities upon various parts of many species of plants, and resemble in this part of their habits the *Cynipidæ* among the *Hymenoptera*.

C. Tritici (*Tipula Tritici*, Kirby), an insect commonly known by the name of the Wheat-Fly, has occupied much of the attention of entomologists. Kirby published two accounts of its habits in the 'Linnæan Transactions' (vol. iv.).

This little fly is about one-twelfth of an inch in length, and of a reddish-yellow colour; the wings are milk-white, and exhibit the prismatic colours in certain lights: the eyes are black. The Wheat-Fly may be observed sometimes in the greatest abundance flying about wheat-fields in the month of June. It generally makes its appearance about seven or eight o'clock in the evening. "Although," says Mr. Kirby, "these insects are so numerous in the evening, yet in the morning not a single one is to be seen upon the wing; they do not however then quit the field which is the scene of their employment, for upon shaking the stalks of the wheat or otherwise disturbing them they will fly about near the ground in great numbers. I found their station of repose to be upon the lower part of the culm with their heads upwards." The fly totally disappears by the end of June. According to Kirby, it is about eight o'clock in the evening that they deposit their eggs. He has seen as many as twelve specimens thus occupied at the same time on a single ear, and observes that these flies are sometimes so numerous that, were all to lay their eggs and these to hatch, one-half of the grain would be destroyed.

The eggs are deposited by means of a long pointed and contractile tube, or ovipositor, generally upon the interior valvule of the corolla, just above the stigmata; and it occasionally happens that the fly is unable to retract its ovipositor, and being thus held prisoner it dies.

About the middle of June the larvæ are hatched, and may be seen adhering to the lower end of one of the anthers, and sometimes immersed in the woolly summit of the germen, or in the interior of the valvulæ of the corolla. These larvæ are simple minute grubs, without legs or any visible head, and of a yellowish colour; and their food consists of the pollen of the anthers, which it appears in the plants thus attacked is unfit for impregnation.

The pupæ are of a reddish colour, and in number bear no proportion to that of the larvæ. "I have seen," says Mr. Kirby, "more than once, seven or eight florets in an ear inhabited by the latter, and sometimes so many as thirty in a single floret, seldom less than eight or nine, and yet I have scarcely ever found more than one pupa in an ear, and had to examine several to meet with that. . . . . The pupæ that I have observed have generally been somewhat attached to the grain, and, what is worthy of notice, I never observed them within those florets where the larvæ had taken up their residence; they seem invariably to choose for their habitation, in their immediate state, one where the grain is uninjured, to which they may attach themselves."

In a field of 15 acres (planted partly with white and partly with red wheat), which Mr. Kirby carefully examined, and which was much attacked by these insects, he calculated that the havoc done by them would amount to five combs; he observed that the white wheat was most effected.

CECILIIDÆ (properly CÆCILIIDÆ), a family of Reptiles, which some naturalists have considered as belonging to the Batrachians, but which Cuvier, following Linnæus, places in his third and last family (Les Serpents Nus) of the Ophidians; observing that those who placed it among the Batrachians did so without knowing whether the form underwent a metamorphosis or not. In the 'British Museum Catalogue' of *Amphibia* it stands as a family of the third order of that class (*Pseudophidia*). The following synopsis of the genera is given in the same work:—

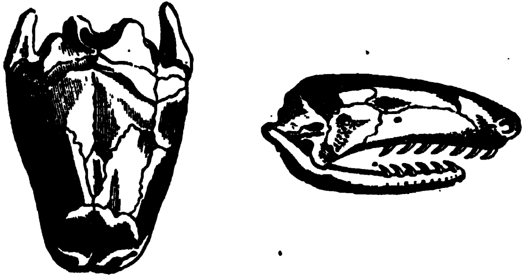
A. Muzzle pitted.

1. *Cæcilia*: the pit under each nostril.
2. *Siphonops*: the pit before each eye; body with broad rings.
3. *Ichthyophis*: the pit before each eye; body with narrow rings.

B. Muzzle not pitted.

4. *Rhinatrema*.

Cæcilia was named by Linnæus from the supposed blindness of the species. The eyes in fact are exceedingly small, and nearly hidden under the skin. Cuvier observes that in some species these organs are wanting altogether; and the following is his description of the genus:—The skin is smooth, viscous, and striated with annular folds. It would appear altogether naked, but on dissection scales well formed are found in its thickness; but these scales are delicate, and disposed regularly in many transverse rows between the wrinkles of the skin, as Cuvier himself saw with certainty in *C. glutinosa*, *C. albiventris*, and other species. The head is depressed; the vent is round, and very near the end of the body; the ribs are too short to circumvent the trunk, and the articulation of the bodies of the vertebræ is effected by facets with hollow cones, the depression in which is filled with a gelatinous cartilage, as in the Fishes and in some of the Batrachians. Their skull is united to the first vertebra by two tubercles, as in the Batrachians, a mode of union approached by the *Amphisbænæ* only among Serpents. Their maxillary bones cover the orbit, which is only pierced in the form of a small hole, and the temporal bones cover the temporal fossa, so that the head when examined from above presents only a continuous bony shield. Their os hyoides, composed of three pairs of arches, may have led to the supposition that in early youth the bones supported gills. The maxillary and palatal teeth are arranged on two concentric lines, as in the *Protei*, but are often sharp and curved backwards, as in the true serpents. The opening of the nostrils is at the back of the palatè, and the lower jaw has no moveable pedicle, while the tympanic bone is dovetailed (enchassé) with the other bones into the shield of the skull. The only ossiculum auditus, or auditory bone, is a small plate upon the fenestra ovalis, as is the case with the Salamanders.



Skull of a species of *Cæcilia*.

The auricle of the heart in these animals is not divided sufficiently deep to be regarded as double, but the second lung is as small as it usually is in the other serpents. The liver is divided into a great number of transverse leaves (feuillets). In their intestines Cuvier states that there is to be found a quantity of vegetable matters, vegetable earth, and sand.

The following species are given in the 'British Museum Catalogue:'—

C. gracilis, a native of South America. It is the *C. vermiformis* of Shaw.

C. tentaculata. It is the *C. albiventris* of Daudin.

C. compressicauda, a native of Guyana.

C. rostrata, a native of South America.

C. oxyura, from Malabar.

C. squalostoma, from Africa.

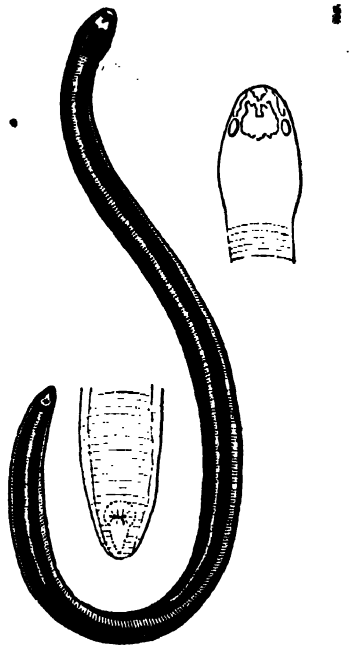
There are two species of *Siphonops*:—

S. interrupta (*C. annulata*, Mikan). It is a native of the Brazils.

S. Mexicana is a species found in Mexico.

The genus *Ichthyophis* has but one species, the *I. glutinosus* (*C. glutinosa* of Linnæus). It is a native of Ceylon.

The *C. bivittata* of Cuvier constitutes the genus *Rhinatrema*. The only species, *R. bivittatum*, is a native of Cayenne.



Cæcilia bivittata, Cuvier (*Rhinatrema bivittatum*, Dumeril).

CECROPIA, a genus of plants belonging to the natural order *Artocarpaceæ*. *C. peltata* yields from its juice caoutchouc. The bark is astringent. The stems are hollow; and its light porous wood is used by the natives of the countries where it grows to give light by friction. It is a native of South America.

CECROPS, a genus of Entomostracous *Crustacea*, the type of the *Cecropidæ*, a family of the *Pæcilopoda*. [PŒCILOPODA.]

CEDAR-BIRD. [BOMBYCILLA.]

CEDAR-TREES. [ABIES.]

CEDRELA, a genus of plants, the type of the natural order *Cedrelaceæ*. It has the following characters:—Calyx 5-toothed; petals adnate to the torus; stamens 5, distinct; capsule 5-celled, 5-valved; seeds numerous, on each side of the dissepiment ending in a wing.

C. Toona, Bastard Cedar, has lanceolate leaflets, acuminate, entire, pale glaucous beneath. It is a native of the East Indies, where it is called Toon. It has an erect trunk of great height and size, with smooth gray bark. The flowers are very numerous, small, white, fragrant, like honey. The seeds are numerous, imbricated, winged. The bark is a powerful astringent, and is said to be a good substitute for Peruvian Bark in the cure of periodic diseases. Dr. Blume used it in Java with much success in the various forms of fever, dysentery, diarrhœa, &c. Horsfield also used it in dysentery.

C. odorata has leaflets ovate-lanceolate, entire, on short stalks. It is a native of Barbadoes and the Caribbee Islands. It is a large tree with a rough bark. The fruit is about the size of a partridge-egg. When fresh the bark and berries smell like assafœtida. The trunk is hollowed out into canoes. The wood is of a brown colour and has a fragrant odour, from which circumstance it is called Cedar in the British West India Islands. It is frequently cut into shingles for covering houses, but it is not adapted for ship-building on account of its being subject to the attacks of worms. It is not adapted for casks, as it gives its odour to whatever is placed in contact with it.

C. febrifuga (*Soymidia febrifuga*) has leaflets ovate-oblong, acuminated, quite entire. It is a native of Java. Its bark is said to have a better effect on some of the fevers of India than cinchona. It is also a powerful astringent. The wood is good for many purposes.

CEDRELA'CEÆ, a natural order of plants, belonging to the Syncarpous group of Polypetalous Exogens. The species are timber-trees: the timber is usually compact, scented, and beautifully veined; the leaves are alternate, pinnated, without stipules; the flowers are in terminal panicles. The essential characters of the order are: Calyx 4-5-cleft, petals 4-5, longer than the sepals; stamens 8-10, the filaments either curled into a tube or dinstinct, and inserted into a hypogynous disc; the style and stigmas simple; the cells of the ovary equal in number to the petals or flower, with the ovules 4 or often more, imbricated in two rows; the first capsular with the valves separable from the dissepiments, with which they alternate; the seeds flat, winged; albumen thin or none. This order is nearly related to *Meliaceæ*, from which it is chiefly distinguished by its winged and indefinite seeds.

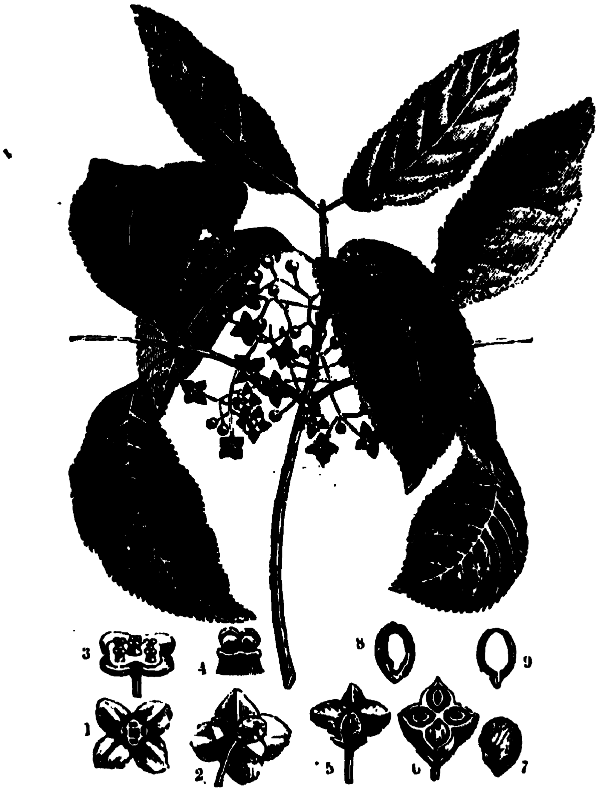
The dotted leaves of some species connect this order with *Aurantiaceæ*. It contains 9 genera and about 25 species.

An essential oil called Wood-Oil is found in *Chloroxylon Swietenia*, which is a native of the East Indies. The wood is of a deep yellow colour, and called Satin-Wood, remarkably close-grained, heavy, and durable, and comes nearer to box-wood than the produce of any other tree. *Flindersia* possesses a volatile oil. *F. Australis* is a native of Australia, and its wood is said to be not inferior to mahogany. *F. Amboinensis* is a native of the islands of Hitu and Ceram. The spiny part of the fruit is formed into rasps. It was on this account called by Rumphius *Arbor radulifera*. *Oxleya xanthoxyla* is a native of Australia. It attains a height of 100 feet. The wood is yellow, and employed for building boats. It is called Yellow-Wood. [Swietenia; Cedrela.]

(Lindley, *Flora Medica;* Don, *Gardener's Dictionary;* Lindley, *Natural System.*)

CELANDINE, a name properly applied to the species of *Chelidonium.* [Chelidonium.] It has however been given by some of our poets to the *Ranunculus Ficaria,* Linnæus (*Ficaria verna* of others), the vulgar name of which is Pilewort. [Ranunculus.]

CELASTRA'CEÆ, *Spindle-Trees,* the Spindle-Wood Tribe, a natural order of Polypetalous Exogens, consisting of shrubs or trees principally found in temperate latitudes, and not abounding in either the colder or the hotter parts of the world. They are found in Europe, Asia, North America, and South Africa. They have simple alternate or opposite leaves, a small number of perigynous stamens inserted into a fleshy disc and alternate with the petals; a superior syncarpous ovary immersed in the fleshy disc; and a superior capsular or succulent fruit, with a small number of ascending seeds. The order is not of much economical importance. A slight degree of acridity is said to have been detected in some of the species. *Euonymus Europæus,* the Spindle-Tree, the wood of which is used for butchers' skewers, is the commonest European form of this order.



Euonymus atropurpureus.

1, A front view of the flower; 2, the same from below, showing the calyx; 3, a view of the disc, with the stamens growing on it; 4, a stamen; 5, a ripe fruit; 6, a cross section of the same; 7, a seed; 8 and 9, sections of the latter.

The barks of *Celastrus scandens* and *C. Senegalensis* are said to be purgative and emetic, whilst the species of *C. venenatus* are reported to inflict the most painful wounds. The fruits of *Elæodendron ruber* are eaten at the Cape of Good Hope. The relations of the order are according to Lindley expressed thus:—

Aquifoliaceæ.
Sapotaceæ. Celastraceæ. *Hippocrataceæ.*
Euphorbiaceæ.

It has 24 genera and 260 species.

CELERY. [Apium.]

CELESTINE, the Native Sulphate of Strontia. It has its name from its pale blue colour. [Strontia.]

CELL, VEGETABLE. [Cells; Histology; Tissues, Vegetable.]

CELLARIA. [Cellariæa.]

CELLARIÆA, or CELLARIADÆ, the second family, according to De Blainville's arrangement, of the sub-class *Polypiaria Membranacea.*

Animals hydriform, provided with very delicate ciliated tentacula, separated, distinct, contained in oval flattened membranous cellules, with a bilateral subtermined crescentic opening; usually provided with a moveable cartilaginous lip, forming by their lateral junction, in one or two tiers or stages, a cretaceous or membranous, limited, diversiform, and fixed polyzoarium. Ovicells external, globose, above the aperture of the cell.

This group corresponds pretty nearly with the *Escharadæ, Flustradæ,* and *Cellariadæ* of Fleming, and the *Escharina* and *Celleporina* of Ehrenberg; it also includes part of the sub-order *Cheilostomata,* of the *Polyzoa infundibulata* of Mr. Busk's 'Catalogue of Marine Polyzoa.' For further particulars respecting the structure of the animals and their habitations, reference must be made to Polyzoa, a few only of the principal forms being here noticed.

We shall notice here the principal generic forms of this group.

1. *Lunulites.* The number of species of this generic group, of which until lately only a few fossil forms were known, has been much augmented by the addition, not only of other fossil species, but also of several recent ones. The latter have also afforded a much more precise insight into the structure of the peculiar polyzoarium than it was possible to obtain from the inspection merely of fossil specimens. The division of the genus suggested by Lamouroux seems to be sufficiently founded in nature to justify its definitive adoption so far as it goes; and, in addition, a recent form described and figured in the 'Voyage of H. M. S. Rattlesnake' would seem to indicate the propriety of instituting a third generic or sub-generic type.

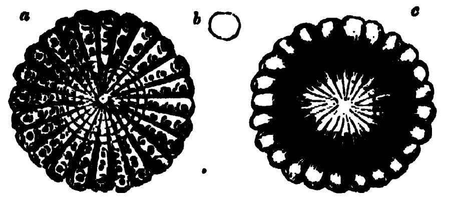
In all these forms the polyzoary, which is more or less regularly circular, convex above, and concave or flattened below, presents cells of two kinds—one set of which may be termed secondary or accessory; and it is according to the relative position of these cells as regards the others that the division of the genus is founded.

In one case the secondary cell, which is then considerably smaller than the other, is situated at the apex of the primary cell, immediately above the aperture (*Cupularia*). In a second form any distinction of size between the two sorts of cells is less or not at all obvious. The two sets of cells however are very differently arranged from those in the former case; the secondary being disposed more or less regularly in longer or shorter rows, alternate with the others, and like them radiating from the centre (*Lunulites*). Of the former of these forms the Lunulite en Parasol of Defrance may be taken to afford a tpe, and of the latter, *L. radiata.* In the third form the secondary cells are scattered more irregularly over the surface of the polyzoary. In this case the secondary cell is also superior to one of the other kind.

From the examination of recent forms it has been ascertained that the secondary cell probably contains nothing more than a mass of muscular substance for the movement of a vibratile spine or seta, of various forms and structure, and which corresponds with the vibraculum, or moveable setose organ, which is found on several of the *Polyzoa,* and particularly in the genus *Scrupocellaria.*

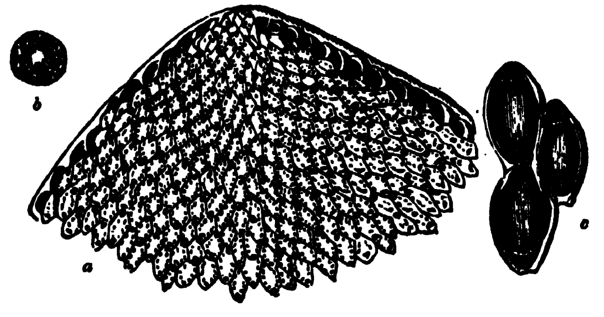
The arrangement of the group therefore into three genera would appear to be justifiable and convenient, namely, *Lunulites, Cupularia,* and *Selenaria;* which may be thus defined:—

Lunulites, Lamouroux. Polyzoarium circular or irregular, convex above, concave or flattened beneath; cells arranged in series



Lunulites radiata.

a, View of the Upper Side, magnified; *b,* natural size; *c,* View of Lower Side, magnified.



Defrance's Lunulite en Parasol.

a, A Portion magnified; *b,* natural size; *c,* three cells highly magnified.

radiating from the centre, and separated by alternate rows of cells supporting vibracular spines; under surface usually with radiating striæ, and the surface with minute perforations.

Recent species :—

L. capulus, Busk; 'Voyage of Rattlesnake.'
L. gibbosa, Busk; 'Cat. Brit. Mus.' pl. 112.
L. cancellata, Busk; „ „ pl. 113.

Cupularia, Lamouroux. Polyzoarium circular, regular, convex on the upper side and concave below; cells disposed quincuncially, each with a smaller vibracular cell at its summit; under surface with radiating lines, grooves, or ridges, or divided into sub-hexagonal areas; surface perforate or imperforate, smooth, or granular.

Recent species :—

C. Guineensis, Busk; 'Cat. Brit. Mus.' pl. 114.
C. Owenii, Gray; „ „ pl. 115.
C. Lowei, Gray; „ „ pl. 116.
C. stellata, Busk; „ „ pl. 118.

Selenaria, Busk; 'Cat. Brit. Mus.' Polyzoarium circular, regular, convex above, concave below; cells disposed quincuncially, some (closed in front by a cribriform calcareous plate) furnished with a superior vibraculum.

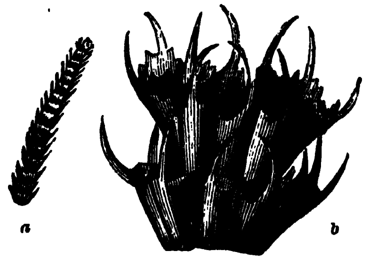
Recent species :—

S. maculata, Busk; 'Voy. of Rattles.;' 'Cat. Brit. Mus.,' pl. 117.

Example, *Lunulites radiata*. Locality, Grignon, &c.

2. *Electra*. Animals unknown, contained in membranous vertical bell-shaped cellules, ciliated on the edges, and shut by a diaphragmatic membrane, with a very small and semilunar opening, and disposed in a verticillate form around an ideal axis.

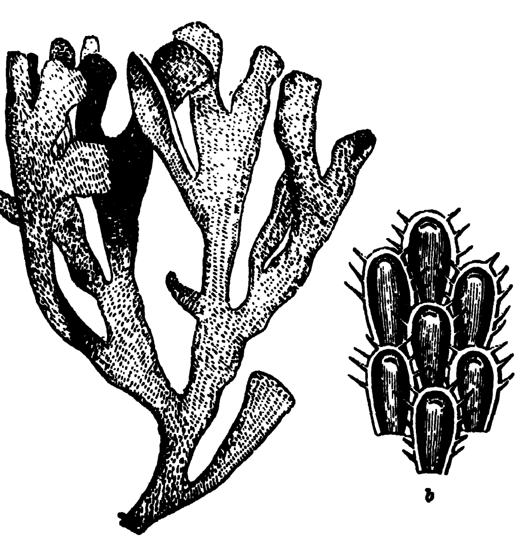
Example, *Electra verticillata*.



Electra verticillata. *a*, natural size; *b*, magnified.

This is the *Flustra verticillata* of Gmelin (*Sertularia verticillata* of Esper); and this genus, which was separated by Lamouroux, scarcely deserves, as De Blainville remarks, to be distinguished from *Flustra pilosa*, whose cellules are occasionally somewhat verticillated; but in this he confounds two things perfectly distinct, though often misconceived.

3. *Flustra*. Cells contiguous; on both sides of the frond.



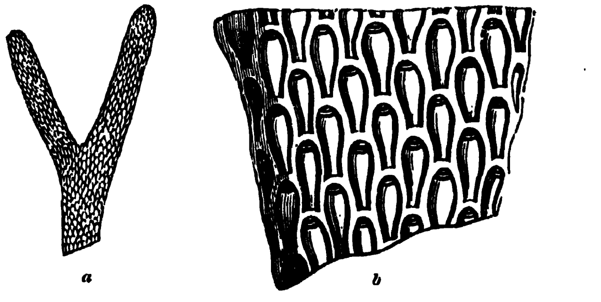
Flustra foliacea. *a*, natural size; *b*, some of the cells magnified.

4. *Carbasea*. Cells contiguous; on one side only of the frond.

Example, *Flustra carbasea*. Locality, seas of Scotland, &c.

Sir John Dalyell, in his interesting paper entitled 'Further Illustrations of the Propagation of Scottish Zoophytes' ('Edinburgh New Philosophical Journal,' April-July, 1836), gives the following account of the propagation of the *Flustræ*. Speaking of *Alcyonium*, he says, "We find it consists of a compact gelatinous or fleshy matter, studded with innumerable cells sunk in its substance, which are inhabited by vivacious hydræ. Different species or varieties occur in the Scottish seas, especially the *gelatinosum*, and a thin green flattened palmate kind, which has perhaps escaped the notice of naturalists hitherto. A white, opaque, ovoidal or nearly circular flattened corpusculum, previously invisible, issues from the fleshy part of these products whence it seems to be elicited, particularly by the influence of light. On removal of a small specimen that had already afforded many from a dark situation to a moderate degree of light, at least 150 quitted their recesses within an hour. These beings are endowed with much greater activity than the corpuscula of the *Actinia;* their courses are alike diversified; they swim through the water in all directions, regularly and irregularly, ascending to the surface or descending to the bottom, pursuing a straight line, describing an orbit, or tumbling about among the neighbouring substances. Meanwhile, as if of soft consistence, their form alters, and the action of the cilia environing the body is alternately depressed and relaxed. At length, having become stationary, a margin diffuses around the body, and supervening transparence of the centre soon exposes an inanimate hydra within, which in nine or eleven days is displayed perfect from its cell. The inner surface of each tentaculum is now clothed by a double row of stout dark cilia in rapid motion, but in opposite directions; for as those of one side strike upwards those of the other strike downwards. Further diffusion of the basis adhering below forms additional compartments for other hydræ. The propagation of the *Flustræ carbasea, foliacea,* and *truncata* ensues after a similar fashion. A ciliated corpusculum, spherical, ovoidal, or irregular, quits the leaf, pursues its course in the water, becomes stationary, adheres, and a nascent *Flustra* arises from the spot. Above ten thousand such corpuscula have been produced by a moderate-sized specimen of the *Flustra foliacea*, tinging the bottom of a vessel yellow from their multitude, and vitiating the water by their decay."

The same author, in the 'Proceedings of the British Association' (Edinburgh, September, 1834), thus clearly and elaborately describes the organisation of *Flustra carbasea* :—"The *Flustra carbasea* resembles a leaf divided into subordinate parts, one of the surfaces being studded with cells, and the other exhibiting elevations or convexities corresponding to their bottom, and the whole product is of a yellowish colour. Each cell, of a shuttle or slipper shape, level with the surface of the leaf, is inhabited by a vivacious polypus, exercising a percussive faculty both of the tentacula individually and of the whole head. Some of the cells are occupied occasionally by large bright yellow, irregularly globular, solid, ciliated animalcula, subsequently quitting them to swim heavily below. In several days they become motionless like the former, and die also without immediate decomposition. Next, there appears in just about the same spot below, occupied by the motionless animalculum, a yellow nucleus with a lighter diffusing margin. This in its further diffusion assumes a shuttle or slipper form; it becomes a single cell, which afterwards displays a polypus under the wonted figure and action. The adult *Flustra* was vertical, for the leaf is always erect; but here the new cell is horizontal. By a singular provision of nature, as only one side of the adult is cellular, the original cell is necessarily a root, sole, or foundation to admit subsequent enlargement, which in such zoophytes is always from a single cell. One end of the cell next rises vertically, wherein a second cell, with its polypus, is soon displayed overhanging the first, and at right angles to the plane of its position." (See also Professor Grant's 'Observations on the Polypes' of this species in the 'Edinburgh New Philosophical Journal.')



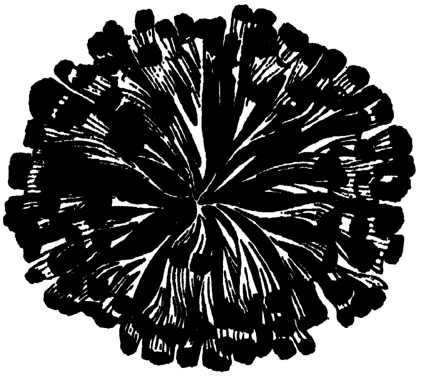
Flustra carbasea. *a*, A Portion, natural size; *b*, a Portion magnified.

Example, *Flustra avicularis*. Locality, European seas; Seaford Bay, Sussex.

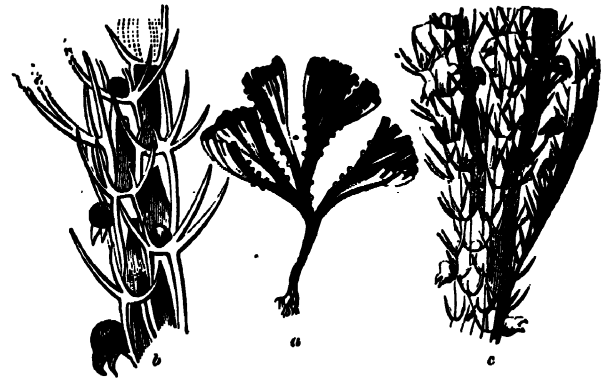
This species however should be removed from the genus *Flustra* altogether, as its affinities are clearly with that of *Bugula* (Oken). It is the *B.* (*Avicularia*) *flabellata*, J. V. Thompson, 'Manuscript, Brit. Mus.,' and its avicularia, or 'bird's-head' processes, from their size and transparency, are well adapted for the investigation of the structure of those curious organs.

5. *Elzerina*. Animals unknown, contained in sufficiently large oval elongated subhexagonal bordered cellules, having a membranous tympanum or drum, in which is pierced the sigmoid opening, forming by their quincuncial and circular arrangement the branches of a

membranous, plant-like, non-articulated, dichotomous, and fixed polyzoarium.



Flustra avicularis. Showing a spherical mass of the natural size.



Flustra avicularis.
a, A Specimen showing the root and branching form of the natural size; *b*, *c*, portions magnified. From Sowerby's 'British Miscellany,' London, 1806.

Example, *Elzerina Blainvillii.* Locality, the seas of Australia.

Elzerina Blainvillii.
a, natural size; *b*, a portion magnified.

De Blainville observes that this genus was established by Lamouroux for a polype brought from the seas of Australia by Péron and Lesueur, which De Blainville examined in Lamouroux's collection, and that he has been satisfied that it is a genus which can hardly be distinguished from the phytoïd or plant-like *Flustræ*,—that it differs from them only in the union of the cellules, which form a circular quincunx, as in *Cellaria Salicornia*, and are still more soft and membranous.

Risso records two species of *Elzerina* in the Mediterranean, *E. venusta* and *E. mutabilis*; but De Blainville observes, that if it be true that their cellules are scattered, it is probable that those species do not belong to this genus, the characters of which it must be confessed are by no means at present well defined.

6. *Vincularia* (recent and fossil). Animals unknown, contained in oval subhexagonal regular cellules, having a subterminal semilunar orifice, and applied and united longitudinally in many rows, so as to form a cretaceous brittle polyzoarium, in the form of a little wand.

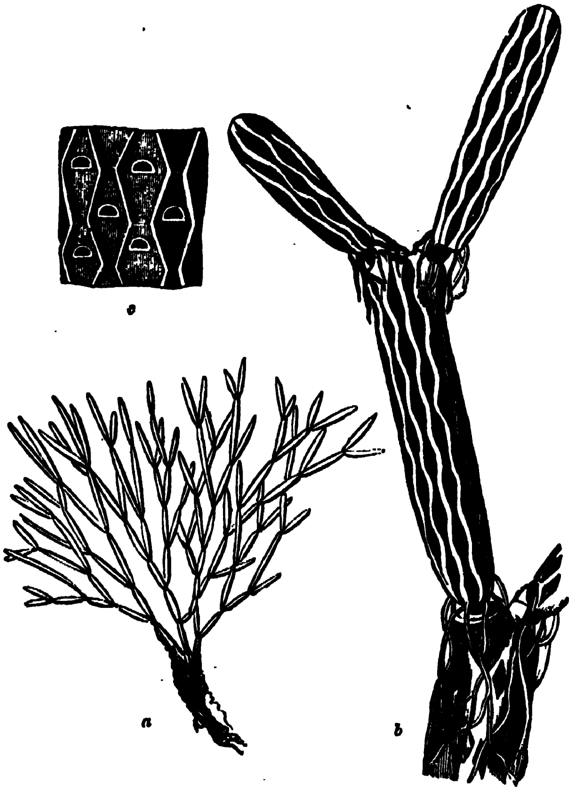
Example, *Vincularia fragilis.* Locality of the genus at present known, the Calcaire Tertiaire of Westphalia. A recent species occurs in the Pacific or Australian seas, and is figured in 'Cat. Brit. Mus.' pl. 65, *V. gigantea.*

De Blainville observes that this genus was established by Defrance, and that it has been adopted by Goldfuss under the denomination of *Glauconoma*, a denomination which De Blainville rejects, remarking that Goldfuss regards it as approaching nearly to *Cellaria Salicornia*, and stating that the *Vincularia fragilis* which he (De Blainville) examined in Defrance's collection might well be nothing more than a true *Flustra*, which is found in the same beds with *V. fragilis.* De Blainville adds in support of this opinion that Defrance showed him a specimen which was composed of two rows or series, instead of a single series only.

7. *Salicornaria.* Cells disposed around an imaginary axis, forming cylindrical branches of a dichotomously divided erect polyzoarium.

a. Species with Hexagonal Cellules, and with a transverse aperture. (Genus, *Salicornia* of Cuvier.)

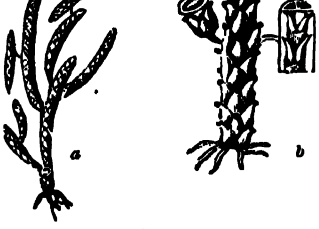
Example, *Cellaria Salicornia* (*Cellularia Salicornia* of Pallas; *Tubularia fistulosa* of Linnæus). Locality, European seas.



Cellaria Salicornia.
a, natural size; *b*, a portion magnified; *c*, a smaller portion still more highly magnified.

β. Species with Oval Cellules, and the aperture rounded and tubular.

Example, *C. ceroïdes* (*Sertularia ceroïdes* of Gmelin). Locality, Mediterranean and the Indian seas.



Cellaria ceroïdes.
a, natural size; *b*, a portion of the lower part magnified.

De Blainville observes that this genus, established by Pallas under the name of *Cellularia*, has been successfully simplified by Lamarck and by Lamouroux, who has established many genera at its expense. De Blainville further states that before Delle Chiaje no author who had described a species of a true *Cellaria* was known; but that the Neapolitan observer had filled this gap by informing us in his Memoirs that the polypes of *C. ceroïdes* bear a perfect resemblance to those of *Millepora* (*Myriapora*) *truncata.* Pallas made a curious observation relative to the rapid growth of *C. Salicornia*; for he found individuals an inch and a half long upon the eggs of *Squali*, which were still far from the time when the young are excluded. The genus as here characterised should perhaps rather be regarded as a family group, under which would be included two, if not three, genera, should the species here noticed and figured as *C. ceroïdes* prove to be a cheilostomatous polyzoan. The genera are *Salicornaria* (Cuvier), *Nellia* (Busk, 'Cat. Brit. Mus.').

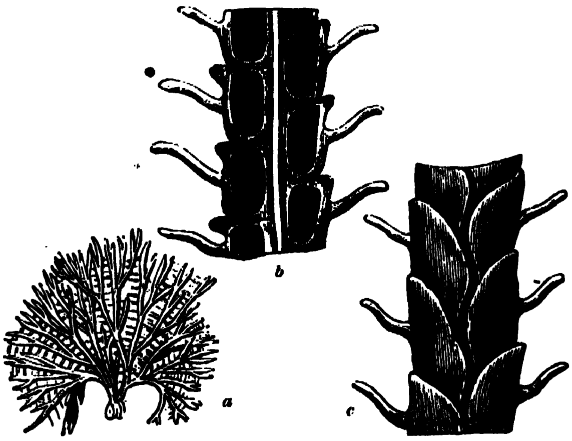
8. *Intricaria* (fossil). Animals unknown, contained in hexagonal elongated cellules with elevated borders, and covering the entire surface of a calcareous polyparium sufficiently solid, rush-like (joncacé) internally, composed of a considerable number of cylindrical branches irregularly anastomosed.

Example, *I. Bajocensis.*

De Blainville observes that this genus was established by Defrance for a pretty fossil polypier found by M. de Gerville in the department of La Manche; and he states that on examining it in the collection of the first named of those naturalists, he was satisfied that it approaches very nearly to the *Cellariæ*, and especially to *C. Salicornia* in the form of its cellules, while however it differs from it because it is not articulated, and because in all probability it did not adhere by radical fibrils. Lamouroux, he adds, thought it was a Millepore. At all events its place here seems to be doubtful.

9. *Canda.* Animals unknown. Cells rhomboidal, situated on the outer side for the lodgment of a vibraculum; no avicularium on the upper and outer angle.

Example, *C. arachnoïdea*, Lamouroux (*Cellaria filifera*, Lamarck). Locality, seas of Australia.



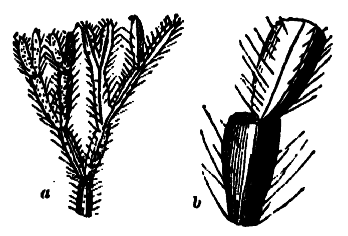
Canda arachnoïdea. *a*, natural size; *b*, *c*, portions magnified.

De Blainville observes that this genus was established by Lamouroux for a species of *Cellaria* brought by Péron and Lesueur from the Australian seas, and which he saw in Lamouroux's collection, which now forms part of the Museum of Caen. The assemblage of cells resembles the vertebral column of a fish. Upon one of the surfaces are two rows of alternate cells, separated by an angular crest. Upon the other surface may be seen the back of the cells, with tubular filaments which reach transversely from one branch to another, and are analogous to the radiciform, or root-like tubes. He adds that it would appear that these transverse fibrils are sometimes wanting, as in the variety noted by Lamarck.

To this genus, as thus defined, also belongs *Canda reptans* (*Cellularia reptans* of our coasts).

10. *Caberea.* Animals unknown. Cells bi-multiserial, in the latter case quincuncial; back of branches furnished with large vibracula, which are placed obliquely in two rows, diverging in an upward direction from the middle line, where the vibracula decussate with those of the other; avicularia, when present, sessile on the front of the cell.

Example, *C. dichotoma.*



Caberea dichotoma. *a*, natural size; *b*, two cellules magnified.

British species. *C. Borgi* ('Audouin,' Savigny, 'Egypt,' pl. 12, f. 4); *C. Hookeri* (John's 'Brit. Zooph.' Ed. 2, pl. 60); but these two species have been confounded.

11. *Bugula.* Polyzoarium erect, phytoid, dichotomously divided into narrow ligulate bi-multiserial branches; no vibracula; avicularia when present pedunculate and articulated; cells elliptical (viewed behind), closely contiguous, aperture very large, margin simple, not thickened. (Colour not unfrequently red or blue.)

Example, *B. Neritina.* Locality, Mediterranean.

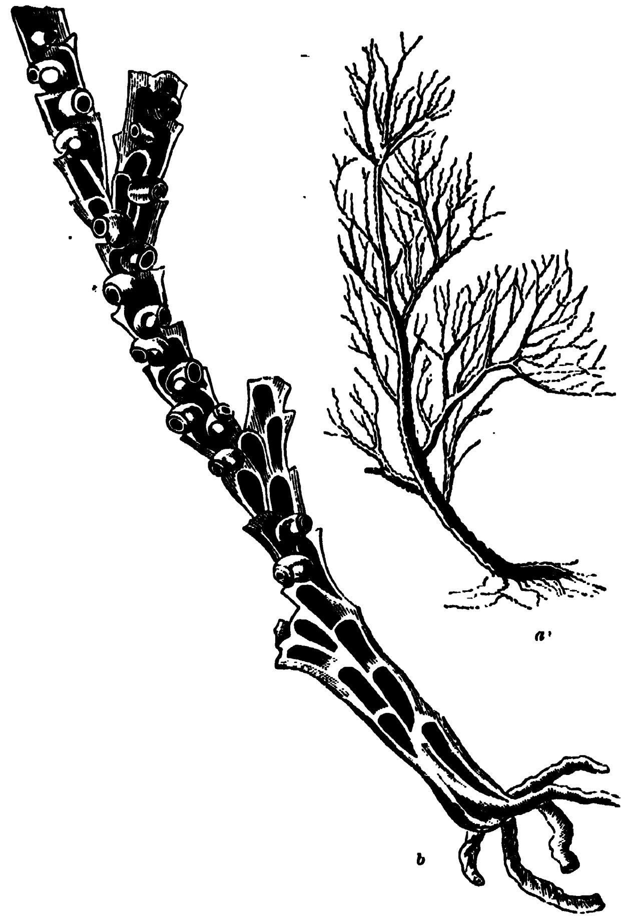
This genus was established by Oken, and was also constituted by Lamouroux under the name of *Acamarchis*; but was not adopted by Lamarck, nor by Dr. Fleming, who, according to De Blainville, confounds it with *Bicellaria.*

12. *Bicellaria.* Polyzoarium erect, phytoid, dichotomously divided into narrow ligulate biserial or multiserial branches; no vibracula; avicularia when present pedunculate and articulated; cells turbinate, distant; aperture directed more or less upwards; several spines, marginal or dorsal.

To the same family belong *Halophila* (Gray); *Bugula* (Oken).

Example, *Bicellaria ciliata*, *Sertularia pilosa.* Locality, European seas.

This division of *Cellariadæ*, *Crisiæ* of Lamouroux, *Cellariæ* of Lamarck, was separated by Dr. Fleming, who gave it the denomination of *Cellularia*, a name preoccupied as we have seen by Pallas for the whole family. Instead of this name De Blainville proposes that here given, and observes that Savigny, in the plate which he has devoted to *Cellariæ* in his great work on Egypt, has figured the solid part of four species, which being composed of two ranks of cellules should belong to this section.



Acamarchis Neritina. *a*, natural size; *b*, lower portion magnified.

13. *Notamia.* Cells opposite, in pairs; a pair of tobacco-pipe-shaped avicularia above each pair of cells, each arising from the inferior tubular prolongation of one of the cells in the pair next above.

Example, *N. bursaria.* Locality, European seas, &c.

This is the *Sertularia bursaria* of Linnæus, *Cellularia bursaria* of Pallas, *Dynamena bursaria* of Lamouroux.

To the same family belong *Gemellaria* (Savigny), *Didymia* (Busk), *Dimetopia* (Busk).

14. *Scruparia.* Cells uniserial; junctions rigid, or of the same consistence as the cells; polyzoary adnate or erect.

Example, *S. chelata*, Ellis and Linn.; *Cellularia chelata*, Pallas; *Eucratea chelata*, Lamouroux; *E. loricata*, Fleming. Locality, European seas.

In the same family are included *Hippothoa* (Lamouroux); *Ætea* (Lamouroux); *Beania* (Johnst.).

Lamouroux broke up this generic division into the genera *Eucratea* and *Lafoea.* De Blainville says that *Unicellaria*, under which he includes *Scruparia*, is easily characterised by the solitary disposition of its cellules, and that he had examined both *Eucratea* and *Lafoea* in Lamouroux's collection at Caen, and found the differences of too little value to warrant the separation.

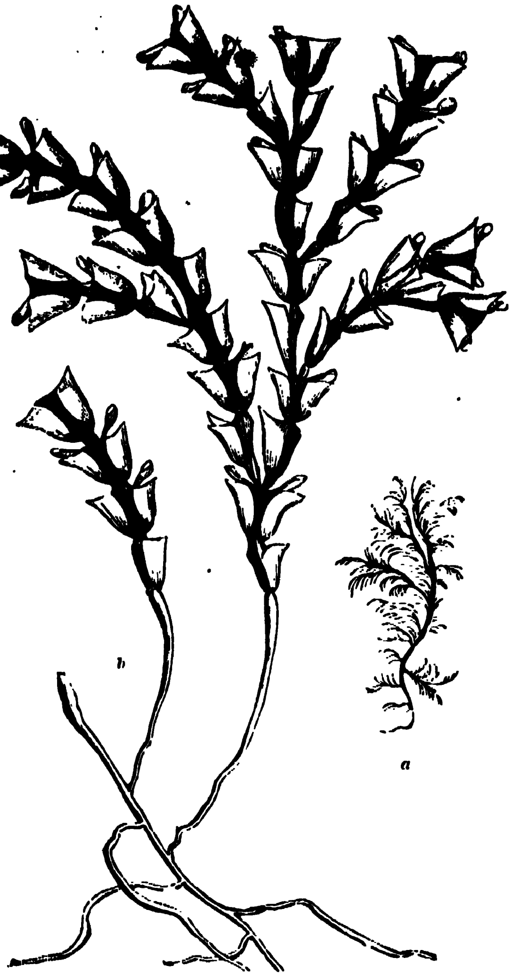
15. *Catenicella*, De Blainville; *Catenaria*, Savigny. Animals unknown; contained in calcareous cells arising one from the upper and back part of another by a short corneous tube, all facing the same way and forming dichotomously divided branches of an erect, phytoid, polyzoary cell, at each bifurcation geminate.

16. *Menipea.* Cells oblong, or attenuated downwards, imperforate behind, with a sessile avicularium, frequently absent on the upper and outer angle, and one or two sessile avicularia on the front of the cell below the aperture.

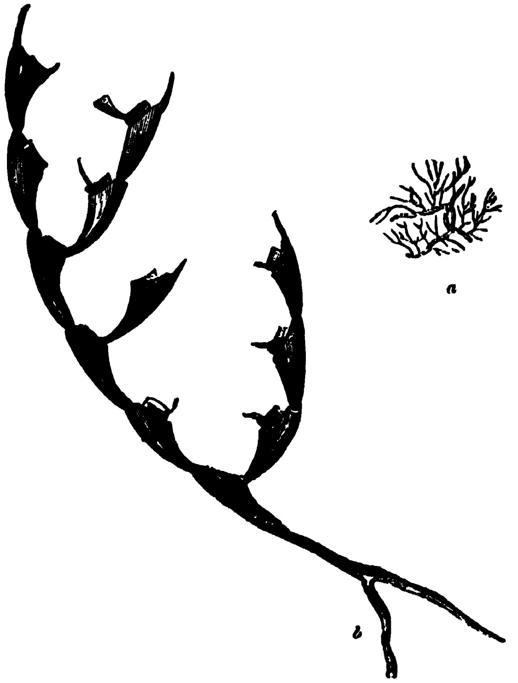
Synonyms. *Cellaria* (part), Linnæus, Solander.
Crisia (part), Lamouroux.
Tricellaria, Fleming, De Blainville, Gray.

The essential distinctive character of this genus, as here intended, consists in the presence of one or more sessile avicularia on the front of the cell below the aperture, and usually of a sessile avicularium at the upper and outer angle; no vibraculum. With the exception of one or perhaps two species the *Menipea* have three or six cells only in each internode; the branches consequently are loose and straggling, and usually incurved at the extremities, as is best seen in *M. cirrata.*

The genus appears to enjoy a wide geographical range, occurring from the Arctic Circle to the southern points of America and Africa.



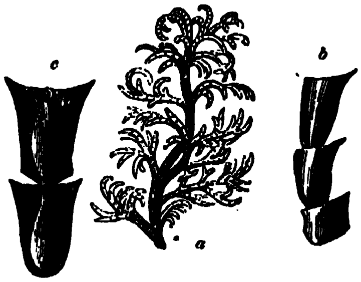
Notamia bursaria. *a*, natural size; *b*, a portion magnified.



Scruparia chelata. *a*, natural size; *b*, a portion highly magnified.

This genus (of which seventeen species are described and figured in the 'Cat. Brit. Mus.') admits of division into three subgeneric groups. The species are for the most part Australian, and with the exception of that described by Savigny, which might have been procured in the Red Sea, appear to be limited to the Southern Hemisphere.

The *M. hyalæa*, of which a figure is here given from Lamouroux, appears to be referrible to this genus.



Menipea hyalæa. *a*, natural size; *b*, *c*, cellules magnified.

For the best account of the species of this and other families of the *Polyzoa* the reader is referred to Mr. Busk's complete and beautifully illustrated 'Catalogue of the Marine Polyzoa' in the collection of the British Museum. [POLYZOA.]

CELLASTRÆA. [MADREPHYLLIÆA.]

CELLIPORA. [POLYZOA.]

CELLS. The ultimate structure of animal and vegetable bodies consists of minute vesicles which are called Cells. In both animal and vegetable structures these organs are not generally visible to the naked eye, as they vary from the 1-500th to the 1-10000th part of an inch in diameter. In all cases they consist of an enveloping membrane or cell-wall, which incloses in a space more or less enlarged certain constituents, called cell-contents. The nature of the substances which enter into the composition of the cell-walls and constitute the cell-contents, differs in the animal and vegetable kingdoms, but there are certain properties which all cells possess in common. Sometimes these properties are called vital, to distinguish them from the properties possessed by inorganic or mineral bodies, which are called physical. It will however be seen that, independent of the formative power by which particles of gelatine, cellulose, &c., arrange themselves in the form of cells, and again these cells arrange themselves into the forms of organs and beings of a specific form, there are few of the functions performed by cells that may not be referred to the action of physical forces. One of the first and most necessary conditions of the cell is, that it shall allow of the passage, through the membrane of which its walls are composed, of those substances by means of which it grows, and which it acts upon for the production of the peculiar secretions which characterise either specific beings or parts of their organisation. This function, which is called Absorption, seems referrible to the physical relations which exist between liquids and gases and the membrane of which the cell-wall is composed. [ABSORPTION.]

The liquid or gaseous contents which are thus introduced into the interior of cells undergo a variety of changes, according to the position, age, or other circumstances of the cell. Sometimes the fluid that is absorbed appears to be transmitted in compound structures from cell to cell without undergoing any great amount of change. In other cases the most decided chemical changes take place in the elements introduced. The cells of some parts of vegetable structures are an instance of the latter, in which carbonic acid and ammonia are absorbed with water, and converted, either during their passage through the cell-wall, or whilst in the interior of the cell, into cellulose, starch, sugar, protein, and other constituents of the cell. In other parts of plants the cells convey solutions of sugar and other substances without producing on them any change.

The constituents absorbed into the interior of the cell are the materials from which the cell-wall and all its contents are derived. The process by which the cell appropriates to itself these matters is called Assimilation. This function is supposed to be carried on by an independent force or power residing in the cell, or congeries of cells, which form an organ or a body, and has been called the 'assimilative force or property,' 'organising force,' 'plastic force.' It is necessary however in this process to separate between the changes by which one substance is converted into another, and which is probably the result of ordinary chemical force under other circumstances, and the power or force by which these substances are made to assume definite forms in cells and organs. The latter is a special force in the case of each cell, plant, or animal, and to which alone, of the changes involved in the function of assimilation, the term vital can be properly applied.

The result of the appropriation of the new matter absorbed from without in all cells is their enlargement or growth. This takes place in two ways: either the new matter is taken up into the interior of the substance of the cell-wall, which is always the case where the cell becomes augmented in size, or it is deposited in the form of layers in the interior of the cell. According as the first mode of growth is regular or irregular will be the form of the cell. The vegetable and animal kingdoms present almost all conceivable forms of cells, from the spherical and hexagonal cells observed in the lower forms of plants, and the less organised tissues of animals, as cartilage, up to the elongated vessels of the plant, and the irregular cells of bone or areolar tissue in animals. The animal kingdom presents by far the greatest variety in this respect, and so great are the changes that some of the animal cells undergo, that the terms Metamorphoses or Transformations have been applied to these changes. As examples of these cells we may quote—the horny scales of the epidermis, of the hair and the nails, and the laminated pavement, epithelium—in which the cells are flattened, polygonal, or fusiform, and the cell-wall is fused into one mass with the cell-contents; the contractile fibre-cells of the smooth muscles; the tubules of the lens; the prisms of the enamel; the various forms of bone-cells; and the transversely striated cells of muscular fibre.

All cells originate or are produced in the same way. Either they are developed free in vegetable or animal fluids, or they are produced in the interior of preceding cells. In all cases they originate in connection with a substance called protein, which exists in cells, either in the form of a small dark spot called a nucleus, or cytoblast, in the interior of which is a nucleolus, or of an expansion on the interior of the cell, when it is called the primordial utricle. Free cell-development has been observed to take place in plants, in saccharine and other liquids about to undergo the fermentation process, and amongst animals in the chyle, blood, and lymph. The exact mode of the development of cells under these circumstances has not been accurately observed, and the particles or granules of proteinaceous matter from which they are supposed to originate have not yet been proved to have had their origin independent of other cells. The most common form of cell-development is that in which the cell grows around or from the nucleus or primordial utricle. In the animal kingdom the development of the cell more frequently takes place around the nucleus, whilst in the vegetable kingdom its origin is more frequent from the folding in or contraction of the primordial utricle upon itself, by which means two cells originate in one.

Besides the development of cells around the nucleus and round the investing membrane, or primordial utricle, within the walls of the cell, a multiplication of cells frequently takes place by division of the whole cell. This takes place in many of the lower forms of animals and plants [PROTOZOA], and also in the red blood-corpuscles of the embryoes of birds and mammalia, and in the colourless blood-corpuscles of the tadpole. It is probable that further observation will extend our knowledge of this mode of cell-multiplication.

One of the highest problems for the physiology of the present day to solve is, the efficient causes of the phenomena of cell-development. The following propositions have been laid down by Kölliker as an attempt to follow up Schwann's idea of the analogy between chemical changes in inorganic bodies and those which occur in cells:—

1. The nucleus of the cell arises in the first place as a precipitate in an organisable fluid, and afterwards becomes consolidated in such a manner that a special investment and contents with a nucleolus appear. Its development may in this case be compared to that of inorganic precipitates, yet the constantly globular figure and size of the nuclei which are just formed, indicate some essential though not yet recognised condition peculiar to them.

2. In the development of cells by division the cell-nucleus plays exactly the same part which was previously ascribed to the nucleolus, and the occurrence of the formation of cells in this manner demonstrates that chemical conditions are not necessarily concerned therein.

3. In cell-development around portions of contents, and in the cleavage process, the nuclei also operate as simple centres of attraction upon a certain mass of blastema, and then follows the formation of a membrane upon the surface of this mass, which is most simply understood as a condensation of the blastema.

4. In the cell-development directly around the nucleus the investment with blastema is wanting, and the nucleus develops the membrane immediately around itself.

From what has been previously said, it will be seen that the cells are the active seat of the functions of both animals and plants, and the most conspicuous results of organisation takes place in consequence of their agency. They not only constitute the mass of the body, but by their agency alone all the special secretions and products of individual plants and animals are formed. The food is conveyed into the body by cells, the blood of animals is charged with cells, and the functions of locomotion and sensation are carried on by the agency of cells. Nor are these last functions peculiar to the animal kingdom. Contractility and sensibility seem to be the property of the substance (protein) of which the nucleus and primordial utricle are composed. To this substance Mr. Huxley proposes to give the name Endoplast, and thus concludes a lecture on the identity of structure of plants and animals:—

"In both plants and animals then there is one histological element, the Endoplast, which does nothing but grow and vegetatively repeat itself; the other element, the periplastic substance (the cell membrane) being the subject of all the chemical and morphological metamorphoses, in consequence of which specific tissues arise. The differences between the two kingdoms are, mainly, 1, that in the plant the Endoplast grows, and, as the primordial utricle, attains a large comparative size; while in the animal the Endoplast remains small, the principal bulk of its tissues being formed by the periplastic substance; and, 2, in the nature of the chemical changes which take place in the periplastic substance in each case. This distinction however does not always hold good, the Ascidians furnishing examples of animals whose periplastic substance contains cellulose.

"The plant then is an animal confined in a wooden case, and nature, like Sycorax, holds thousands of 'delicate Ariels' imprisoned within every oak. She is jealous of letting us know this; and among the higher and more conspicuous forms of plants reveals it only by such obscure manifestations as the shrinking of the Sensitive Plant, the sudden clasp of the *Dionæa*, or, still more slightly, by the phenomena of the *Cyclosis*. But among the immense variety of creatures which belong to the invisible world she allows more liberty to her Dryads; and the *Protococci*, the *Volvox*, and indeed all the *Algæ*, are during one period of their existence as active as animals of a like grade in the scale. True, they are doomed eventually to shut themselves up within their wooden cages and remain quiescent; but in this respect they are no worse off than the Polype, or the oyster even."

For further information on the subject of Cells, see the articles ANIMAL KINGDOM; BLOOD; HISTOLOGY; BOTANY; CILIA; TISSUES, VEGETABLE; TISSUES, ANIMAL.

(Sharpey, in Quain's *Elements of Anatomy;* Kölliker, *Handbook of Human Histology*, translated for the Sydenham Society by Huxley and Busk; Carpenter, *Manual of Human Physiology; Principles of Physiology;* Mohl, *On the Vegetable Cell*, translated by Henfrey; Schleiden, *Principles of Scientific Botany*, translated by Lankester; Schleiden, *On Phytogenesis;* Schwann, *On the Identity of Structure in Plants and Animals*, translated by H. Smith for the Sydenham Society; Quekett, *Lectures on Histology;* Hassall, *Microscopic Anatomy of the Human Body;* Todd and Bowman *The Physiological Anatomy and Physiology of Man;* Quekett, *Catalogue of the Histological Series in the Museum of the Royal College of Surgeons, London; Quarterly Journal of Microscopical Science;* and *Transactions of Microscopical Society*, vol. i.)

CELLULAR TISSUE. This name has been given to certain forms of both animal and vegetable structures. In the animal kingdom it has been applied to that tissue which is found investing and forming the basis of all others. As however this tissue is not more strictly cellular than any of the other structures of the body, and is even less cellular under the microscope than many others, this term has been abandoned by recent anatomical writers, and the term Areolar Tissue substituted. [AREOLAR TISSUE.] The term Cellular Tissue is still made use of by botanists to distinguish those parts of plants in which the cells have not united together to form continuous tubes or vessels. The whole of the tissues of plants like those of animals originate in cells, and it is somewhat difficult to fix the limitations of this term. [CELLS; TISSUES, VEGETABLE.]

CELLULARES, a term applied to the large class of plants, which have also received the names *Cryptogamia*, *Acotyledons*, *Agamæ*, *Excembryonatæ*, and *Acrogens*. [ACROGENS.] It was especially adopted by De Candolle, the primary divisions of whose system consisted of *Vasculares*, or plants with both cellular and vascular tissue, and *Cellulares*, or plants furnished with cellular tissue only. These distinctions do not hold good anatomically, and since the more prominent recognition of the fact that cellular and vascular tissue originate alike in the cell, and are but forms of the same substance, these distinctions have been less regarded.

CELLULARIA. [CELLARIÆA.]

CELO'SIA a genus of plants belonging to the natural order *Amarantaceæ*, comprehending the flowers which gardeners call Cockscombs, on account of the crested flattened appearance of their inflorescence. The calyx consists of 5 narrow sharp-pointed sepals, surrounded by some bracts of the same shape and colour as themselves. The stamens are 5, and united into a plaited cup. The capsule is membranous, 1-celled, opens by a transverse fissure, and contains two or three seeds. The leaves are always alternate. Only two species are cultivated, namely *C. cristata* and *C. coccinea*.

C. cristata, the Common Cockscomb, is said to be a native of the East Indies, but it is more probable that it came originally from either Japan or China, for it is only seen in gardens in the East Indies. It varies in regard both to stature and colour, some of the sorts being as much as two feet high, while others do not exceed six inches; in colour it is seen with deep blood-red, purple, and yellowish-white combs, the latter however is seldom cultivated now.

C. coccinea is by no means so striking a plant as the last in appearance, for it forms little or no crest, but it bears its flowers in panicled spikes. It also is said to be a native of the East Indies, and varies with purple and silvery or yellow flowers.

Nothing can be more easy of cultivation than these flowers; and they are capable of being brought to an extraordinary size by good management.

CELSIA (named by Linnæus in honour of Olaf Celsius, D.D., professor of Greek, and afterwards of Theology, in the University of Upsal), a genus of plants belonging to the natural order *Solanaceæ*. It has a 5-parted calyx, a rotate 5-lobed corolla, 4 perfect stamens, didynamous, bearded. All the species are herbs with simple or pinnate leaves, the flowers disposed in loose terminal racemes, each rising from the axil of a bract or small leaf.

C. orientalis has the lower leaves jagged, those of the stem bipinnate. It is a native of Cappadocia and Armenia.

C. sublanata, shrubby clothed with woolly tomentum, the leaves oval-oblong, obtuse, crenated, wrinkled, soft. It is now cultivated in this country, but its native district is unknown. It has sweet-scented flowers. There are several other species of *Celsia*, all of them closely resembling the species of *Verbascum*, under which genus many of them have been described.

In the cultivation of the species of *Celsia*, the seeds should be sown on a gentle hot-bed, and when the plants are large enough they should be set in separate pots, as they require the protection of a greenhouse or frame the first winter. In the second year they may be planted out about the month of May in any warm sheltered situation. They will flower and ripen their seed in the open air. *C. sublanata* and *C. parviflora* being shrubby plants should be treated as Pelargoniums or other greenhouse shrubs.

(Don, *Gardener's Dictionary*.)

CE'LYPHUS, a genus of Dipterous Insects of the family *Lauxanidæ* (Macquart). It has the following characters:—Antennæ wide apart, as long as the head, stylet rather thick and covered with fine hairs; scutellum convex, and covering the abdomen.

This genus is one of the most extraordinary of the *Diptera*, the species having more the appearance of little beetles than two-winged flies; the peculiarity is caused by the immense size of the scutellum, which covers the whole abdomen and incloses the wings when at rest.

C. obtectus is about one-sixth of an inch in length; the head is yellow; the last joint of the antennæ is black; the thorax and scutellum are of a bluish black colour with violet reflexions; the former is broader than long; the abdomen is fawn-colour, the legs and wings are yellowish, the latter with the base brown. It inhabits Java.

C. scutatus very much resembles the one just described, but is of a greenish copper-colour above and beneath; it is found in the East Indies.

C. Africanus, is a small species inhabiting Sierra-Leone.

CENCHRIS, a genus of Snakes belonging to the family of Rattlesnakes. [Crotalidæ.]

CENTAU'REA, a very extensive genus of plants belonging to the Cynaraceous division of the natural order *Compositæ*, but comprehending no species of any importance to man. It has the following characters:—The pappus in many rows, unequal, the second row largest; the anthers with papillose filaments; involucre imbricated; receptacle chaffy; the fruit attached laterally above to the receptacle.

C. Cyanus, the Common Blue-Bottle of corn fields, is sometimes cultivated for the sake of its many-coloured flower-heads. Two others, *C. moschata*, the Purple or White Sultan of gardeners, and *C. suaveolens*, Yellow Sultan, are occasionally seen among other annuals in gardens.

C. Cyanus with the following are British species:—*C. Jacea*; *C. nigra*, the Black Knapweed; *C. nigrescens*; *C. Scabiosa*, Great Knapwood; *C. solstitialis*, Yellow Star-Thistle; *C. Calcitrapa*, Common Star-Thistle; *C. Isnardi*.

CENTAURY. [Centaurea.]

CENTIPEDE. [Scolopendra.]

CENTRACION. [Squalidæ.]

CENTRANTHUS (from κέντρον, a spur, and ἄνθος, a flower), a genus of plants belonging to the natural order *Valerianaceæ*. It has a regular 5-lobed corolla with a spur, a single stamen, the fruit 1-celled, indehiscent, crowned with the limb of the calyx, expanded into a feathery pappus. The species are smooth herbs with undivided or pinnate leaves, and white or red flowers.

C. ruber, Red-Flowered Spurred Valerian, Red Valerian, has ovate-lanceolate leaves, spur much shorter than the tube of the corolla and twice as long as the germen. It is a native of Great Britain, in chalk-pits and on old walls. It has purple flowers, and attains a height of one or two feet. It has a sweet scent.

C. Calcitrapa has radical leaves, ovate, entire, the stem-leaves pinnatifid, the spur very short. It is a native of the coasts of the Mediterranean, and of the more temperate parts of France. It grows wild at Eltham in Kent, but there is little doubt of its being a naturalised plant there. The first species may have also been introduced, but it grows wild in many parts of Great Britain. Several other species are described and some are grown in gardens. They are elegant border-flowers, and will grow in any common soil, on walls or rock-work, and may be easily propagated by seed.

(Babington, *Manual of British Botany*.)

CENTRA'RCHUS, a genus of Fishes belonging to the section *Acanthopterygii* and the family *Percidæ*, and the subdivision 'with less than seven branchial rays.' In this genus the species have numerous spines in the anal fin; the tongue is furnished with a group of fine and very thickly-set teeth; the pre-operculum is entire; the angle of the operculum is divided into two flat points; and the body is compressed and somewhat oval; they inhabit the rivers of North America. The genus *Cychla* of some American ichthyologists is synonymous with the above.

CENTRINA. [Squalidæ.]

CENTRI'SCUS (Linnæus), a genus of Fishes belonging to the section *Acanthopterygii* and to the family *Fistularidæ*. The species of this genus are principally distinguished by their having a long tubular snout, from which character they have received the names of Sea-Snipes, Trumpet-Fish, &c. The body is inclining to an oblong oval form, compressed, carinated beneath, and covered with scales. The mouth is small, obliquely cleft, and devoid of teeth. There are two dorsal fins; the rays of the first (which is placed very far back) are spinous; the ventral fins are small, and situated behind the pectorals.

Centriscus Scolopax (Linnæus), the Trumpet-Fish or Sea-Snipe (known in Cornwall by the name of the Bellows-Fish), is the only species yet discovered off the British coast, where it is rare; the Mediterranean appears to be its natural locality. Its length is about five inches; the body is oval and compressed; the snout is elongated, and forms a tube which extends about an inch and a half before the eyes, which are large; the back is elevated, and the part for some little distance anterior to the first dorsal fin is straight, whence it tapers rather suddenly to the tail. The anterior spine of the first dorsal (which has but three rays) is very large and denticulated beneath; the rays of the second dorsal are soft; the anal fin is elongated; the ventrals are small, and have a depression behind them in which they may be lodged. The body is covered with hard rough scales, which are minutely ciliated on the external edge.

Young specimens of this fish are of a shining silver-like colour; the adult specimens are reddish, with the sides of the head and under parts silvery or slightly tinted with a golden hue.

There is a figure of this curious fish given in Yarrell's 'British Fishes,' and also in Donovan's 'British Fishes.'

The genus *Amphisile* of Klein is closely allied to, and was included in the genus *Centriscus* by Linnæus; the species have the back mailed with larger scaly plates, of which the anterior spine of the first dorsal fin appears to be a continuation.

CENTRO'LOPHUS, a genus of Fishes belonging to the section *Acanthopterygii* and family *Scomberidæ*. The body is elongate, covered with minute scales; teeth small and numerous; palatine without teeth; one very long dorsal fin.

C. morio, the Black Fish, has been met with though very rarely on the British coast. It is of a black colour, the fins intensely so; the under parts are of a slightly paler hue. The head is rather blunt and rounded in front, and the mouth is small; the eyes are prominent; the body is compressed, and in a specimen 15 inches long is about 3 inches deep. There is a thin elevated ridge on the back, to which the dorsal fin is attached; this fin commences before the middle of the back (viewing it from the side), and extends almost to the tail; the pectoral fins are pointed; the ventral fins are bound down by a membrane; the tail is large and forked; the body is covered with very small scales.

In Mr. Yarrell's 'British Fishes,' one specimen is described as being 15 inches long, and another "measured 2 feet 8 inches in length, and weighed 14 lbs. The skin was observed to be so tough as to be stripped from the fish like that of an eel; no air-bladder was found. The taste was delicious." They were caught off the coast of Cornwall, and the species is described as having great strength and velocity.

CENTRONO'TUS, a genus of Fishes belonging to the section *Acanthopterygii* and family *Scomberidæ*. In this genus the spines, which in most of the Acanthopterygians form the anterior dorsal fin, are free or unconnected by membrane; they have all ventral fins.

The above characters are common to a large number of species of the *Scomberidæ*, and hence it has been thought convenient to seize some minor distinctions for the purpose of dividing the genus *Centronotus* into several sub-genera. In Cuvier's 'Règne Animal' they are as follows:—Sub-genus *Naucrates*, or those in which the body is elongate; the tail carinated at the sides, and which have two free spines before the anal fin. To this sub-genus belongs the Pilot Fish (*Naucrates ductor*), which is well known for its habit of following vessels to a considerable distance in order to feed upon what is thrown overboard; and it is under such circumstances that this fish has been occasionally met with on the British coast. It is about a foot in length, and of a bluish-gray colour, with five broad bands of deep violet. Its shape is something like that of the mackerel, but less tapering towards the head and tail. The pectoral and ventral fins are of moderate size, the latter very close together; the dorsal fin commences about midway between the head and the tail, and continues almost to the latter part; anterior to the dorsal fin there are three free spines: the tail is forked.

Elacates is another sub-genus. The species have nearly the form of the one last mentioned, but differ in the head being depressed, the tail not carinated, and there being no free spines before the anal fin. The next sub-genus, *Lichia*, has free spines before the dorsal and anal fins, and the tail not carinated at the sides. In front of the dorsal spines there is a single one laid flat and pointing forwards. The *Scomber amia* of Linnæus, a large fish upwards of 4 feet in length, which inhabits the Mediterranean, belongs to this section. There are two other species known from the same locality; the one here mentioned is distinguished by the lateral line being much curved and forming an S. The last sub-genus, *Trachinotus*, differs chiefly from *Lichia* in having the profile of the body deeper, and the dorsal and anal fins longer and more tapered.

CENTROPHORUS. [SQUALIDÆ.]

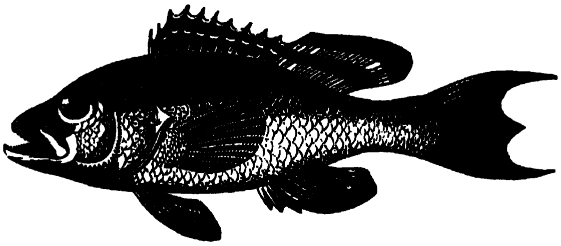
CENTROPO'MUS, a genus of Fishes belonging to the section *Acanthopterygii*, to the division Thoracic-Perches, and the family *Percidæ*. In this genus the muzzle is compressed, as in the pike, and the head, when viewed from the side, is much pointed; the lower jaw projects beyond the upper; the pre-operculum and operculum are covered with scales; the former is dentated, and the latter unarmed. There are two dorsal fins with a distinct intervening space; the anterior one has eight rays, and the posterior eleven; the teeth are very minute and crowded; the ventral fins are under the pectorals.

C. undecimalis, so named from its having eleven rays to the posterior dorsal fin, is common throughout South America, where it forms a considerable article of consumption, and is known by the name of the Sea-Pike; it frequents the mouths of great rivers, and sometimes extends its course up as far as the fresh water.

The Sea-Pike grows to a considerable size, and weighs sometimes as much as 25 lbs. The body is of rather a more elongate form than the common perch; its colour is greenish-brown above and silvery beneath; the anterior dorsal fin is gray; the other fins are yellowish, and finely dotted with black on the edges; the lateral line is black. This species is the only one of the genus known, and is the *Sciæna undecimalis* of Bloch.

CENTROPRI'STES (Cuvier), a genus of Fishes belonging to the section *Acanthopterygii*, and to the family *Percidæ*, and belonging to the division with 'seven branchial rays and a single dorsal fin.' This genus is distinguished chiefly by the species having all the teeth fine, rather strong and recurved, and closely set: the pre-operculum is serrated; and the operculum is spined.

C. nigricans, the Black Perch or Black Bass, is abundant in the rivers of the United States, and is much esteemed for the table. It is of a deep olive-green colour above, and pinkish on the under parts; the dorsal fin is bluish, with pale transverse bands; the other fins are of a deeper hue; the tail and anal fins are spotted.



Black Perch (*Centropristes nigricans*).

This species is remarkable for having the tail doubly notched, the central and two outer parts projecting. This character however is not so distinct in old individuals. The young are marked with clouded transverse bands.

There are some few other species found on the American coast. The one above described is the *Perca varia* of Mitchell.

(*Transactions of the Literary and Philosophical Society of New York.*)

CENTROPUS (Illiger), a genus of Birds belonging to the order *Scansores*. The species are natives of India and Africa. They have a long pointed thumb-nail, the same as the larks. Their plumage is rigid and spinous. They build their nests in the holes of trees, and lay white eggs. They feed chiefly on grasshoppers, and dwell amongst reeds and other herbage, and do not often take to wing. Their flesh is not pleasant eating.

CENTU'NCULUS, a genus of plants belonging to the natural order *Primulaceæ*. It has a 4-parted calyx, corolla with a subglobose inflated tube and patent 4-parted limb, 4 stamens inserted in the throat of the corolla; the capsule many-seeded, opening all round transversely. The only species of this genus, *C. minimus*, is a native of Great Britain. It is a very minute plant with a prostrate stem, the leaves alternate, ovate, acute; the flowers pale rose-colour, subsessile, without glands at the base. It grows in damp, sandy, and gravelly places, and is known by the common name of Bastard Pimpernel. (Babington, *Manual of Brit. Bot.*)

CEPHAE'LIS, a genus of plants belonging to the natural order *Cinchonaceæ*. The species are remarkable among other things for their flowers growing in close heads, and being surrounded by involucrating bracts, which are sometimes richly coloured. They are chiefly interesting from comprehending the plant which yields the Ipecacuanha Root of the druggists. This species is the *Cephaelis Ipecacuanha*, and is a native of the forests of Brazil, growing in close damp shaded places, and flowering in the months of January and February. It was also met with by Homboldt and Bonpland in the mountains of New Granada. It is a perennial plant, with a weak stem not above 2 or 3 feet long, and usually lying almost prostrate. Its roots are contorted, from 4 to 6 inches long, about as thick as a goose-quill, and separating into rings which are about half as thick as the whole diameter of the root. The leaves collect about the end of the stem or its branches, are of an oblong ovate figure, slightly hairy, from 3 to 4 inches long, and connected by deeply-lobed fringe-like stipules. The flower-heads are very small, surrounded by green bracts, and placed upon the end of a long peduncle; when in flower they are said to be erect, but they are represented as being pendulous in that state as well as when in fruit. The flowers are small and white, and are succeeded by little purple berries. The Puri and Coroado Indians chiefly collect this drug, which furnishes them with a valuable means of barter with Europeans. They gather it at all seasons of the year, principally however in January, February, and March; and the only care they take is to separate the roots from the stem, to lay them up in bundles, and to dry them in the sun.

CEPHALANTHE'RA, a genus of plants belonging to the natural order *Orchidaceæ*, and to the tribe *Limodoreæ*. It has a converging perianth, the lip interrupted, the basal division saccate, jointed to the recurved terminal one, the stigma transverse without a rostellum, the anthers terminal, erect, moveable, shortly and thickly stalked, 2-celled, the cells with imperfect septa, the column elongated, the germen sessile, twisted. Three species of this genus are natives of Great Britain.

C. grandiflora, with ovate-lanceolate or ovate-pointed leaves, bracts longer than the glabrous germen, lips obtuse, included. It has white flowers, with the lips marked with several elevated longitudinal lines. It is found in dense woods, usually on a calcareous soil.

C. ensifolia, with lanceolate-pointed leaves, bracts much shorter than the glabrous germen, lips obtuse, included. The flowers are white, the lips marked with several elevated white lines and a yellow spot in front. It is a rare plant, and found in mountainous woods.

C. rubra has lanceolate acute leaves, bracts longer than the downy germen, the lip acute, as long as the petal. The flowers are purple, the lip white with a purple margin, marked with numerous wavy longitudinal lines. A very rare plant in mountainous woods.

(Babington, *Manual of Brit. Bot.*)

CEPHALANTHUS, a genus of plants belonging to the natural order *Cinchonaceæ*, of which it is one of the most northern representatives. *C. occidentalis*, the Button-Wood, derives its English name from the round balls of flowers with which it is covered in the month of August. This plant is common in swamps, ponds, and stagnant waters, from Carolina to Canada, forming a shrub from 6 to 15 feet in height, with a light spongy wood. The inner bark of its root is an agreeable bitter, and is frequently used as a remedy in obstinate coughs.

CEPHALA'SPIS, a singular genus of Fossil Placoid Fishes, established by Agassiz on specimens from the Old Red-Sandstone of Herefordshire, Forfarshire, &c. The head covering is like the anterior part of a Trilobite. *Cephalaspis Lyellii*, and *C. Lloydii* are British species.

CEPHALO'CULUS, Lamarck's name for a genus of *Branchiopoda*, which he established for the *Polyphemus Oculus* of Müller, and which he places next to *Cyclops*. [BRANCHIOPODA.]

CEPHALO'PODA, Μαλάκια of Aristotle, *Mollia* of Pliny, *Cephalophora* of De Blainville, *Antliobrachiophora* of Gray, a class of Mollusks whose mantle, according to Cuvier, unites beneath the body, and thus forms a muscular sac which envelops all the viscera. This body or trunk is fleshy and soft, varying in form, being either sub-spherical, sub-plano-elliptical, or elongato-cylindrical, and the sides of the mantle are in many of the species extended into fleshy fins. The head protrudes from the muscular sac, and is distinct from the body; it is gifted with all the usual senses; and the eyes in particular, which are either pedunculated or sessile, are large and well developed. The mouth is anterior and terminal, armed with a pair of horny or calcareous mandibles, which bear a strong resemblance to the bill of a parrot, acting vertically one upon the other. Its situation is the bottom of a subconical cavity formed by the base of the numerous fleshy tentacular appendages which surround it, and which have been termed arms by some naturalists and feet by others.

These appendages in the great majority of living species are provided with acetabula—suckers or cupping-glass-like instruments—by means of which the animal moves at the bottom of the sea, head downwards, or attaches itself to its prey or to foreign bodies. These suckers are either unarmed or armed with a long sharp horny claw, as in *Onychoteuthis*. In the unarmed acetabulum the mechanism for adhesion is so perfect during life that, as Dr. Roget well observes in his 'Bridgewater Treatise,' "while the muscular fibres continue contracted it is easier to tear away the substance of the limb than to release it from its attachment; and even in the dead animal the suckers retain a considerable power of adhesion." The same author clearly describes the apparatus by means of which the acetabulum executes its functions:—"The circumference of the disc is raised by a soft and tumid margin; a series of long slender folds of membrane, covering corresponding fasciculi of muscular fibres, converge from the circumference towards the centre of the sucker, at a short distance from which they leave a circular aperture; this opens into a cavity which widens as it descends, and contains a cone of soft substance rising from the bottom of the cavity, like the piston of a syringe. When the sucker is applied to a surface for the purpose of adhesion, the piston, having previously been raised so as to fill the cavity, is retracted, and a vacuum produced, which may be still further increased by the retraction of the plicated central portion of the disc. Here we have an excellent description of the apparatus for 'holding on,' but the explanation stops short of showing how the operation of 'letting go' is effected. We well remember in our youth going far out with an old fisherman of Dawlish to visit his floating nets which he had laid for the pilchards. As we looked down into the clear blue water we could see that the number of fish entangled was great; but to the great discomfiture of the fisherman, who was eloquent on the occasion, almost every other fish was locked in the embraces of a cuttle-fish plying his parrot-like mandibles to some purpose. The fisherman who seemed to regard these unbidden guests as an incarnation of all evil, carried a capacious landing-net, but so quick was the sight of these Cephalopods, so ready were they in letting go and agile in darting back or sideways clear of the net, that though the greedy creatures held on to the last moment, the fisherman did not secure above three out of the crowds that had spoiled his haul. Upon mentioning this to Mr. Owen, he informed us that the muscular arrangement enabled the animal, when it was disposed to let go its hold, to push forward the piston, and thus in a moment destroy the vacuum which its retraction had produced." The same author ('Cyclopædia of Anatomy and Physiology,' article 'Cephalopoda') has stated that in the Calamary the base of the piston is inclosed by a horny hoop, the outer and anterior margin of which is developed into a series of sharp-pointed curved teeth. These can be firmly pressed into the flesh of a struggling prey by the contraction of the surrounding transverse fibres, and can be withdrawn by the action of the retractile fibres of the piston. [Teuthidæ.]

Digestive Organs.—The tongue, which is beset with horny points, lies between the mandibles, and the œsophagus widens into a kind of crop which leads to a gizzard nearly as fleshy as that of birds. To the gizzard succeeds a third stomach, which is membranous and somewhat spiral, wherein the liver, which is of considerable volume, pours the bile. The rectum opens into the infundibulum.

Respiratory Organs.—These are branchial, and the branchiæ are equal, symmetrical, and protected by the mantle under which they are concealed. The infundibulum, or funnel (entonnoir of the French), is a fleshy pipe or passage in front of the neck, through which the respiratory currents pass and the excrements are discharged. The young, as in other classes, respire more quickly than the adult. Dr. Coldstream saw an *Eledone*, one inch and a half in length, breathe eighteen times in a minute, while another of the same species, four inches in length, breathed only ten times in a minute.

Circulating Organs.—The higher organised Cephalopods present the remarkable circumstance of having three separate and well-organised hearts: one for the circulation of the arterial blood through the body, the other two for the propulsion of the venous blood through each gill or respiratory organ. Only the first of these hearts, or the 'systemic,' is present in the Pearly Nautilus, which is, according to Owen, the type of the lower order of the class. In both divisions the venous system is characterised by the glandular bodies appended to the branchial divisions of the vena cava, or main venous trunk.

Sexual Organs.—Separate and developed in distinct individuals. It is not determined whether impregnation is effected before the ova are excluded, during their exclusion, or afterwards. Cuvier was of opinion that fecundation is effected by arrosement, as in the majority of fishes. The ovary of the female is situated in the bottom of the sac. Two oviducts receive the eggs from the ovary, and carry them out across two large glands, which envelop them with a viscous substance, and unite them together into bunches like grapes.

Brain and Senses.—The brain is included in a cartilaginous cavity in the head, and gives off on each side a nervous cord, which forms in each orbit a large ganglion, whence proceed innumerable optic nervous filaments. The eye is composed of numerous membranes, and covered by the skin, which becomes transparent in front of the organ, and sometimes forms folds which perform the office of eyelids. Owen has observed that the cornea of *Rossia* is defended by a circular fold of integument, which can be completely closed by an orbicular sphincter in front of the eye—a structure which is probably required in this species in order to protect the cornea against the spicula of ice, with which its native seas abound, especially in the summer or thawing season. In the Calamary (*Loligo*) on the other hand, there is no tegumentary fold. The ear is nothing more than a small cavity hollowed out on each side near the brain, without semicircular canals or an external tube, and in this cavity is suspended a membranous sac containing a limpid fluid and a small compact stony substance or otolithe, a sort of ossiculum auditûs.

Ink-Bags.—The excretion from these bags is of a deep black, and in those species in which it occurs (for it is not common to the whole family) it is produced by a gland appropriated to its secretion, and reserved in a small bag till the exigencies of the animal call for its effusion to cloud the surrounding water in order that it may conceal itself. It has been long considered that the Indian Ink imported from China is manufactured from this secretion, but Cuvier observes that M. Rémusat has found nothing in Chinese authors confirmatory of this opinion. That it makes an excellent pigment even after having been buried for thousands of years in the earth is proved by Dr. Buckland's fossil ink, which he submitted to a celebrated painter, who immediately inquired from what colourman such good sepia might be procured.

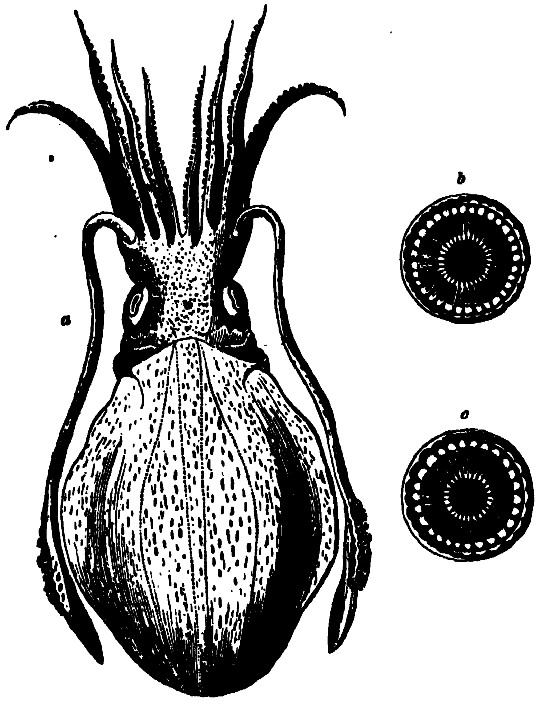
The skin of the naked species is changeable, showing spots which brighten and fade with a rapidity superior to the cuticular changes of the chamæleon.

Food.—Principally fishes and crustaceans; but there is little doubt that few animal matters come amiss to these mollusks, for they are most voracious.

Geographical Distribution.—Very wide. Hardly any sea is without some species of the family. Captain Ross discovered a new genus (*Rossia*, Owen), in the Arctic Ocean, which has since been found in our own seas. Fabricius describes two species which frequent the coasts of Greenland. ('Fauna Grœnlandica,' p. 361.)

Utility.—The flesh, especially that of the arms, is eatable, and is considered very nutritious. Though neglected in the British Islands, it is brought to table in other countries. The arms, cut into portions and prepared for cookery, are to be frequently seen in the Neapolitan market. The cuttle-bone is used for erasures, and manufactured into 'pounce' of the shops. The prepared ink is capable of being made into a pigment. That the Naked Cephalopods formed a favourite dish with the ancients, and were considered not unworthy of the most exquisite cookery, there is no doubt. (See for instance Athenæus, 'Deipnosoph.' lib. i. vi., vol. i., p. 14: lib. vii. lxxxvii. et cxxx., vol. iii., pp. 140 et 199: lib. xiv. xvii., vol. v., p. 255, Schweighäuser's edition.)

The natural division of the class is into those Cephalopods which are naked (*Cephalopoda nuda*), and those which are protected by an external shell (*Cephalopoda testacea*). Of the former, *Sepia officinalis*, the Common Cuttle-Fish, may be taken as an example; and the following cut will give a general idea of the form of a naked Cephalopod, but this varies in the different genera. In *Sepia officinalis* the soft parts are supported by a firm calcareous bone, the well-known cuttle-bone of the shops, and in all the naked Cephalopods (not including *Ocythoë*) now existing, it would appear that some rudiment at least of a bony, horny, or cartilaginous support is to be found. [Sepiadæ.]



The Cuttle-Fish (*Sepia officinalis*).

a, *Sepia officinalis*; the dotted line shows the place and shape of the dorsal piece, or cuttle-bone; *b*, the lower side of an acetabulum of *Octopus vulgaris*; *c*, of an acetabulum of *Eledone*.

The *Nautilus Pompilius* affords an example of the testaceous Cephalopods, or those which are protected by a shell. [Nautilidæ.]

Professor Owen has however shewn the necessity of dividing this order into two groups, which he proposes to call *Dibranchiata* and *Tetrabranchiata*.

The *Dibranchiata* are characterised by possessing two branchiæ; and to this division all the Naked *Cephalopoda* belong, such as the species of the genera *Sepia*, to which the Common Cuttle-Fish belongs, *Loligo*, *Octopus*, *Rossia*, and *Ommastrephes*.

The *Tetrabranchiata* possess four branchiæ; and to this division the *Nautilus* [Nautilidæ], and the bulk of the fossil species of *Cephalopoda* known under the names of *Ammonites*, *Goniatites*, *Ceratites*, &c., belong. The extinct animals of this division are by far the most numerous.

None of the *Tetrabranchiata* exist in the British seas; there are however several forms of *Dibranchiata*, of which the following synopsis from Forbes and Hanley's 'British Mollusca,' will give an idea :—

Family, OCTOPODIDÆ.
  Genus, *Octopus*. [OCTOPUS.]
    O. vulgaris.
  Genus, *Eledone.* [ELEDONE.]
    E. cirrhosus.
Family, TEUTHIDÆ.
  Genus, *Sepiola.* [SEPIOLA.]
    S. Atalantica.
    S. Rondeletii.
  Genus, *Rossia.* [ROSSIA.]
    R. macrosoma.
    R. Owenii.
  Genus, *Loligo.* [LOLIGO.]
    L. vulgaris.
    L. media.
    L. marmora.
  Genus, *Ommastrephes.* [OMMASTREPHES.]
    O. sagittatus.
    O. todarus.
    O. Eblanæ.
Family, SEPIADÆ.
  Genus, *Sepia.* [SEPIA.]
    S. officinalis.
    S. bisserialis.
  Genus, *Spirula.* [SPIRULA.]
    S. Peronii.

Fossil Cephalopoda.

These are multitudinous, and in the bye-gone ages of the world appear to have been powerful instruments for keeping down the other tribes of ancient Testaceans, Crustaceans, and even Fishes; for many of them—certain *Orthocerata* and *Ammonites* for example—afford evidence of gigantic dimensions. In the periods prior to the Chalk Formation, and at the time of its deposit, they were the agents employed for this purpose, and were succeeded in the Tertiary period by the Fossil Trachelipods, which are either entirely absent or very scarce in the Secondary and Transition series, while the Fossil Cephalopods occur but rarely in the Tertiary beds. The extinct Ammonite [AMMONITES], Baculite, Belemnite, Hamite, Orthoceratite, Turrilite, and Scaphite, will readily occur to the fossil zoologist as some of the ancient class. The *Foraminifera*, formerly placed by D'Orbigny in this class, are now no longer regarded even as *Mollusca*. [FORAMINIFERA.]

The following is M. D'Orbigny's division and arrangement of the class *Cephalopoda*, including both recent and fossil genera :—

Order A. ACETABULIFERA, Fer. and D'Orb.; DIBRANCHIATA, Owen.
  OCTOPODA. Genus, *Octopus*, Lam.; Ex., *O. vulgaris* (fig. 2506, 2507); *O. ventricosus* (2509).
    " *Eledone.*
    " *Philoxenis*, D'Orb.
    " *Argonauta*, Linn.; Ex., *A. Argo* (2530, 2532).
  DECAPODA. " *Cranchia*, Leach; Ex., *C. scabra* (2515).
  Fam. SEPIADÆ, Cuttle-Fishes. [SEPIADÆ.]
    " *Sepiola*, Lam.; Ex., *S. vulgaris* (fig. 2510); *S. stenodactyla* (2511, 2512).
    " *Rossia*, Owen; Ex., *R. palpebrosa* (2513).
    " *Sepia*, Linn.; Ex., *S. officinalis* (2519, 2520).
  Fam. LOLIGIDÆ.
    " *Loligo*, Lam.; Ex., *L. vulgaris* (2518).
    " *Sepioteuthis*, Blain., R. and F.
    " *Teudopsis*, Deslongchamps. Foss.
    " *Loligopsis*, Lam.
    " *Histioteuthis*, D'Orb.
    " *Leptoteuthis*, Meyer.
    " *Beloteuthis*, Münster.
    " *Belemnosepia*, Agassiz.
  Fam. TEUTHIDÆ, Calamaries. [TEUTHIDÆ.]
    " *Onychoteuthis*, Lichtenstein; Ex., *O. Banksii* (2516).
    " *Enoploteuthis*, D'Orb.
    " *Acanthoteuthis*, Wagner.
    " *Kalæna*, Münster.
    " *Ommastrephes*, D'Orb.
  Fam. BELEMNITIDÆ. [BELEMNITES.]
    " *Cenoteuthis*, D'Orb.
    " *Belemnitella*, D'Orb.
    " *Belemnites*, i. *Acuari.* Oolitic.
      ii. *Canaliculati.* Oolitic.
      iii. *Hastati.* Oolitic and Cretaceous.
      iv. *Clavati.* Lias.
      v. *Dilatati.* Neocomien.
  Fam. SPIRULIDÆ. [SPIRULA.]
    " *Spirula*, Lam.
    " *Spirulirostra*, D'Orb.
    " *Beloptera*, Dis.; Ex., *B. sepoidea* (2584); *B. belemnoidea* (2585).

Order B. TENTACULIFERA, D'Orb.; TETRABRANCHIATA, Owen.
  1st Fam. NAUTILIDÆ. [NAUTILIDÆ.]
    Genus, *Nautilus*; Ex., *N. Pompilius* (2521); *N. scrobiculatus* (2522).
      Fossil species. *a. Striati.*
        b. Radiati.
        c. Lævigati.
    " *Lituites*, Breyn, F.; Ex., *L. articulatus* (2581).
    " *Hortolus*, Montfort, F.
    " *Nautiloceras*, D'Orb., F.
    " *Aploceras*, D'Orb., F.
    " *Gomphoceras*, Lew., F.
    " *Gonioceras*, Hall, F.
    " *Orthoceratites*, Breyn, T.; Ex., *O. laterale.*
    " *Actinoceras*, Brom.
    " *Andoceras*, Hall.

  2nd Fam. CLYMENIDÆ. [CLYMENIDÆ.]
    * Partitions without lateral or dorsal lobes.
      Genus, *Melia*, Fischer.
      " *Cameroceras*, Conrad.
      " *Campulites*, Desh.; Ex., *C. ventricosus* (2582, 2583); *Phragmoceras*, Sow.
      " *Trochilites*, Conrad.
    ** Partitions with one lateral lobe but no dorsal lobe.
      Genus, *Clymenia*, Münster.
      " *Megasiphonia*, D'Orb.

  3rd Fam. AMMONITIDÆ. [AMMONITES.]
    * Without a dorsal lobe.
      Genus, *Oncoceras*, Hall.
      " *Cyrtoceras*; Goldfuss; Ex., *C. depressum* (2580).
      " *Gyroceras*, Meyer.
      " *Cryptoceras*, D'Orb.
    ** One dorsal lobe.
      Genus, *Stenoceras.*
    *** Partitions angular, not branched; lateral lobes, and one-angular dorsal lobe.
      Genus, *Goniatites* [GONIATITES]; Ex., *G. truncatus*, *G. Listeri*, *G. spirorbis*, *G. Gibsoni.*
        i. *Linguati.*
        ii. *Lanceolati*; Ex., *G. Henslowi* (2558).
        iii. *Genufracti*; Ex. *G. striatus* (2563).
        iv. *Serrati.*
        v. *Crenati.*
        vi. *Acutolaterales.*
        vii. *Magnosillares*; Ex., *G. sublævis* (2557).
        viii. *Nautilini*; Ex., *G. expansus* (2556).
      " *Ceratites*, De Haan; Ex., *C. nodosus* (2547).
    **** Partitions branched, one dorsal lobe.
      Genus, *Ammonites*, Brug. [AMMONITES.]
        i. Oolitic Groups.
          Arietes. Lower Lias; Ex., *A. obtusus* (2538).
          Falciferi. Upper Lias.
          Amalthei.
          Ornati. Oxford Clay.
          Capricorni.
          Coronari. Inf.-Oolite.
          Armati. Upper Oolites.
        ii. Oolitic and Cretaceous Groups.
          Heterophylli. D'Orb.
          Macrocephali.
          Fimbriati. D'Orb.
          Planulati.
        iii. Cretaceous Groups.
          Cristati.
          Tuberculati.
          Clypeiformes.
          Pulchelli.
          Rothomagenses (2548).
          Dentati.
          Flexuosi.
          Compressi.
          Anguli costati.
          Ligati.
      " *Scaphites*, Parkinson.
      " *Crioceras*, Léveillé; Ex., *C. Dewallii* (2550).

Genus, *Toxoceras*, D'Orb.
„ *Baculites*, Lam.; Ex. *B. vertebralis* (2576).
„ *Ptychoceras*, D'Orb.
„ *Hamites*, Parkinson.
„ *Turrilites*, Lam.; Ex., *T. costatus* (2577).
„ *Heteroceras*, D'Orb.
„ *Heliococeras*, D'Orb.

CEPHALOPTERA. [Squalidæ.]

CEPHALOPTERUS. [Coracina.]

CEPHALOPUS. [Antilopeæ.]

CEPHALOTA'CEÆ, a natural order of Exogenous Plants. It consists of but one genus, and that of only one species, the *Cephalotus follicularis*, Australian Pitcher-Plant. It has the following essential characters:—Calyx coloured, 6-parted, with a valvate æstivation; no corolla; stamens 12; those opposite the sepal shortest, inserted into the edge of a deep glandular perigynous disc; anthers with a thick granular connective, carpels six, distinct, 1-seeded, ovate, erect; achenia membranous, opening by the ventral suture, surrounded by the persistent calyx and stamens; seed solitary (sometimes two), erect; embryo minute, in the base of the axis of a fleshy friable somewhat oily albumen. The *Cephalotus follicularis* has small white flowers, with a simple scape, bearing a compound terminal spike; the leaves are exstipulate, and have mingled amongst them operculate pitchers. This plant, according to Labillardière, is allied to *Rosaceæ*, and, according to Jussieu, to *Crassulaceæ*. Brown places the order between *Crassulaceæ* and *Francoaceæ*. Lindley points out its relations through the last order to *Pittosporaceæ* and *Sarraceniaceæ*, where the leaves of the plants are also converted into pitchers. He also formerly placed *Dionæa* in this order, and observed that it differed little from *Cephalotus* except in the presence of petals, and in the syncarpous fruit, with the seeds collected upon a flat central placenta. He now places *Dionæa* with *Droseraceæ* and *Cephalotus* in or near *Ranunculaceæ*. [Dionæa.]

In cultivating the Australian Pitcher-Plant it should be placed in turfy peat soil either in a box or pot. It should be kept rather moist, and this may be effected by placing the pots in pans of water. The plants are always the healthier for allowing moss to grow over the surface of the soil in which they are planted. They can only be increased by seed.

(Lindley, *Natural System;* Don, *Gardener's Dictionary*.)

CEPHALOTES. [Cheiroptera.]

CEPHALOTUS. [Cephalotaceæ.]

CEPHEA. [Acalephæ.]

CEPHUS. [Colymbidæ.]

CEPHUS, a genus of Hymenopterous Insects belonging to the family *Xiphydriidæ* (Leach). It has the following characters:—Antennæ rather long, growing gradually thicker towards the apex; head transverse, joined to the thorax by a distinct and rather long neck; mandibles exserted; maxillary palpi long and slender; body somewhat compressed, especially towards the apex; ovipositor distinct, exserted.

C. pygmæus is common in flowers, particularly buttercups. It is about one-third of an inch in length; black, with two yellow fasciæ on the abdomen; the palpi and tibiæ also more or less yellow. The larva of this insect is said to live in the stems of wheat. Mr. Stephens enumerates ten British species of this genus, most of which are black, with yellow fasciæ.

CEPO'LA (Linnæus), a genus of Fishes belonging to the section *Acanthopterygii* and family *Tænioidei*. The technical characters of this genus are:—Body much elongated, compressed, and tapering gradually towards the tail, which is pointed; head (when viewed from the side) about the same width as the body; snout short and obtuse; under jaw curved upwards; teeth curved and well developed; dorsal fin extending from the head to the tail (which is pointed); anal fin extending thence nearly the whole length of the body; branchiostegous membrane with six rays.

C. rubescens, the Red Band-Fish and Red Snake-Fish, has been found on the British coasts, but is not uncommon in the Mediterranean. It is of a pale carmine colour, and varies from 10 to 15 inches in length; it is very smooth and almost destitute of scales; the body is slender, much compressed, and tapers very gradually from the head to the tail. The riband-like and compressed form of the body increases with age; the young are somewhat oval, or almost round. The pectoral fins are small; the ventrals are situated rather anterior to the line of the origin of the pectorals, and have the first ray spinous. The dorsal and anal fins both extend to and join the tail, or caudal fin (which terminates in a point), so that they form one continued fin. (Yarrell's 'British Fishes;' Jenyn's 'Manual of British Vertebrate Animals;' Linnæan 'Transactions,' vol. vii., &c., where this fish was recorded as British for the first time by Colonel Montagu.)

C. tænia (Linnæus) is said to differ from the species just described in having a row of hard points along the side of the body above the lateral line, and in having an inner row of teeth in the lower jaw: it is however very probably not a distinct species.

CERADIA, a genus of plants belonging to the Corymbiferous division of the natural order *Compositæ*. *C. furcata* is a half-succulent plant inhabiting the most sterile regions of south-western Africa. It yields in some abundance a brittle resin-like substance, which gives out a fragrant odour when burnt, and has been called African Bdellium; it is however a very different thing from the true Bdellium. [Bdellium.]

CERAMBY'CIDÆ, a family of Coleopterous Insects of the section *Longicornis* (Latreille). They are characterised by the body being generally elongate; antennæ very long, as long or longer than the body; labrum very distinct and broader than long; maxillæ with the terminal processes membranaceous and projecting; mandibles moderate; eyes lunate, partly surrounding the basal joint of the antennæ; thorax nearly cylindrical, or orbicular, truncated before and behind; legs rather long, and generally compressed; tarsi spongy beneath, penultimate joint bilobed.

The *Cerambycidæ* are found in all parts of the globe, but they abound most in hot climates, and constitute a very extensive group of coleopterous insects, the most striking feature of which is the great length of the antennæ. One of their most important functions appears to be to assist with numerous other wood-feeding insects in the removal of old and decaying trees: it is in the larva state principally that this business is performed. The parent insect deposits her eggs in a hole excavated for the purpose. When these are hatched the larvæ commence feeding upon the wood, and in so doing excavate burrows in various directions, but mostly longitudinal; in this state they frequently live for two or three years, and the perforations which they make are very extensive.

The larvæ are elongate, broadest towards the head, and taper slightly towards the tail, and are composed of 13 segments. They have 6 legs (situated one on each side, on the under part of the three anterior segments of the abdomen) which are so minute as to be scarcely apparent. They move chiefly by means of the segments of the body, which have the upper and under surfaces flat and covered with minute tubercles. In making their way in the cylindrical or (what is almost always the case) oval burrows, the animal protrudes these parts of the segments above and beneath, and thus thrusts itself forward. The head has the appearance of being composed of two segments; the hinder part is very broad (almost equalling that of the segment in which it is inserted), terminated on each side anteriorly by an angle, and separated from the fore part, which is narrow, by an elevated ridge; the jaws (mandibles) are short and very stout and strong; the antennæ are scarcely visible; the palpi are small. The first segment of the abdomen, or that next the head, is protected by a shield above of a horn-like substance.

The pupæ are what is termed incomplete, that is, when the external organs (such as the wing-cases, antennæ, legs, &c.) are each inclosed in a separate and distinct sheath, and "consequently not closely applied to the body, but have their form for the most part clearly distinguishable." The antennæ, which have been before described as being very long in the perfect insect, are bent backwards, and lie along the back of the pupa until they reach the apex of the body; they are then recurved and extend along the under side, and if very long they are again recurved, so that they, as well as all the other parts, lie close to the body.

The *Cerambycidæ* in the perfect state frequent flowers, especially the *Umbelliferæ;* the large species are often found on the trunks of trees. Different individuals of the same species vary extremely in size, a circumstance frequently observed in those insects whose larvæ feed on wood, and arising most probably from the degree of moisture or dryness of the food.

M. Latreille restricts the genus *Cerambyx* to those species which have an unequal or rough thorax, usually spinous or tuberculated, and dilated in the middle at the sides, with the third, fourth, and fifth joints of the antennæ evidently thicker than the following ones, and the remaining joints abruptly longer and thinner.

C. heros affords an example of this genus: it is about an inch and a half in length; of an elongate form, attenuated posteriorly; black; elytra with the apex pitchy, or brown; the thorax is rough and shining, and has a spine on each side. This species, together with another belonging to the same genus (*C. cerdo*), has been found in England, but it is extremely rare; in the warm and temperate parts of Europe it is common. The larva perforates the oak, and according to Latreille is perhaps the Cossus of the ancients.

The genus *Cerambyx* of Mr. Stephens and most of the British entomologists is synonymous with that of *Callichchroma* of Latreille, whereas the characters given by him for *Cerambyx* agree with those of *Hamaticherus* of English authors.

The Musk-Beetle, which is very common in the south of England on old pollard willows, will serve to illustrate the genus *Cerambyx* of Stephens's 'Illustrations of British Entomology.' It is about an inch and a half in length, of an elongate and somewhat linear form; its colour is usually bright green, sometimes blue: the under part of the body is bluish.

This insect emits a very strong and agreeable odour, which is not unlike attar of roses. It certainly bears no resemblance to musk, though those who gave it the name of Musk-Beetle appear to have thought that it did.

CERAMBYX. [Cerambycidæ.]

CERAMIACEÆ. [Algæ.]

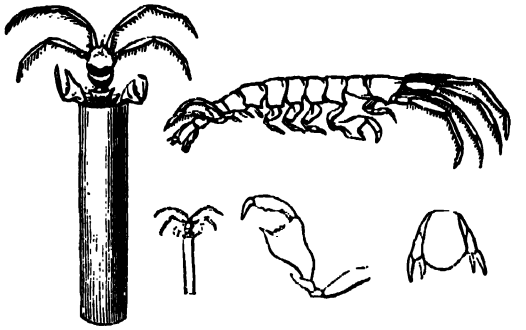
CERA'MIUS, a genus of Hymenopterous Insects belonging to the section *Diploptera* (Latreille). This genus is arranged by Latreille next to the True Wasps. It is readily distinguished by the superior wings being flat (not folded as in the wasps) and having only two cubital cells; the labial palpi are longer than the maxillæ. [VESPIDÆ.]

CERAPTURUS. [PAUSSIDÆ.]

CE'RAPUS, a genus of Amphipodous Crustaceans forming the sixth division of the third section of the order *Amphipoda* (Latreille), according to Desmarest. The following are the characters of this division:—All four antennæ very great and strong, and nearly of the same length; the upper with four joints, the lower or lateral ones with five.

Say first established this genus, which has the antennæ hairy, and performing in some sort the office of limbs, herein corresponding in a degree to the lower antennæ of the *Corophia* of Latreille. Feet of the first pair small, and terminated by a simple short nail; those of the second pair on the contrary very large, having a large, flat, triangular manus provided with a biarticulated thumb, corresponding to a well-developed point which represents the immoveable finger in the ordinary crustaceans; those of the three succeeding pairs moderate and monodactylous, and the four last longer, more slender, and directed backwards and upwards. Body long, linear, demicylindrical, composed of twelve segments, the last of which is flattened into the form of an oval plate furnished on each side with a small bifurcated appendage at the extremity. Head terminated by a very small rostrum. Eyes projecting.

Example, *Cerapus tubularis*. Like the larvæ of the *Phryganeæ* this extraordinary crustacean, which is about six lines in length, lives in a small cylindrical tube, which is considered to be that of a *Tubularia*, exposing only the head, the four large antennæ, and the two first pairs of feet. The species occurs in abundance in the sea near Egg Harbour in the United States, in the midst of *Sertulariæ*, which are supposed to form its principal food. (*Journal of the Academy of Nat. Sci. of Philadelphia*, vol. i. p. 49, pl. 4.)



Cerapus tubularis.

CERASITE, a native Chloride of Lead. It has a white, yellowish, or reddish colour, is nearly opaque, and has a pearly lustre. Its specific gravity is 7 to 7·1. It consists of lead 83, and chlorine 14. It is found in the Mendip Hills, Somersetshire.

CERASTES. [VIPERIDÆ.]

CERA'STIUM (from κέρας, a horn), a genus of plants belonging to the natural order *Caryophyllaceæ*. It has a 5-parted calyx, 5 petals, all bifid; stamens 10, 5, or 4; styles 5 or 4; the capsules tubular, opening at the end, with 10 teeth. This is an extensive genus, containing species which are common weeds in the temperate climates of most parts of the world. Don enumerates 82 species; of these 9 are British.

C. alpinum, Alpine Mouse-Ear Chickweed, has a hairy ascending stem, the leaves ovate, ovate-oblong, or lanceolate; the flowers few; the sepals bluntish, with membranous margins; bracts herbaceous, their margins often narrowly membranous; the capsules, at length, twice as long as the calyx. This plant is a native of the Pyrenees, the mountainous parts of Wales and Scotland, and of Melville Island. It is subject to great variations, and a number of varieties have been described by Brown, Bentham, and other botanists.

C. glomeratum has ovate leaves, acute lanceolate sepals, with a narrow membranous margin, and, as well as the herbaceous bracts, hairy throughout; the capsule cylindrical, ascending, twice as long as the calyx; fruit-stalks about as long as the calyx. This is a common plant in fields and on banks, flowering from April to September. The other British species are *C. triviale*, common in fields; *C. semidecandrum*, found in dry places: *C. atrovirens*, inhabiting sandy places and rocks near the sea; *C. pumilum*, found only near Croydon in Surrey; *C. tetrandrum*, found at Tynemouth and Shetland; *C. latifolium*, a rare plant; and *C. arvense*, abundant in chalky and gravelly places.

A few of the species, as *C. tomentosum*, *C. grandiflorum*, and *C. Dahunicum* are worth cultivating as border flowers. *C. latifolium*, *C. alpinum*, and *C. glaciale* are adapted for growing on rock-work, or in small pots, when they should be placed in a mixture of loam, sand, and peat. They require the same general treatment as most hardy plants. The annual species may be propagated by sowing seed in an open border in the spring; the perennial, by dividing the plants at the root.

(Don, *Gardener's Dictionary*; Babington, *Manual*.)

CE'RASUS, a genus of plants belonging to the Amygdaleous division of the natural order *Rosaceæ*, and including the Common Cherry among its species. It is hardly different from *Prunus*, there being little or nothing to distinguish it beyond its leaves when young being folded flat instead of being rolled up. Botanists seem however pretty well agreed in looking upon the Cherries as a genus distinct from Plums, and we follow their example. The species may be divided into the True Cherries, the Bird-Cherries, and the Cherry-Laurels.

Section I. True Cherries. Flowers growing in Umbels or singly, or occasionally in short Corymbs; usually appearing earlier than the Leaves.

1. *C. Avium* (*Prunus Avium*, Linn.), the Wild Cherry. Flowers appearing with the leaves, which are pale and rather downy underneath. Branches when young weak and spreading. Fruit roundish, with a soft flesh and an austere juice. A native of the woods of Europe and the west of Asia; and in a cultivated form common in gardens. In this country it occurs as far to the north as Ross-shire, where it exists in the form of a dwarf bush propagating itself rapidly by the roots. The wood is remarkable for the large size of its medullary processes, which give its longitudinal section a bright satiny lustre, and render it well suited for ornamental cabinet work. In this respect it is much superior to the *C. vulgaris*. When growing in gravelly or sharp sandy situations with a dry bottom, which are the only localities where it thrives, it acquires a very considerable size, occasional specimens being spoken of as much as 80 feet and more in height; it is however more commonly seen in the state of coppice wood. To this species we presume all the weeping or weak-branched cultivated cherries with an acid juice are to be referred either as genuine varieties or hybrid forms; such are the Merise or Merisier, Morello, Kentish and All Saint, or Overflowering Cherry, which last is often made into a species by systematic writers, and called *C. semperflorens*. Some of the varieties, especially the Double-Flowered French, as it is commonly called, the Double Merisier of the French, are remarkable for their elegance and beauty. *C. Avium* is the *Cerasus sylvestris* of Ray; and the *C. marasca*, or Marasche Cherry, of Dalmatia, from which maraschino is prepared, has no specific marks to distinguish it.

2. *C. vulgaris* (*Prunus Cerasus*, Linn.), the Common Cherry. Flowers appearing earlier than the leaves, which are light green and smooth underneath. Branches when young stiff and erect. Fruit roundish or heartshaped, succulent, more or less firm, and sugary. Found wild in the woods of Asia Minor, where it acquires a very large size. Walsh speaks of it as being still common along the northern coast of Asia Minor, whence the 'original cherry' was brought to Europe. One variety is chiefly seen in gardens, the other grows in woods in the interior, particularly on the banks of the Sakari, the ancient Sangarius. The trees attain a gigantic size; they are ascended by perpendicular ladders suspended from the lowest branches. Walsh measured one of them 5 feet in circumference (?), 40 feet to the origin of the lowest branches, and from 90 to 100 feet in full height; this large tree was loaded with delicious, fine, transparent, amber-coloured fruit. Dr. Royle considers the cherry wild in Cashmere. It was introduced into Europe by the Romans under Lucullus, about half a century before the birth of Christ, and has ever since formed one of the most esteemed varieties of dessert fruit. It differs from the genuine form of *C. Avium* in the characters above assigned to it, as also in its wood having such small medullary processes that nothing like a satiny appearance in it is produced, whatever the direction be in which it is cut; hence its grain is plain, and it is but ill suited for cabinet-makers' work. It is to be presumed that this exotic species is the origin of the sweet large cherries called Bigarreaus, Guignes, and the like, to which must undoubtedly be added the Tartarian Cherries of the English gardens. That the two species now enumerated were really distinct in the beginning we have little doubt; but long cultivation and their intermixture by hybridising, either intentional or accidental, have so confused them that the gardens are filled with intermediate races, and their limits are lost sight of.

It is here that the *C. juliana* and *Duracina* of modern botanists have to be referred; while their *C. caproniana*, or acid succulent cherries, are probably hybrids. [CHERRY.] For a full account of these species see Loudon's 'Aboretum Britannicum.'

3. *C. chamæcerasus*, the Ground-Cherry. Flowers in umbels, either with the leaves or earlier. Leaves obovate-lanceolate, shining, crenated, quite smooth, with few or no glands. Fruit spherical, acid, with stalks longer than the leaves. A dwarf species, never rising above 3 or 4 feet high, and in the gardens usually budded on the common cherry at the height of 5 or 6 feet from the ground. It is not ornamental, and is seldom seen. Its native situations are stony, rocky, mountainous places, about the skirts of woods and in hedges in the eastern parts of Europe and west of Asia; it is common in Lower Austria and Hungary. Gmelin met with it in Siberia, and Ledebour in the Kirghis Desert, near Karkaraly, in the Altaï.

4. *C. nigra*, the Black American Cherry. Flowers in sessile umbels, appearing before the leaves; light pink. Leaves obovate-oblong or

obovate-lanceolate, often cuspidate, somewhat doubly serrated, with or without two glands at the base, slightly rugose. Segments of the calyx toothed. Native of the northern states of the North American Union, and extending into Canada and Newfoundland. It forms rather a handsome tree, with its loose umbels of pinkish flowers. The fruit is as large as a moderately-sized cherry.

5. *C. Pennsylvanica*, Pennsylvanian Cherry. Flowers in sessile umbels, appearing along with the leaves. Leaves ovate or oval, sharp-pointed, smooth, and rather shining, with minute unequal toothings. Segments of the calyx toothless. A native of the more northern parts of North America, especially in Canada, where it is common. It forms a small tree, very like *C. nigra* in some respects, but differing from that species in its much smaller colourless flower and smooth rather shining leaves, which never acquire the obovate figure so common in *C. nigra*. The fruit is that of a bird-cherry, and is said to be sweet. *C. borealis* is considered by Sir William Hooker as being identical with this. It is represented in the southern states of the American Union by *C. umbellata*, which appears to differ chiefly in having spinous branches, more finely serrated leaves, and downy calyxes.

6. *C. serrulata*, the Fine-Toothed Cherry. Leaves oblong-lanceolate, obtuse at the base, tapering to the point, bordered with fine bristle-pointed teeth, thin, and not shining. A native of China, and only known in our gardens with double flowers. These are exceedingly delicate and beautiful, but they appear at so early a season as to be liable to injury from the spring frosts.

7. *C. pseudocerasus*, the Chinese Cherry. Flowers in hairy loose corymbs, appearing before the leaves, with a long hairy tube to the calyx. Leaves ovate or obovate, cuspidate, doubly serrated, slightly downy on the veins. A Chinese species, probably from the northern provinces of that great empire. It bears a small pale-red sweet fruit, which is more readily forced than that of the Common Cherry.

8. *C. depressa*, the Sand-Cherry. Flowers appearing a little earlier than the leaves, or about the same time, in small compact umbels. Leaves obovate-lanceolate, serrated, glaucous on the under side, bluish-green and somewhat shining on the upper. Fruit mucronate. A small bush resembling a dwarf almond, covered with profusion of small white flowers in May, and afterwards with small, black, bitter, shining, sharp-pointed fruit. It is found in Canada and the northern part of the United States.

9. *C. prostrata*, the Spreading Cherry. Flowers solitary, or few in a cluster, appearing along with the leaves, than which they are shorter. Leaves roundish-ovate, loosely hairy beneath, deeply and simply serrated. Calyx-tube oblong, segments downy inside. A small prostrate bush, found on the sea-coast of Candia, and on the mountains of Dalmatia and Asia Minor.

10. *C. Japonica*, the Dwarf-Almond. Leaves ovate-lanceolate, very much tapering to the point, finely serrated, slightly downy beneath, very rugose. Flowers appearing a little before the leaves in small dense clusters. Calyx smooth, bell-shaped, with the segments as long as the tube. A native of Japan, and long known in our gardens as the Double Dwarf-Almond, one of the most beautiful objects that appear in the month of March.

Section II. Bird-Cherries. Flowers growing in long Racemes, appearing with or later than the Leaves. Leaves deciduous.

11. *C. Mahaleb*, the Perfumed Cherry. Leaves roundish ovate, deciduous, glaucous on the underside, simply serrated. Flowers in somewhat corymbose racemes not much longer than the leaves. A shrub or small tree, remarkable for the powerful and agreeable odour of its flowers. It is a native of rocks in the Tyrol, Dalmatia, Carniolia, and Hungary, spreading into Asia till it acquires its most eastern limits in the woods and hedges of the southern parts of the Crimea. It is not a particularly ornamental plant, and though perfectly hardy is seldom seen in our gardens. The fruit is black, and nauseously bitter.

12. *C. Padus* (*Prunus Padus*, Linn.), the Common Bird-Cherry. Leaves oblong, cuspidate, rugose, simply serrated, deciduous. Flowers in racemes much longer than the leaves. A common species, wild in the woods and hedges of the middle parts of Europe, less common in the south, and occurring on the mountains of Caucasus and the Altaï. It is readily known by its deciduous rugose leaves, long racemes of white flowers, and round bitter fruit, which is however agreeable enough to birds. It is a native of Great Britain.

13. *C. Virginiana*, the Choke-Cherry. Leaves ovate or oblong-lanceolate, acuminate, serrated, flat, very smooth, shining, deciduous. Racemes long, cylindrical, lateral. In all systematic books are named two American Bird-Cherries, *C. Virginiana* and *C. serotina*, to each of which are assigned characters that comprehend so little of a discriminative nature that we find it impracticable to ascertain whether two species have really been before the writers on these subjects, or whether they have not distinguished under different names specimens of one and the same species. *C. Virginiana* with the above characters forms a large tree, according to Michaux, in the southern states, attaining from 80 to 100 feet in height. It is the Tawquoy-Meenahtik of the Crees, according to Sir John Richardson, rising on the sandy plains of the Saskatchewan to 20 feet, but extending as far north as the Great Slave Lake (62° N. lat.), where it attains the height of 5 feet only. Its fruit is not very edible in a recent state, but when dried and bruised it forms an esteemed addition to pemmican. Elliott adds that its timber is among the best in the United States for cabinet-makers' work. In this country it forms rather a graceful though roundish headed tree from 20 to 30 feet high, and its shining though deciduous leaves give it almost the appearance of an evergreen.

14. *C. serotina*, the Late Bird-Cherry. Leaves obovate-lanceolate, acute, serrated, channeled, very shining, deciduous. Racemes long, cylindrical, lateral. What is thus designated in this place is a plant with something of the aspect of a Portugal Laurel, and as it flowers later than the last its fruit is not usually ripened in this climate. It is principally distinguished by its leaves being more obovate, never flat, but always half-folded up, and with a more shining surface.

15. *C. Capollim*, Mexican Bird-Cherry. Leaves ovate-lanceolate, acuminate, serrated, flat, shining, deciduous. Racemes terminal. A native of the mountains of Mexico.

Section III. Laurel-Cherries. Flowers growing in long Racemes, appearing with the Leaves. Leaves evergreen.

16. *C. Caroliniana*, the Carolina Laurel-Cherry. Leaves oblong-lanceolate, acute, serrated, and entire, evergreen. Racemes lateral, much shorter than the leaves. It is a native of Carolina, and a very uncommon species in the collections of this country. It is said to be one of the most ornamental of the trees of Carolina. Its leaves are very poisonous.

17. *C. lauro-cerasus*, the Common or Broad-Leaved Laurel (cherry). Leaves oblong-lanceolate, remotely serrated, somewhat convex, pale green, evergreen. Racemes shorter than the leaves. This valuable and common evergreen, which now gives half their richness to the varied pleasure-grounds of Great Britain; which is so hardy that no frost seems to affect it; which is equally capable of resisting the greatest heat and drought of summer, and which will flourish either in the most exposed or the most shaded situations; is a native of the country near Trebizond in Asia Minor, and was sent from Constantinople to Ecluse in the year 1576 by the imperial ambassador Ungnad. Ecluse gives an interesting account of the difficulty he had in establishing the first plant, which must have been transmitted at no small charge; for it is stated to have been six feet high, with a stem as thick as a man's arm. (Clausii, 'Historia Plantarum,' p. 5.) A variegated and a barren-leaved variety are known in gardens, but the original kind is the only one worth cultivating as an object of ornament. It is multiplied in the nurseries by layering, cuttings, and seeds. This species is remarkable for the abundance of hydrocyanic acid secreted in its leaves.

18. *C. Lusitanica*, the Portugal Laurel (cherry). Leaves ovate-lanceolate, acuminate, concave, dark green, glandless, shining, evergreen. Racemes lateral, longer than the leaves. A native of Portugal, and also found in the Canaries, where it is called Hixa, acquiring a height of 60 or 70 feet. According to some the Hixa is a distinct species; Mr. Barker Webb found that plant on the Serra de Gerez in Portugal of the height just stated, while the true *C. Lusitanica* was not above 18 or 20 feet high. This is less hardy than the preceding; it is less easy to transplant, and will not grow so well under other trees; nevertheless it is one of the most useful of our naturalised evergreens. It produces fruit in abundance in England, from which it is readily propagated.

CERA'TINA, a genus of Hymenopterous Insects of the section *Mellifera* and family *Apidæ*. It has the following characters:—Exterior palpi 6-jointed, interior 2-jointed; antennæ inserted in a little fossula, and terminated almost in an elongated club; mandibles sulcated, and tridentate at the apex; abdomen somewhat ovate, elongate, narrower towards the base, and destitute of a ventral scopa.

This genus is included in the section *Apis* (xx. *d.* 2 *a.*) of Kirby's 'Monographia Apum Angliæ.'

C. cærulæa (*Apis cyanea*, Kir.), a little bee, which is very uncommon in this country, and found during the autumn in the flowers of the *Jacobææ*, will serve as an illustration of this genus. It is about a quarter of an inch in length, of a bluish-green colour, and very smooth and shining; the fore part of the head in the male is white.

Spinola states that the female *Ceratina* selects the dead branches of the bramble and likewise those of the sweet briar, and with her mandibles excavates the pith, till a cylindrical burrow of considerable length is formed; this is then divided generally into eight or nine cells, by partitions formed of the pith which was dislodged, mixed with a glutinous secretion. In each cell, as it is formed, an egg is deposited; it is then furnished with a portion of honey, which serves for the food of the larva when disclosed. The account is given under the name of *Ceratina albilabris*, which is said to be synonymous with the one above mentioned. He also says that the insect is common in the south of Europe.

(*Annales du Muséum d'Histoire Naturelle*, vol. x.)

CERATI'TES, a subdivision of the *Ammonitidæ*, as proposed by Haan. It is peculiar to the Muschelkalk. [GONIATITES.]

CERATO'NIA, a genus of Apetalous plants belonging to the natural order *Leguminosæ*. *C. Siliqua*, St. John's Bread, or the Carob-Tree, is a remarkable plant, found wild in all the countries skirting the Mediterranean, especially in the Levant. At Malta it is almost the only tree that grows, relieving the irksomeness of the white stone inclosures by its dark foliage. The pods contain a sweet nutritious pulp, and are sometimes seen in the fruiterers' shops in London; they are a common article of food in the countries where the tree grows wild. Pliny calls it *Siliqua prædulcis.* "At the present day it is sent from Palestine to Alexandria in ship-loads, and from thence across the Mediterranean, and as far as Constantinople, where it is sold in all the shops. The pulp resembles manna in taste and consistence, and is sometimes used as sugar to preserve other substances. But the circumstance that has rendered it famous is the controversy whether it was not the real food of St. John in the wilderness. Some of the fathers assert that the ἀκρίδες, or locusts, of St. John were some vegetable substance; and the μέλι ἄγριον, wild honey, the saccharine matter of this pod. It is certain that the plant grows in great abundance in the wilderness of Palestine, where its produce is at this day used for food. It is called by the Arabs kharoob." (Walsh.) The Spaniards call it Algaroba, and give its pods to horses. The seeds, which are nearly of the weight of a carat, have been thought to have been the origin of that ancient money-weight.

Carob-Tree (*Ceratonia Siliqua*).

CERATOPHRYS. [AMPHIBIA.]

CERATOPHYLLA'CEÆ, *Hornworts*, the Ceratophyllum Tribe, a small and obscure group of plants comprehending the single genus *Ceratophyllum*, probably a mere section of *Urticaceæ*, with the structure and habit of that natural order modified by the submersed situation in which the species live. It has also been supposed to have relations with *Conifera*, *Haloragaceæ*, and *Naiadaceæ*. They are aquatic plants, with cellular leaves split into capillary divisions, with monœcious flowers, a many-parted inferior calyx, several stamens, a 1-celled ovary with a pendulous ovule, and a seed whose embryo has four cotyledons surrounding a highly developed many-leaved plumula. *Ceratophyllum submersum* and *C. demersum* inhabit ditches in this country. Four other species are described. Schleiden says there is but one species.

CERATOPHYTA. [POLYZOA.]

CE'RBERA, a genus of plants belonging to the natural order *Apocynaceæ*, contains among other poisonous species that from which the Tanghin poison of Madagascar is procured. The genus *Cerbera* is known by the calyx being leafy, the corolla funnel-shaped, with a clavate tube, and five scales on its orifice, the stamens sessile just below the orifice of the tube, and a 1- or 2-seeded drupe, with a fibrous woody stone.

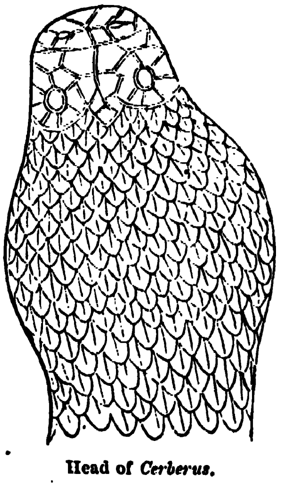
C. Tanghin, the Tanghin, is described as a tree with lanceolate alternate leaves, of a leathery texture, pale-pink flowers arranged in corymbose panicles, with a crimson star-like blotch at the orifice of the tube, and an oval drupe as large as a peach, of a green colour stained with purple, and not unlike some sorts of mango. The following interesting account of the plant is given by Mr. Telfair:— The kernel of the fruit must be a very powerful poison: it is not much larger than an almond, and yet is sufficient to destroy above twenty persons. Radama, the late king of Madagascar, abolished the use of it as an ordeal. Whether the custom has been revived by the new government I know not. It was with great difficulty that the chieftains could be persuaded to admit of the abolition of an usage which had existed from time immemorial, and whose unerring efficacy in the detection and punishment of crime had never been questioned, until Mr. Hasty, our government agent, had acquired such an influence with Radama and his court as to admit of the exposure of its fallacy. But this was the work of years; and although Radama was at length himself convinced that nothing could be more unjust than the continuance of the practice, he dared not so far shock the prejudices of his people as to order that it should cease. Even the chief performers in the ceremony, the Skids, as they are called at Tanararissoo, who unite in their own persons the offices of priests and physicians, and who administer the poisonous kernel to the victims, never doubt its power of revealing guilt or clearing innocence. The last occasion on which it was practised in Radama's reign, and of which he availed himself to effect its discontinuance, personally regarded his court and attendants. The king was affected with a complaint of the liver, for which the skid prescribed some inefficacious remedies, and as the disease became worse Mr. Hasty gave him some calomel in doses which he had found by experience to relieve himself under similar symptoms. The disease disappeared, but ptyalism was produced, and alarmed the king's family, who believed that he was poisoned, and insisted that all his immediate attendants should be put to the ordeal of the tanghin; and the royal skid was most earnest in pressing to have it performed, although he himself from his rank and place was among the first to whom it would be administered. In vain the king protested that he felt himself cured, and that the indisposition and soreness of the mouth was caused by the medicines that had relieved him, and which would pass off in a few days. The skid insisted, the ministers and principal chieftains joined with the family in requiring the ordeal, to which the king in spite of his convictions was compelled to consent; but at the same time he made it a condition that this should be the last exhibition of the kind, and he bewailed the necessity which deprived him of so many attached dependants whose fate he had predicted, while he protested his conviction of their innocence.

The king's servants, including the skid, were more than twenty in number; they were shut up at night separately, and not allowed to taste food; the next morning they were brought out in procession and paraded before the assembled people; the presiding skid had the tanghin fruit in readiness; after some prayers and superstitious evolutions he took out the kernel, which he placed on a smooth stone, and with another stone broke down part of it into a soft white mass like powdered almonds. The victims were then brought separately forward, each was questioned as to his guilt, and if he denied, his arms were tied behind, and he was placed on his knees before the skid, who put a portion of the pounded kernel on his tongue and compelled him to swallow it. Thus the kernel was shared among all the king's personal servants. On some of the individuals the poison began to operate in half an hour or less. The skid takes particular notice how they fall, whether on the face, to the right or left hand, or on the back, each position indicating a different shade of guilt. Convulsions generally come on accompanied with efforts to vomit. Those whose stomachs reject the dose at an early period usually recover. On this occasion there were only two individuals with whom this was the case. The others were thrown in a state of insensibility into a hole, and every person present at the ceremony was obliged to throw a stone over them, so that their burial was quickly completed. The king's skid was one of the first that fell. Those that recover are supposed to bear a charmed life ever after, and are respected as the peculiar favourites of the gods. ('Botanical Magazine,' fol. 2968.)

The plant which yields the Tanghin has been called by Du Petit Thomas *Tanghinia venenifera*. *C. Manghas* is a native of Singapore and some of the adjacent islands. The seeds are emetic and poisonous, whilst the milky sap is purgative. The leaves and bark are used as a substitute for senna.

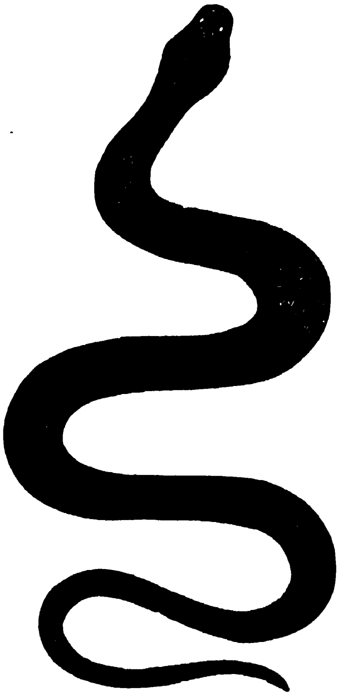
CE'RBERUS, a genus of Snakes, established by Cuvier in his division of the great genus *Coluber*. In Dr. Gray's arrangement of the Snakes of the British Museum, it is placed amongst the *Hybridæ*. The *Cerberi* like the *Pythons*, next to which they are placed in the 'Règne Animal,' have nearly the whole of the head covered with small scales, and plates only between and before the eyes; but they are without the hooks or nails near the vent. Cuvier further says that they have also sometimes simple plates at the base of the tail, but observes that whilst he has seen this arrangement in one individual, he has remarked others of the same species which had them all double; a proof in his opinion of the small importance of the character.

C. cinereus (*Coluber Cerberus*, Daudin), the Karoo Bokadam. Russell, who gives the native name above stated, thus describes the species:—



Head of *Cerberus*.

"Abdominal scutæ 144, subcaudal squamæ 59. The head somewhat broader than the neck, yet appears small in proportion to the trunk; a little convex above, compressed on the sides, and projecting into a short, obtuse, or subtruncate snout, on which the eyes and nostrils are situated. The snout is covered with small laminæ of various forms; the rest of the head with small suborbicular carinated scales. The mouth not large, the jaws nearly of equal length. The teeth close set, regular, small, reflex; a marginal and two palatal rows in the upper jaw. The eyes vertical, small, orbicular, protuberant, each situated in the centre of a remarkable circle of small triangular laminæ. The nostrils very small, vertical, near to each other, and close to the apex of the rostrum.



The Karoo Bokadam (*Cerberus cinereus*).

"The trunk thick, round, covered with large carinated, broad-oval, imbricate scales. The length 3 feet 4½ inches; thickness near the head about 3 inches; the middle of the trunk 4½ inches. The tail measures only 8 inches, is a little compressed, tapers moderately, and terminates in an obtuse point.

"Part of the head is almost black; the colour of the trunk and tail a very dark gray; the throat, belly, and under part of the tail are of a dusky yellow; but the colour of the scuta seemed to have been changed by the spirits."

Dr. Russell further observes that his specimen from which our figure is taken was sent from Ganjam in July, 1788, and that he never saw one alive. He adds that notwithstanding its suspicious appearance, the want of poison organs shows that the snake is not formidable.

C. acutus, the Bornean Bokadam, is a native of Borneo.

C. unicolor, the Philippine Bokadam, is a native of the Philippines.

C. Australis, the Australian Bokadam, is a native of Australia.

CERCARIA. [INFUSORIA.]

CERCERIS. [HYMENOPTERA.]

CERCIS, a genus of plants belonging to the natural order *Leguminosæ*. *C. siliquastrum*, the Judas-Tree, so called from the tradition that it was upon a plant of it, near Jerusalem, that the betrayer of our Saviour hanged himself, is a leguminous tree common on the shores of Asia Minor and in all the East. Dr. Walsh speaks of it as abounding in the Levant at the present day, clothing the shores of the Bosporus and the sides of Mount Libanus. It is very beautiful in all its stages. Very early in spring flowers of a bright pale red burst out before any leaf appears, not only from every part of the branches but from the trunk, piercing the thick strong bark nearly down to the root in a very remarkable manner, and it is for this reason called Red Bud. These buds are gathered and used with other raw vegetables by the Greeks and Turks in salads, to which they give an agreeable colour and taste. It is very common in England, where it proves quite hardy, but it does not flower well unless in a very sheltered situation, or when trained to a wall. There is a pale almost white-flowered variety, and also an American species (*C. Canadensis*), but neither is worth cultivation.

CERCOCEBUS. [SIMIADÆ.]

CERCOMYS. [RODENTIA.]

CERCOPITHECUS. [SIMIADÆ.]

CEREBELLUM. [BRAIN.]

CEREBRUM. [BRAIN.]

CERE'OLITE, a native hydro-silicate of Magnesia and Alumina. It occurs in globules, in Wacke, or Toadstone, and appears to result from its decomposition.

CEREOPSIS, a genus of Birds established by Latham, and placed by him (1802) among the Waders (*Grallatores*); and (in 1824) next to the Swimmers—*Palmipedes* (*Anseres*, Linn.). The characters of this bird, which Mr. Bennett says has been observed by nearly all the navigators who had visited the south coast of Australia and its neighbouring islands from 1792 downwards, are as follows:—

Bill short, elevated, obtuse, covered by a broadly expanded cere, except at the extremity, which is somewhat vaulted and truncated. Nostrils large, situated about the middle of the bill, and open. Feet with tarsi (shanks) longer than the middle toe, and bare of feathers a little way above the knees; great toe articulated to the posterior part of the tarsus; anterior toes palmated, and furnished with membranes deeply notched or cut out as it were so as to appear scarcely to reach beyond the half of their length; nails long and strong; wings ample; wing-coverts nearly as long as the quills; first quill a little shorter than the succeeding ones. Tail feathers sixteen.

C. Novæ Hollandiæ, the Cereopsis Goose, is about the size of the common goose and nearly of the same carriage, with the exception of the length of the legs. Temminck gives the length at from 2½ feet to 3 feet. We select Mr. Bennett's description:—"A broad patch on the top of the head is of a dull white, and the rest of the plumage of a dingy gray, deeper on the upper than on the under parts, having the extremity of each of the feathers of the back margined with a lighter band, and most of the wing-coverts and secondary quill-feathers marked with rounded dusky spots of from two to four lines in diameter. On the feathers of the back and shoulders the spots are much larger, assume an angular or semilunar form, and approach more nearly the general colour of the plumage. The quill-feathers both of the wings and tail are dusky black throughout the greater part of their extent. The naked extremity of the bill is black; the broadly expanded cere of a light straw or lemon colour; the irides light-hazel; the naked part of the legs reddish-orange; and the toes, together with their web and claws, and a streak passing for some little distance up the fore part of the leg, black."

Mr. Yarrell having examined one that died in the Zoological Gardens, Regent's Park, states that its trunk was much shorter than that of the true geese, and more triangular in its shape. The pectoral muscles were large and dark-coloured. The trachea was of large but nearly uniform calibre, without convolution, and attached in its descent to the right side of the neck, as in the heron and bittern. In the form of its bone of divarication and bronchiæ, it most resembled the same part in the geese. The muscles of voice were two pairs; one pair attached to the shafts of the os furcatorium, the other to the inner lateral surface of the sternum. The lobes of the liver were of large size, morbidly dark in colour; their substance broke down under the finger on the slightest pressure. The stomach, a true gizzard, was of small size as compared with the bulk of the bird. The first duplicature of intestine was 6 inches in length, at the returning portion of which the biliary and pancreatic ducts entered; from thence to the origin of the cæca 4 feet 6 inches; the cæca 9 inches each; the colon and rectum together 5 inches; the whole length of the intestines was 7 feet 5 inches. The stomach and intestinal viscera were loaded with fat.

With regard to its habits Mr. Bennett says—"It is true that the limited opportunities that have occurred of observing it in a state of nature have precluded the possibility of obtaining a complete history of its habits and mode of life; but the accounts furnished by various writers lead directly to the inference that it resembles the wild geese of the northern hemisphere as closely in these particulars as in general conformation. We cannot state with certainty whether it is equally migratory; but Captain Flinders, who found it at one period of the year so abundant on Goose Island as fully to justify the appellation, adds that it was by no means so numerous at a different season, and this fact necessarily implies at least a partial change of locality. In its manners it appears that it is by no means so shy as our northern geese, a circumstance which probably depends on the little disturbance that it has hitherto met with in its native haunts. Labillardière tells us that many of those first seen by him suffered themselves to be taken with the hand; but the rest becoming apprised of their danger speedily took to flight. Considerable numbers were taken by the crew of Captain Flinders's vessel, both at Lucky Bay and Goose Island, by knocking them down with sticks, and some of them were secured alive. According to M. Bailly, those seen by him at Preservation Island evinced so little shyness, and suffered themselves to be approached so readily, that his boat's crew were enabled to procure

Cereopsis Goose (*Cereopsis Novæ Hollandiæ*).

without any trouble a sufficient quantity to victual them during their stay. The flesh of these geese, as they are called, is described by Bass as being excellent. D'Entrecasteaux considered it much more delicate than that of the European goose; and Flinders adds that on Preservation Island it formed the best repasts of his men.

"It would seem that this bird does not often leave the coast to visit the interior of the country, for M. Riche, who was lost by his companions for more than two days at Espérance Bay, never met with it in the course of his wanderings in search of them. M. Bailly states that on Preservation Island it takes up its abode on the grassy declivities; and Captain Flinders found it on Goose Island, amongst the grass and on the shore: 'It feeds,' he says, 'upon grass, and rarely takes to the water.' Its usual weight is from 7 to 10 lbs. According to Mr. Bass it has a deep, hoarse, clanging, and though a short yet an inflected voice; and to the accuracy of this observation we can ourselves bear testimony."

This bird has lived and bred in the Gardens of the Zoological Society in Regent's Park, where there are at present several living specimens. Our drawing is from a pair with a brood hatched in the Gardens.

CE'REUS, a genus of plants belonging to the natural order *Cactaceæ*. It is characterised by its sepals being very numerous, imbricate, adnate to the base of the ovarium, united into an elongated tube, outer ones shorter and like a calyx, middle ones longer and coloured, innermost ones petaloid; the style multifid at the apex; the berry areolate, tubercular, or scaly from the remains of the sepals. The species are fleshy grotesque shrubs, with a woody axis and soft interior. They possess angles which are vertical and covered with bundles of spines. The flowers are large, arising from the angles of the spines. They are called Torch-Thistles.

C. senilis, the Old Man Torch-Thistle, is an erect plant, having a stem with 20-25 vertical ribs, covered with fascicles of bristles, each fascicle containing from 15-20 radiating hair-formed curled bristles. Its long gray bristles give it the appearance of the head of an old gray-haired man. It is a native of Mexico.

C. flagelliformis, the Creeping Cereus, has prostrate stems with about 10 angles. It is very common in our gardens, and its trailing stems require the support of trellis-work. It bears an abundance of beautiful red and pink flowers. It is a native of South America, though now naturalised in Asia and Africa.

C. grandiflorus, the Night-Flowering Cereus, has rooting stems, with 5 or 6 angles and fascicles of bristles, with 5-8 in each fascicle. It is a native of the West India Islands, and is found in many parts of the mainland of South America. This plant when cultivated produces very large beautiful sweet-scented flowers. They are however of short duration, remaining open not more than six hours. They generally begin to open between seven and eight o'clock in the evening, and are fully expanded by eleven or twelve, and before the next morning they are quite faded.

C. speciosissimus is an erect plant, 3-4 angled, the angles toothed, the prickles subulate, straight, rising from a white tomentum. It is a native of Mexico, but is very commonly cultivated in our gardens, on account of its large flowers, which are of a beautiful scarlet, the inner petals having a violaceous colour. Nearly 100 species of this beautiful genus of plants have been described, and a fine collection of them exists in the Royal Gardens at Kew. They are of easy culture, and require the same general treatment as the order to which they belong. [CACTACEÆ.]

CE'RIA, a genus of Dipterous Insects belonging to the family *Syrphidæ*. It has the following characters:—Head longer than the thorax; antennæ longer than the head, inserted on a petiole, the second and third joints forming an oval mass; stylet terminal and short; abdomen cylindrical; submarginal nervure of the wings much bent, and throwing out a rudiment of another nervure.

Five species of this genus are known; the colouring is black and yellow, which, together with an elongated and somewhat ovate form of body, gives them a resemblance to wasps. Only one has been discovered in England, and that is extremely rare—it is the *Ceria conopsoides*, and is about half an inch long; black, front of the head yellow in the male, black and yellow in the female; petiole of the antennæ elongated and yellow beneath; sides of the thorax with yellow spots; scutellum yellow, with the apex black; the second, third, and fourth segments of the abdomen, with their margin, of the same calour; legs yellow; exterior margin of the wings brown. It is also found in France. It appears not to have been found abundant anywhere.

CERITHIUM. [ENTOMOSTOMATA.]

CERIUM, a metal not found pure in nature. It occurs in several minerals, of which the following are the most remarkable —

1. *Cerite*, found near Riddarhittan, in Sweden. It occurs amorphous. Its colour is pale dull red, sometimes grayish, and its streak is white; its lustre is resinous, slightly translucent, and sufficiently hard to give sparks with steel, or 5·5. Specific gravity, 4·912.

According to Hitsinger it consists of—

Silica	18
Peroxide of Cerium	68·59
Peroxide of Iron	2
Lime	1·25
Water and Carbonic Acid	9·6—99·44

In the opinion of Dr. Thomson it is a hydrous silicated peroxide of Cerium.

2. *Cerine*, found as above, occurs massive and in imperfect crystals. Colour brownish-black, streak brownish-gray, opaque, with an imperfect metallic lustre. Hardness 5·5 to 6·0. Specific gravity, 4·173 Composition according to Berzelius:—

Silica	30·07
Oxide of Cerium	28·19
Oxide of Iron	20·7
Oxide of Copper	0·87
Alumina	11·07
Lime	9·12
Volatile Matter	0·4
	100·42

3. *Allanite*, found at Alluk, East Greenland. It occurs massive, and crystallised in the form of a doubly oblique prism. Fracture imperfect conchoidal. It is opaque, with an imperfect metallic lustre. Colour brownish-black, streak greenish-gray. Hardness, 6·0. Specific gravity, 4. It is composed, according to Stromeyer, of—

Silica	33·021
Protoxide of Cerium	21·6
Protoxide of Iron	15·101
Protoxide of Manganese	0·404
Alumina	15·226
Lime	11·08
Water	3.
	99·432

4. *Monazite*, found near Slatoust, Russia; also in the United States, where it occurs in small brown crystals, disseminated through mica-slate; at Norwich, Connecticut; at Chester, Connecticut; and York Town, New York. It is brittle, has a hardness of 5, and specific gravity of 4·8 to 5·1. It is composed of—

Oxide of Cerium	26·00
Oxide of Lantanium	23·04
Thorin	17·95
Phosphoric Acid	28·05
Oxide of Tin	2·01
Protoxide of Manganese	1·09
Lime	1·07
	99·21

5. *Cryptolite* is a phosphate of the Oxide of Cerium in minute prisms. It is found with the apatite of Arendal, Norway. It has a pale wine-yellow colour. It has a specific gravity of 4·6.

Orthite is another mineral with Cerium [ORTHITE]; so also are *Yttrocerite* [YTTROCERITE] and *Pyrochlore* [PYROCHLORE].

CERNUA, a genus of Fishes belonging to the section *Acanthopterygii* and the family *Percidæ*. It includes the Ruffe or Pope, a British fish, which has also been named *Acerina vulgaris* and *Perca Cernua*. The generic character of *Acerina*, as given by Yarrell in his 'British Fishes,' is as follows:—"Dorsal fin single, elongated, the rays of the first portion spinous, the others flexible; branchiostegous rays seven; teeth very small, uniform, numerous; head without scales; suborbital bone and pre-operculum indented; operculum ending in a single point.

In *Acerina vulgaris*, the Ruffe or Pope, the prevailing colour of the upper part of the body and head is a light olive-brown, passing into a yellowish-brown on the sides, and becoming almost silvery-white on the belly. The lateral line prominent and strongly marked. Small brown spots are disseminated over the back, dorsal fin, and tail, assuming on the latter, from their arrangement, the appearance of bars; pectoral, ventral, and anal fins, pale-brown. This fish is an inhabitant of fresh waters, and closely allied to the perch. It was first described by Dr. Caius, who called it *Aspredo*, being a translation of our word Ruffe (rough), which is applied to this fish on account of the harsh feel of its denticulated scales. It is common in all the rivers of England, especially the Thames, the Isis, and Cam, and is found in the colder parts of the European continent. It is like the perch in its habits. (Yarrell, *British Fishes*.)

CERO'COMA, a genus of Coleopterous Insects, belonging to the family *Cantharidæ* (Latreille). It has the following characters:—Antennæ short, 9-jointed, the basal joint as long as the two following; the second and next joints in succession are short and gradually increase in width to the apex of the antennæ; the terminal joint forms a distinct ovate knob; palpi moderate, all the joints of nearly equal width—such are the characters of the females. The males have the antennæ short, thick, and the joints extremely irregular in shape and size; those towards the base are uncommonly large, the terminal joint forms a large flattened knob, the joints immediately adjoining are the smallest; the palpi are also very much developed, the basal joints being very large. The head and thorax are rounded at the sides, and of about equal width; the elytra are narrow, somewhat linear, elongate, and soft.

The species of this genus are remarkable for the extraordinary antennæ of the males. They are European, and make their appearance during the summer months, frequently in great numbers in the same spot. They are found on flowers, particularly those of the wild chamomile, &c.

C. Schæfferi is about half an inch in length, and of a bright golden green above, or bluish; the legs and antennæ are yellow. In the female the base of the thighs and the tarsi are black. The colour of this species and the texture of its wings closely resemble that of the common Blister Beetle. The general form of the body is not very dissimilar: it is of a smaller size. This species is common in France.

CEROPILES. [POMPILUS.]

CERO'XYLON, a genus of plants belonging to the natural order of Palms. *C. Andicola*, the Wax-Palm of South America, is one of the most remarkable plants in the large natural order to which it belongs. It is a species with pinnated leaves and panicled polygamous flowers. Its calyx consists of three small scales; the petals are also three, but much larger and sharp-pointed. The stamens are numerous, with very short filaments. The fruit is a little round drupe, with a single seed of the same figure.

Wax-Palm (*Ceroxylon Andicola*).

This plant has received from the American Spaniards the name of Palma de Cera, or Wax-Palm, on account of the abundance of that substance yielded by the stem. It grows, according to Bonpland, in that part of the Andes which separates the valley of the Magdalena from that of the river Cauca, in 4° 35′ N. lat. Below the snow-capped mountains called Tolima, San Juan, and Quindiu, especially the last, the *Ceroxylon* grows in all its grandeur, elevating its majestic trunk, coated with a thick incrustation of wax, to the height of 180 feet among the most rugged precipices of the wild region which it inhabits. Unlike the greater part of the palm-tribe, this species avoids the heat of tropical plains, and seems incapable of existing except in regions where the temperature is lowered by elevation in the air and the contiguity of perpetual snow. It is said to make its first appearance on the sides of the Quindiu, at a height equal to that of the Puy de Dome or the passage of Mont Cenis; this is higher than the region of Cinchonas, and so cool that Humboldt does not estimate the mean temperature of the year higher at the utmost than 65° or 68° Fahr., which is at least 17 degrees lower than the mean temperature of palm countries. It does not extend over more than 15 or 20 leagues of country altogether. Its roots are fibrous and very numerous, the main root being thicker than the stem itself. The trunk is distinctly marked by rings caused by the fall of the leaves, which are from 18 to 20 feet long. The spaces between the rings are pale yellow, and smooth like the stems of a reed, and covered with a thick coating of wax and resin. This substance, melted with a third of fat, makes excellent candles. Vauquelin ascertained that this vegetable matter consists of two-thirds resin and one-third wax, which is only a little more brittle than bees-wax. The only parallel among palms to this property of exuding wax occurs in a Brazilian palm with palmated leaves, called Carnauba.

CERTHIA. [CERTHIADÆ.]

CERTHIADÆ, the Creeper Family, a family of birds placed by Mr. Vigors under his order *Scansores*, or Climbing Birds. "The genus *Certhia*," writes that author ('Linn. Trans.,' vol. xiv. p. 461), "as originally instituted by Linnæus, contained, besides the true *Certhia* and its congeners, which form the extreme family of the preceding tribe (*Picidæ*), all those birds whose slender and gradually curved bills and delicate formation of body, added to their practice of employing their tongues in taking their food, indicated a strong affinity to each other, and which have since been particularised by authors under the various names of *Nectarinia*, *Cinnyris*, *Drepanis*, &c. To the group thus known and described by the Swedish naturalist, later ornithologists, who have strictly followed his steps, have added another, discovered since his time in Australasia, similar in habits and manners, and now distinguished by the generic title of *Meliphaga*. The whole of the birds, however, thus united by close affinities, and as such generally brought together by systematic writers into one conterminous series, are decidedly divisible into two distinct groups, naturally arranging themselves under different subdivisions of the order. The family of *Certhiadæ* live upon animal food; while the remaining genera of the Linnæan *Certhia* subsist chiefly upon vegetable juices. The tongues of each, though similar in being more or less extensible, and in being the medium through which they are supplied with food, are equally distinct as the nature of the food itself. Those of the former are sharp and of a spear-like form, as if to transfix the insects which are their prey; while those of the latter are divided into tubular filaments, which appear exclusively adapted to the purposes of suction. In other particulars they exhibit an equal difference. The *Certhiadæ* climb, and their feet are of a conformable structure; but the feet of the suctorial birds are not only in general unsuited to that purpose, but they become gradually weaker, and of less use as they come nearer the type of the tribe, where they are so short and slightly formed as to be serviceable only in perching, when the bird is at rest. . . . . The two groups of the Linnæan *Certhia* are disposed in the separate departments to which the distinct nature of their food and habits more immediately unites them; while at the same time, by their forming the extremes of their respective tribes, and touching each other at the corresponding points of the circles in which they are arranged, their obvious affinities are preserved inviolate.

"In addition," continues Mr. Vigors, "to *Dendrocolaptes*, and the true *Certhia* of the present day, the family before us consists of a variety of genera which are strongly united by their corresponding habits. Among these, *Climacteris*, Temm., and *Orthonyx*, Temm., preserve the strong shafts of the tail-feathers, which are carried on to them from the true *Pici*. This construction gradually disappears in the remaining groups of the family; but the strong hind toe, and the tongue more or less extensile, and serving to spear their prey, is still conspicuous. Among such groups we may particularise the *Tichodroma*, Ill., and *Upupa*, Linn., together with the Linnæan *Sitta*, and the conterminous form of *Xenops*, Ill. Here also may be associated the *Opetiorhynchus* and *Anabates* of M. Temminck, as also the *Oxyrhynchus* of the same author. The genus may be observed to be connected with those groups of the present family which are united with the genus *Yunx* of the preceding; it is a perfect Wryneck, as justly asserted by M. Temminck, with a Creeper's foot."

Mr. Swainson ('Fauna Boreali-Americana,' vol. ii.) places the genus *Troglodytes* (Wrens) among the *Certhiadæ*, which family he also places under the *Scansores*.

Cuvier, the Prince of Canino, and Lesson, arrange the *Certhiadæ* under the *Tenuirostres*.

The character of the Family is as follows:—Bill sometimes very much curved, sometimes but little, sometimes nearly straight, rounded, slightly compressed, pointed; tongue simple, cartilaginous at the extremity; tail-feathers generally worn at the end. (Lesson.) The following are the genera enumerated by Lesson:—

Certhia. Bill moderately long, more or less curved, triangular, compressed, slender, pointed; nostrils basal, partially closed by a membrane; wings short, fourth quill longest; tail-feathers stiff, a little curved, pointed at the end.

C. familiaris (Linn.). The Creeper, Common Creeper, Tree-Creeper and Tree-Climber, *C. familiaris* (Linn.), is, according to Belon and others, the Κέρθιος of Aristotle (book ix. 17). It is Le Grimpereau of the French; Picchio Piccolo, Picchietto, Rampichino, and Piccio Rampichino, of the Italians; Baumlaufer, Kleinere Grau-Specht, or Kleinste Baum-Häcker of the Germans; Krypare of the 'Fauna Suecica;' and the Grepianog of the ancient British.

It has the bill about half an inch long, slender, and curved; head and neck above streaked with black and yellowish-brown; a white line above each eye; irides hazel; back, rump, and scapulars approaching to tawny; quills dusky, tipped and edged with white or light brown; coverts dusky-brown and yellowish-white, producing a variegated appearance; a yellowish-white bar across the wing;

breast and belly silvery-white; tail-feathers twelve, tawny-brown; length rather more than 5 inches; weight about 2 drachms (Montagu), Pennant says 5 drachms.

Creeper (*Certhia familiaris*).

The Creeper is a most restless and active little bird, ever on the alert, and climbing up and about the trunks and branches of trees intent on picking up its insect food. Though comparatively common, and a constant resident in Britain, it is not easily seen, for its activity in shifting its position makes it very difficult to follow it with the eye. At one instant it is before the spectator and the next is hidden from his view by the intervening trunk or branch, to the opposite side of which it has passed in a moment. The form of the tail and organisation of the feet are beautiful adaptations for this sort of rapid locomotion. Its note is monotonous, and often repeated.

It builds its nest in the hole or behind the bark of decayed trees, formed of dry grass and the inner part of the bark, lined with small feathers, in which six or eight eggs are deposited. While the female sits on these she is regularly fed by the male bird.

It is found in Great Britain and the continent of Europe. Pennant says that it migrates to Italy in September and October. Latham states that it is found in various parts of Germany and elsewhere on the Continent, and is also said to inhabit North America. This is confirmed by the Prince of Canino, who, in his 'Specchio Comparativo,' notes it as common and permanent near Rome, and rare near Philadelphia.

Temminck is of opinion that the *C. brachydactyla* of Brehm is identical with *C. familiaris*.

Tichodroma (*Petrodroma*, Vieill.). Bill longer than the head, triangular at the base, slightly bent, rounded, entire, and depressed at the point; nostrils horizontal; tail-feathers nearly equal, with ordinary shafts; wings long; fourth, fifth, and sixth quill the longest; *T. muraria*, C. Bonap.; *T. phœnicoptera*, Temm.; *C. muraria*, Linn. This bird is the Grimpereau de Muraille, Pic de Muraille, Ternier, Eschelette, and Echelette, of the French; Picchio Muraiolo and Picchio di Muro of the Italians; Mauer Baumlaufer of the Germans; and Wall-Creeper of Latham.

The summit of the head is of a deep ash-colour; nape, back, and scapulars bright ash; throat and front of the neck deep black; lower parts blackish-ash; coverts of the wings and upper part of the exterior barbs of the quills bright red; extremity of the alar quills black—these quills have two large white spots disposed upon the interior barbs; tail black, terminated with white and ash; bill, iris, and feet black; length 6 inches 6 lines. Such is Temminck's description of the male in its nuptial or spring dress.

The female, according to the same author, has the summit of the head of the same bright ash as the back; the throat and front of the neck white, slightly tinged with ash; and the rest of the plumage like that of the male.

It is a native of the south of Europe. Tolerably abundant in Spain and Italy, always on the most elevated rocks, and very rare in the mountains of moderate height. Never found in the north, according to Temminck. The bird is common in Provence; and the Prince of Canino notes it as permanent and rather rare near Rome, where it may however be seen creeping on the outward walls of St. Peter's. It is not a British bird, at least it has never been recorded as such.

Temminck says that what the Creeper does upon trees the Wall Creeper does against the vertical faces of rocks, on which it sticks firmly (se cramponnent fortement), without however mounting and descending by creeping. Clefts and crevices of rocks and the walls of old edifices are its favourite haunts, and sometimes, but very rarely, the trunks of trees. It feeds on insects, their larvæ, and pupæ, and is particularly fond of spiders and their eggs. Belon has figured his example clinging to a pillar with a spider in its bill. The nest is made in clefts of the most inaccessible rocks, and in the crevices of ruins at a great height.

Wall-Creeper (*Tichodroma muraria*).

The bird moults twice a year. It is in the spring only that the male has the black on the throat, and this ornament disappears before the other feathers fall. The females moult also twice, but without changing colour, which makes it impossible to distinguish the sexes after pairing and breeding time. The young may be distinguished from their parents before their first moult, but in winter no difference is observable. (Temminck.)

Dendrocolaptes (*Dendrocopus*, Vieill.) Bill long or moderate, compressed laterally, rather strong, convex, straight or curved, or only curved towards the extremity, pointed; nostrils lateral, round, open; tongue short and cartilaginous; third, fourth, and fifth quills the longest; tail-feathers stiff, pointed; hind toe shortest; claws very much curved, channeled.

D. procurvus (Temm.), *D. trochilorostris* (Wied), is the size of the blackbird. Bill strongly curved, and nearly 20 lines long; tail graduated, and each feather terminated by a stiff point; general colour cinnamon, passing into dirty ruddy gray on the head and belly; there are numerous white spots on the head and neck. It is a native of Brazil.

Dendrocolaptes procurvus.

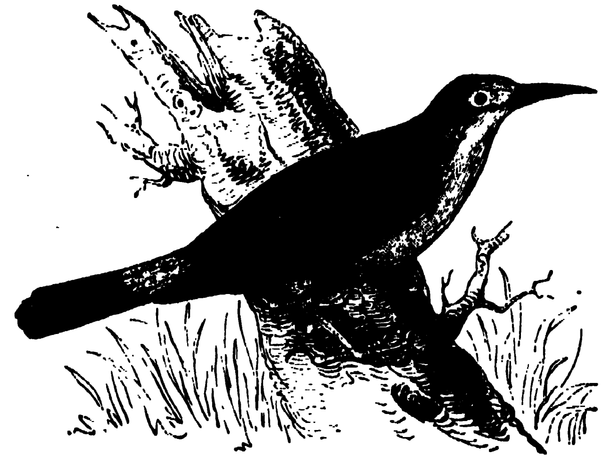
Climacteris. Bill short, weak, very much compressed throughout its length, but little curved, oval shaped; mandibles equal, pointed; nostrils basal, lateral, covered by a naked membrane; feet robust; tarsi of the length of the middle toe, which as well as the hallux are extraordinarily long; claws large and curved, channeled on the sides, subulate, very much hooked; external toe united up to the second articulation, the internal toe as far as the first; lateral toes very unequal; wings moderate; first quill short, second shorter than the third; which last and the fourth are the longest. (Temminck.)

C. Picumnus. The summit of the head is deep gray; nape and neck bright gray; wings and two middle feathers of the tail brown; a large nankeen-coloured band passes nearly through the middle of the quills; tail-feathers black, except at their origin and extremity; throat and cheeks dirty white; breast gray; feathers of the lower parts white in the middle, bordered with brown; lower coverts of the tail Isabella-colour, marked with transverse brown spots; length 6 inches 6 lines. (Temm.) Locality, Timor, Celebes, and the north coast of Australia.

This genus bears a strong relation to the Soui-mangas.

Climacteris Picumnus.

Furnarius (*Opetiorhynchos*), Temm., *Figulus*, Spix. Bill shorter than the head, as wide as it is high, compressed laterally, but little curved, entire, pointed; tongue moderate, straight, worn at the point; wings feeble. (Vieillot.) Type, *Merops rufus*, Gmel.



Furnarius rufus.

F. fuliginosus, Lesson (*C. antarctica*, Garnot).

"The genus *Furnarius*," writes M. Lesson, "was established by M. Vieillot for the reception of some small birds of Paraguay, the most celebrated among which have been placed among the Thrushes, the Creepers, the Bee-Eaters, and the *Promeropidæ*. The most anciently known, the Fournier of Buenos Ayres (*Merops rufus*. Gmel.; *Figulus albogularis*, Spix), is often noticed on account of the manner in which it constructs its nest, namely, in the form of an oven ('four'), whence comes its name. On this point we know nothing of the habits of the Fournier Brun, which lives in South America, and which approaches much in other respects to *Merops rufus*, figured by Commerson under the name of *Hornero Bonariensium* and of *Turdus furnifaber*, and which is said to be an object of veneration at La Plata. As it ought to be, the genus *Furnarius* should only contain the three species indicated by D'Azara, and that which we add under the name of *Furnarius fuliginosus*.

"This bird is five inches and a half in length; the bill is eight lines long, the tarsi an inch, and the tail two inches eight lines. The bill is slightly compressed, convex above, with the upper mandible slightly curved, entire, and exceeding the lower one; the tail is nearly rectilinear, composed of twelve feathers; the legs are feathered down to the tarsi, which are slender, elongated, with large but little apparent scutella; the middle toe is longest, the two outside ones nearly equal in length, and the external toe is united with the middle toe at its base; the claw of the posterior toe is double the length of the anterior toes, which are very much compressed at the sides, curved, and pointed. The entire plumage of the bird is a clear fuliginous brown, spread equally over all the parts of the body, the neck alone exhibiting yellow and brown ill-defined striæ; the under side of the tail is of a bright gray-brown; a yellow band of deeper tint occupies the middle of the great quills, and forms a kind of scarf when the bird is in flight; the extremity of the quills is a little deeper than the rest of the plumage, and their external border is a shade brighter." (Lesson.)

The *F. fuliginosus* inhabits the Malouine Islands. It lives upon the beach, where its familiarity and fearless disposition permits approach till it may be almost touched with the hand. Its sombre plumage has caused it to be mentioned under the name of Merle in the narratives of some voyages. Pernetty, who sojourned at the Malouines, thus describes it: "This bird is so tame that it will almost fly upon the finger; in less than half an hour I killed ten with a small switch, and almost without changing my position. It scratches in the goëmons (fucus) which the sea throws upon the beach, and there eats worms and small shrimps, which they call sea-fleas (puces de mer)." "Its flight is short. When disturbed it contents itself with flying two or three paces farther off. Its habits are solitary." (Lesson.)

Cœreba. [Nectarinidæ.]

Dicæum. Bill pointed, bent, of the length of the head, depressed and widened at the base.

The species forming this genus, instituted by Cuvier, are small, oriental, have more or less of scarlet in their plumage, and differ from the true *Certhiæ*, inasmuch as their tails are not worn, nor do they creep. It is questionable whether they do not belong to the *Nectarinidæ*; but their position will principally depend upon their habits and the form of their tongue. Cuvier places the genus next to Le Fournier (*Merops rufus*) and under *Nectarinia*.

Dicæum erythronotus.

CERTHILAUDA. [Alaudinæ.]

CERUSE, a name for White Lead. [Lead.]

CERVANTE'SIA, a name given by Ruiz and Pavon to a genus of plants, in honour of their immortal countryman Cervantes. One of the species, *C. tomentosa*, is a native of Peru, and yields seeds which are eaten in the same manner as almonds in Europe, or the Quandary Nut (*Fusanus acuminatus*), another Santalaceous plant, in Australia.

CERVICOBRANCHIATA, an order of *Mollusca*, in De Blainville's arrangement, including the genera *Patella*, *Fissurella*, &c. [Patellidæ; Fissurellidæ.]

CERVIDÆ, or CERVINA, a tribe or family of Ruminating *Mammalia*, embracing the animals popularly known as Deer. They belong to that division of the *Ruminantia*, or *Ungulata*, whose horns are deciduous, and covered when young with a deciduous hairy skin, or entirely wanting. The *Cervina*, which include the genus *Cervus* of Linnæus, are characterised by the absence of cutting teeth in the upper jaws; by the horns being deciduous, and often wanting in the females; the tarsus hairy on the hinder side; the false hoofs distinct.

Various arrangements of this tribe have been approved. The following remarks from the 'Catalogue of the Specimens of the Mammalia in the British Museum' will be the best introduction to the system followed in this article:—

"Dr. J. E. Gray, in the 'Proceedings of the Zoological Society' (1836, 67), proposed to arrange the species of Deer into three sections, according to the positions of certain tufts of hair on the hind legs, thus:—1, a tuft of hair below the middle of the outside of the metatarsus; 2, a tuft of hair above the middle of the outside of the metatarsus; and 3, with a tuft of hair on the inside of the hock. Dr. Sundevall, in his 'Pecora,' has adopted these divisions. These tufts have the advantage of being found in all ages and in both sexes; so that they can be consulted when the horns are deficient.

"M. Pucheran ('Dict. Univer. Hist. Nat.' iii. 314, 1843) divides the Deer as follows:—

"*A.* With flat horns. 1. *C. Dama* (and var. *mauricus*). *B.* With round horns. *a.* With more than two andouilleres:—1. *C. Virginianus.* 2. *C. Duvaucellii.* 3. *C. Wallichii.* 4. *C. Elaphus.* 5. *C. Wapiti.* 6. *C. macrotis.* 7. *C. macrurus.* 8. *C. occidentalis.* 9. *C. Elaphoides.* *b.* With only two andouilleres:—10. *C. Hippelaphus.* 11. *C. Aristotelis.* 12. *C. equinus.* 13. *C. marianus.* 14. *C. Peronii.* 15. *C. unicolor.* 16. *C. Axis.* 17. *C. porcinus.* 18. *C. nudipalpebra.* 19. *C. Leschenaultii.* 20. *C. Capreolus.* 21. *C. Mexicanus.* 22. *C. paludosus.* 23. *C. campestris.* *c.* Cerfs Daguets:—24. *C. nemorivagus.* 25. *C. rufus.*

"This essay is a mere compilation without any examination.

"M. Pucheran, in his 'Monographie des Espèces du Genre Cerf' ('Comptes Rendus Acad. Sci.,' 1849, ii. 775), divides the tribe *Cerviens* into four genera:—1. *Alces;* 2. *Tarandus;* 3. *Cervulus;* and 4. *Cervus.*

"Since the publication of Cuvier's Essay on Deer ('Ossemens Fossiles,' iv.), where he exhibited the development of the horns of several species; and in which he described several species from the study of the horns alone, many zoologists have almost entirely depended on the horns for the character of the species; and Mr. Hamilton Smith has been induced to separate some species on the study of a single horn. But the facilities which menageries have afforded of studying these animals, and watching the variations which the horns of the species present, have shown that several most distinct but allied species, as the Stag of Canada and India, have horns so similar that it is impossible to distinguish them by their horns. On the other hand, they have shown that animals of the same herd, or even family, and sometimes even the same specimen, under different circumstances, in succeeding years, have produced horns so unlike one another in size and form that they might have been considered, if their history was not known, as horns of very different species. These observations, and the examination of the different cargoes of foreign horn which are imported for the uses of the cutler—each cargo of which is generally collected in a single locality, and therefore would most probably belong to a single species peculiar to the district—have proved to me that the horns afford a much better character to separate the species into groups than to distinguish the allied species from one another.

"Colonel Hamilton Smith, in his monograph of the genus, separated them into genera according to the form of the horns.

"In the 'Proceedings of the Zoological Society' for 1836 I drew attention to the glands on the hind legs, as affording very good characters to arrange the genera proposed by Colonel Smith into natural groups; which in most particulars agreed with the geographical distribution of the species.

"Dr. Sundevall, in his 'Essay on Pecora,' has availed himself of the characters suggested in my paper, and has also pointed out some other external characters, such as the form and extent of the muffle, which afford good characters, and which I firmly believe are much more important for the distinction of the genera and species than those derived from the form of the skull, or the modifications of the teeth, or the form and size of the horns; as they are not like those parts so liable to alteration from age, local circumstances, and other changes during the growth of the animal; and the characters derived from these parts can be seen in the females as well as males, which is not the case with the horns, as they can only be observed in the male sex.

"These examinations have shown that the form and extent of the muffle, the position and presence of glands on the hind legs, the general form of the horns, and the kind of hair which forms the fur, taken together, afford the best characters for the arrangement of the species into natural genera, and these genera into groups. And I believe that the progress of zoology, and the natural arrangement and affinities of animals, are best promoted by the general study of all the parts of the animal taken together, rather than confining one's attention to any set of characters, and believing them as much more important than the others."

At the same time that we agree with the general principles on which Dr. Gray proposes his arrangement, we would draw especial attention to the very interesting nature and history of the development of the horns of this family of animals.

In the Museum of the Royal College of Surgeons ('Physiological Series,' No. 179) will be found a section of part of the os frontis and of the base of a Fallow-Deer's horn (*Cervus Dama*), the growth of which is nearly completed. It shows the horn to be a continuation of bone from the outer table of the skull, and the velvet-like covering of the horn to be equally continuous with the integuments of the head. It shows also the burr or pearl which has been formed round the base of the horn, and illustrates the effects of this part on the growth of the horn.

In the formation of the burr, which is the last part of the process, and takes place rapidly, the osseous tubercles of which it is composed are projected outwards, and by their pressure induce absorption of the vascular external covering; and increasing at the same time laterally, they enclose and compress the blood-vessels: thus in a short space of time the circulation is entirely obstructed, and consequently the whole of that once very vascular and sensible tegument loses its vitality, dries, shrinks, and peels off, leaving the horn a naked insensible weapon. In one of the branches (the brow antler) in this preparation, the whole of the vessels appear to have been thus obliterated; in the other a slight degree of vascularity remains, and one of the large external arterial branches is still uncompressed ('Catalogue, Physiol. Series,' vol. i.). The beautiful preparations illustrative of the process are numbered 163 to 187, both inclusive.

The rapidity with which this firm mass of bone is secreted is worthy of note. The budding horns of a male Wapiti were several inches high in ten days from their first appearance; a month afterwards there was an interval of two feet between them, measuring from branch to branch.

It is in the spring generally that the reproduction of the horn is begun. From the place whence the old horn had been separated and cast, and which at first is apt to bleed, but soon is skinned over with a fine film, the new horn sprouts. At this time there is a strong determination of blood to the head, great in proportion to the demand for such an enormous and ultimately solid secretion. The vessels from the roots swell, the vascular horn pushes up, protected by a delicate and soft covering. In this its early stage it is nearly cylindrical, and the quantity of animal heat which it contains may be in some degree imagined by gently grasping it with the hand. Gradually the antlers appear; the whole 'head,' to use the sporting term, is developed, and becomes of the firmest solidity; the animal feels its powers, and proceeds to rub off the drying and decaying 'velvet,' which may be seen at this period hanging from the horn in ragged strips, against trees and other resisting bodies, leaving at last the magnificent ornament and weapon with only the traces on its now hard surface of the blood-vessels which had produced it. Then it is that the deer, conscious of his strength, comes forth in all his grandeur, ready to do battle with any creature, even man himself, who may dare to invade his haunts. Fierce fights ensue, and the strongest male reigns paramount. The rutting season dies away, spring returns, the antlers are shed, again to be regenerated in time for the season of love.

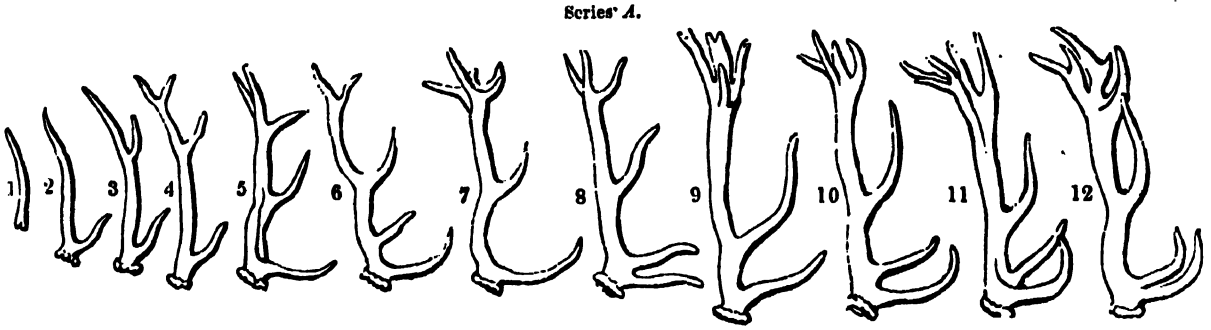
In the Common Stag or Red Deer (*Cervus Elaphus*), the shedding of the horns takes place about the end of February or during March. The Fallow-Deer sheds his horns from about the middle of April to the first weeks of May.

For the production of these annually regenerated bony masses nature has provided with her usual care. "We find it a common principle in the animal machine," says John Hunter, "that every part increases in some degree according to the action required. Thus we find muscles increase in size when much exercised; vessels become larger in proportion to the necessity of supply, as for instance in the gravid uterus. The external carotids in the stag also, when his horns are growing, are much larger than at any other time; and I have observed that in inflammation the vessels become larger, more blood passes, and there appears to be more actions taking place; but the nerves do not seem to undergo any change. The nerves of the gravid uterus are the same as when it is in a natural state; neither do the branches of the fifth and seventh pair of nerves in the stag become larger." (Hunter, 'On the Blood.')

But it must not be supposed that the antlers reach their full amplitude in the first years of the male deer's life. In the Stag or Red Deer the horns of the male do not appear till its second year, and the first which is shed (*fig.* 1, Series *A*) is straight and single, like a small thrust-sword or dagger, whence the young male is termed Daguet by the French. The next horn has generally but one antler, as in *fig.* 2; but it has sometimes two, and even three (*figs.* 3, 4, which are horns of stags in their third year). The third horn has three or four antlers, and sometimes as many as five or six, which are also the numbers of the fourth (*figs.* 5, 6). Up to this time the young male is called a Young Stag—Jeune Cerf. The fifth horn bears five or six antlers of the degree of development indicated in *figs.* 6, 7, or 8. In this stage the animal is called by the French Cerf de Dix Cors jeunement. The sixth horn, which the stag sheds at about seven years of age, is that which bestows upon the stag the appellation of Cerf de Dix Cors.

The proportional length, direction, and curvature of the antlers vary; and it often happens that there is one more or less on the one side than on the other. Independently of the number of antlers, the horns become larger, the superficial furrows more marked, the burr is more projecting, and the prominences of the frontal sinus which support the horns become shorter and wider every year. By such signs is the age of old stags, or those of from eight years upwards, determined; for after the seventh year the number of the antlers is regulated by no fixed rule. They are multiplied towards the summit of the beam, where they are conjoined into a kind of crown or palmation (*figs.* 9, 10, 11, 12). The oldest heads do not in general present more than 10 or 12 antlers (Tines, in Scotch); but some have been seen that bore the enormous number of 33. Such was the noble Cerf à 66 Cors, killed by the first king of Prussia, and presented by that monarch to Augustus I., elector of Saxony and king of Poland. This noble head is said to be still preserved at Moritzburg.

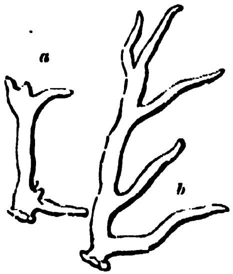
In all gradations of age after the appearance of the antlers, the second antler is more or less approximated to the first or brow antler (Maître Andouiller of the French, a name given to it because it is the largest).



Series *A*.

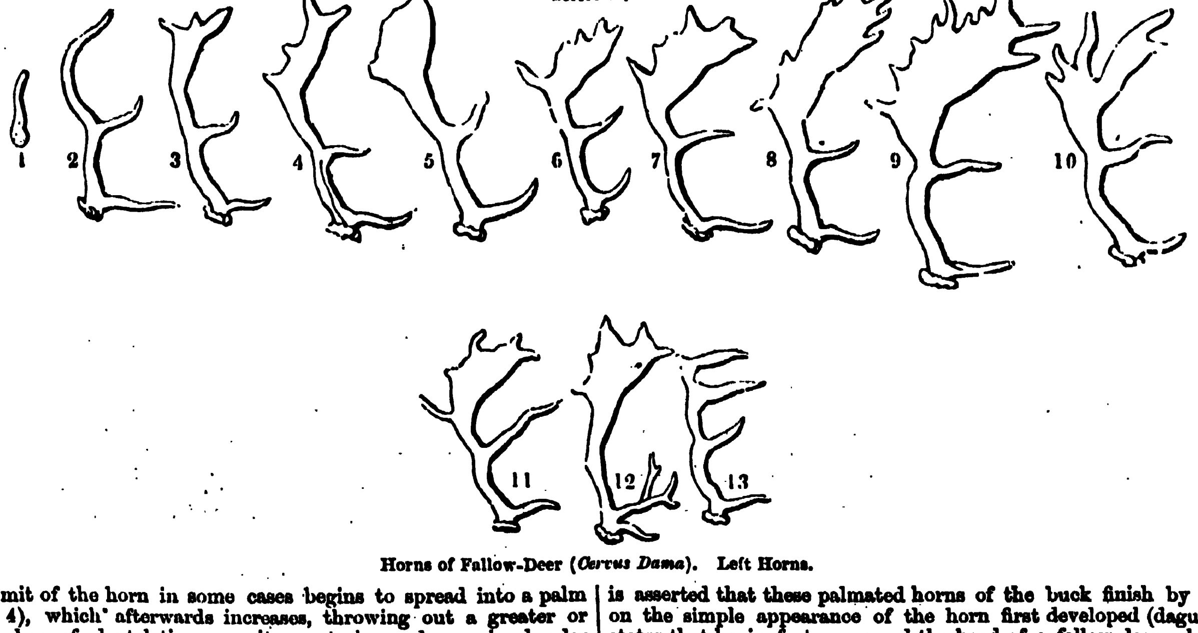
Horns of Stag (*Cervus Elaphus*). Left Horns.

The sympathy between that part of the system which regulates the development of the horns in the Deer-Tribe and the organs of generation is most remarkable. For instance, if a stag is castrated when his horns are in a state of perfection they will, it is affirmed, never be shed; if the operation is performed when the head is bare, the horns, it is said, will never be regenerated; and if it is done when secretion is actually going on, a stunted ill-formed permanent horn is the result, more or less developed, according to the period at which the animal is emasculated. Any disturbance of the system generally produces a corresponding deterioration in the horn. In the subjoined cut, *fig. a* represents the horn of a deer (*Cervus Canadensis*) produced during a voyage from America; and *b* a horn subsequently developed in the French Menagerie by the same individual, which afterwards produced a head of surprising dimensions.



a, Horn of Deer produced under unfavourable circumstances; *b*, horn of same Deer produced under more favourable circumstances.

Horns of a Fallow-Deer (*Cervus Dama*) that were not shed at the usual time in consequence of the castration of the animal. From the Museum of the College of Surgeons.



Series *B*.

Horns of Fallow-Deer (*Cervus Dama*). Left Horns.

The same system of development which we have observed in the horn with branching antlers is in great measure to be traced in the other leading form of horn, namely, the palmated horn. Taking the horn of the Fallow-Deer (*Cervus Dama*) as an example of the latter, we find the horn first put forth by the buck at two years old (when he is called a Pricket), a simple shaft, slightly curved, the concavity turned forwards (*fig.* 1, Series *B*); this curvature the horns retain throughout. The second year there are two antlers directed forwards (*fig.* 2), and the summit of the horn in some cases begins to spread into a palm (*figs.* 3, 4), which afterwards increases, throwing out a greater or less number of dentelations on its posterior and superior border (*figs.* 5, 6, 7, 8). Sometimes one or two of these dentelations form true recurrent antlers (*figs.* 6, 8). *Figs.* 8 and 9 are horns of the fourth growth, and it will be seen that they begin to be divided above. In the following years the palm is irregularly and variously divided (*figs.* 10, 11, 12, 13), so that the horns of old bucks are very frequently oddly shaped, and hardly to be recognised. With still more advanced age they continue to dwindle. Cuvier, from whom this account and the figures of the growth of the deer's horn are taken, says that it is asserted that these palmated horns of the buck finish by putting on the simple appearance of the horn first developed (dague); and states that he in fact possessed the head of a fallow-deer which had only simple horns, and whose teeth were ground down to the very roots by long use.

The reproduction of the horns is annual in the Deer of temperate and cold climates; but it has been supposed that some of the species inhabiting hot climates do not cast them every year. The palmated horn seems to be more especially given to those deer which inhabit the northern latitudes; and Colonel Smith is of opinion that it is a provision to enable the animals to remove the snow from their food.

The dental formula of the deer is, generally speaking, the same as in the giraffes, goats, antelopes, sheep, oxen, &c.; namely,

Incisors, $\frac{0}{8}$; Canines, $\frac{0—0}{0—0}$; Molars, $\frac{6—6}{6—6}=32$.

Of the molars, both in the upper and lower jaws, six are true and six false. In the upper jaw the three first molars are bordered by a thick crest on their internal surface; the three next have all the characters of the molars in the dromedaries. [CAMELUS.] In the lower jaw the first incisor is the longest, the second and the third rather decrease, and the fourth is very small; all have cutting edges. The two first false molars are simple; the third has a process or heel at its posterior part, and the three others do not differ from those of the upper jaw. In the formula given above the canines are noted as absent; but this general rule is not without exception, some of the species presenting canines similar to those of the Musks (*Moschus*) in the upper jaw. The Muntjak has these teeth largely developed.

The Deer-Tribe possess the Lachrymal Sinus, or, as it is often termed, the Suborbital Sinus (Larmiers of the French, Tear-Pits of the English, Crumen of others), even more universally than the Antelopes. [ANTILOPEÆ.]

The late Mr. Bennett was of opinion that the use of the lachrymal sinus, which has long remained a problem to zoologists, must be referred to sexual relations. In support of this opinion he has referred to the condition of this organ in some old Indian Deer formerly in the possession of the Zoological Society in the Gardens in Regent's Park.

Professor Owen at one time conceived it possible that the secretion of these glands, when rubbed upon projecting bodies, might serve to direct individuals of the same species to each other. He endeavoured to test the probability of this supposition by preparing a tabular view of the relations between the habits and habitats of the several species of Antelopes and their suborbital, maxillary, post-auditory, and inguinal glands, in order to be able to compare the presence and degrees of development of these glands with the gregarious and other habits of the Antelope-Tribe. He has stated however that it was evident from this table that there is no relation between the gregarious habits of the Antelopes which frequent the plains and the presence of the suborbital and maxillary sinuses; since these, besides being altogether wanting in some of the gregarious species, are present in many of the solitary frequenters of rocky mountainous districts. The supposition therefore that the secretion might serve, when left on shrubs or stones, to direct a straggler to the general herd, falls to the ground. ('Zool. Proc.,' 1836.)

The osteological structure of the Deer-Tribe is such as would be expected when it was necessary that the bony framework should exhibit a union of lightness and strength necessary for an animal whose life is to depend on its agility and defensive powers.

The *Cervidæ* are widely spread, and seem capable of being so modified as to withstand the extremes of heat and cold.

The following arrangement of the Deer is proposed by Dr. J. E. Gray:

A. The Deer of the Snowy Regions have a very broad muzzle, entirely covered with hair. The horns are expanded and palmate; and the fawns are not spotted.

a. The Alcine Deer have no basal anterior snag to the horns, and a small bald muffle between the nostrils, as the genus *Alcis.*

b. The Rangerine Deer have a large basal anterior snag to the horns close on the crown or burr, and no muffle, as *Tarandus.*

B. The Deer of the Temperate or Warmer Regions have a tapering muzzle ending in a bald muffle. The fawns, and sometimes the adults, are spotted.

c. The Elaphine Deer have a distinct anterior basal snag to the horns, the muffle broad, and separated from the lip by a hairy band; and the tuft of hair on the outside of the hind leg, above the middle of the metatarsus, as *Cervus* and *Dama.*

d. The Rusine Deer have a distinct anterior basal snag to the horns; the muffle very high, and not separate from the edge of the lips; and the tuft of hair on the outside of the hind leg, above the middle of the metatarsus, as *Rucervus, Panolia, Rusa, Axis, Hyelaphus,* and *Cervulus.*

e. The Capreoline Deer have no basal anterior snag to the horns, the first branch being some distance above the burr; the crumen (and pit in the skull) generally small, as *Capreolus, Cariacus, Blastocerus, Furcifer, Coassus,* and *Pudu.*

The Alcine and Rangerine Deer are confined to the northern part of both continents; the Elaphine and Rusine Deer to the Eastern World (the latter almost exclusively to the warmer part of Asia); all the Capreoline Deer are peculiar to America. The only exception to these rules are—the Wapiti Deer of the Elaphine group is found in Northern America, and the Roe-Buck and Ahu of the Capreoline group are found in Europe and Northern Asia.

The following is an arrangement of the genera and species of the tribe *Cervina* of Gray:—

Sub-Tribe 1. ALCEÆ.
Genus, *Alces.*
1. *A. Malchis,* the Elk.
Sub-Tribe 2. RANGERINÆ.
Genus, *Tarandus.*
2. *T. Rangifer,* the Caribou or Rein-Deer.
Sub-Tribe 3. ELAPHINÆ.
Genus, *Cervus.*
3. *C. Canadensis,* the Wapiti.
4. *C. Elaphus,* the Stag.
5. *C. Barbarus,* the Barbary Deer.
6. *C. Wallichii,* the Bara Singa.
7. *C. affinis,* the Saul-Forest Stag.
8. *C. Sika,* the Sika.
Genus, *Dama.*
9. *D. vulgaris,* the Fallow-Deer.
Sub-Tribe 4. RUSINÆ.
Genus, *Panolia.*
10. *P. Eldii,* the Sungnai.
Genus, *Rucervus.*
11. *R. Duvaucellii,* the Bahrainga.
Genus, *Rusa.*
12. *R. Aristotelis,* the Samboo.
13. *R. Dimorphe,* the Spotted Rusa.
14. *R. Hippelaphus,* the Mijangan Banjoe.
15. *R. equinus,* the Samboe.
16. *R. Peronii,* the Smaller Rusa.
17. *R. Philippinus,* the Philippine Rusa.
18. *R. lepida,* the Sundevall Rusa.
Genus, *Axis.*
19. *A. maculata,* the Axis.
20. *A. pseudaxis,* the Spotted Axis.
Genus, *Hyelaphus.*
21. *H. porcinus,* the Lugna Para.
Genus, *Cervulus.*
22. *C. vaginalis,* the Kijang.
23. *C. moschatus,* the Kegan.
24. *C. Reevesii,* the Chinese Muntjak.
Sub-Tribe 5. CAPREOLINÆ.
Genus, *Capreolus.*
25. *C. Caprea,* the Roe-Buck.
26. *C. Pygargus,* the Ahu.
Genus, *Blastocerus.*
27. *B. paludosus,* the Guazupuco.
28. *B. campestris,* the Mazame.
Genus, *Frucifer.*
29. *F. Antisiensis,* the Tarush.
30. *F. Huamel,* the Guemul.
Genus, *Cariacus.*
31. *C. Virginianus,* the American Deer.
32. *C. Mexicanus,* the Mexican Deer.
33. *C. leucurus,* the White-Tailed Deer.
34. *C. nemoralis,* the Cariacou Deer.
35. *C. punctulatus,* the Californian Roe.
36. *C. Lewisii,* the Black-Tailed Deer.
37. *C. macrotis,* the Mule-Deer.
Genus, *Coassus.*
38. *C. nemorivagus,* the Gauzu-viva.
39. *C. rufus,* the Cuguacu-ete.
40. *C. superciliaris,* the Eye-Browed Brocket.
41. *C. auritus,* the Large-Eared Brocket.
Genus, *Pudu.*
42. *P. humilis,* the Venada.

In selecting a few of these animals for description we shall follow the above arrangement:—

1. *Alces Malchis,* the Elk or Moose. This animal is the *Alces Antiquorum* of Rüppell; *Cervus Alces* of Linnæus; Moose Deer, Moose or Elk, American Black Elk, Flat-Horned Elk, of English writers; the Eland and Orignal of Buffon and others; Elch of the Germans; Loss of the Russians; *Alces* of Cæsar; *Alce* of Pliny.

"This animal is the largest of the genus, being higher at the shoulders than the horse; its horns weigh sometimes near 50 lbs. Accordingly, to bear this heavy weight its neck is short and strong, taking away much of the elegance of proportion so generally predominant in the deer. But when it is asserted that the elk wants beauty or majesty, the opinion can be entertained by those who have seen the female only, the young, or the mere stuffed specimens; for us, who have had the opportunity of viewing the animal in all the glory of its full-grown horns, amid the scenery of his own wilderness, no animal could appear more majestic or more imposing. It is however the aggregate of his appearance which produces this effect; for when the proportions of its structure are considered in detail they certainly will seem destitute of the harmony of parts which in the imagination produces the feeling of beauty. The head measuring above two feet in length is narrow and clumsily shaped by the swelling upon the upper part of the nose and nostrils; the eye is proportionably small, and sunk; the ears long, hairy, and asinine; the neck and withers are surmounted by a heavy mane; and the throat furnished with long coarse hair, and in younger specimens encumbered with a pendulous gland: these give altogether an uncouth character to this part of the animal. Its body however is round, compact, and short; the tail not more than four inches long; and the legs, though very long, are remarkably clean and firm; this length of limbs and the overhanging lips have caused the ancients to fancy that it grazed walking backwards. The hair of the animal is coarse and angular, breaking if bent. Its movements are rather heavy, and the shoulders being higher than the croup, it does not gallop, but shuffles or ambles along, its joints cracking at every step, with a sound heard to some distance. Increasing its speed, the hind feet straddle to avoid treading on its fore heels, tossing the head and shoulders like a horse about to break from a trot to a gallop. It does not leap, but steps without effort over a fallen tree, a gate, or a split fence. During its progress it holds the nose up, so as to lay the horns horizontally back. This attitude prevents its seeing the ground distinctly; and as the weight is carried very high upon the elevated legs it is said sometimes to trip by treading on its fore heels, or otherwise, and occasionally to give itself a heavy fall. It is probably owing to this occurrence that the elk was believed by the ancients to have frequent attacks of epilepsy, and to be obliged to smell its hoof before it could recover; hence the Teutonic name of Elend (miserable), and the reputation especially of the fore hoofs as a specific against the disease." (Smith.) The Elk is an inhabitant of woods in the northern parts of both continents.

In 'A perfect Description of Virginia' (small 4to. 1649), we find it thus written: "The elkes are as great as oxen, their horns six foot wide, and have two calves at a time." Hearne remarks that the horns of the Moose occasionally exceed 60 lbs., and that their texture is harder than that of any other deer-horns to be found in the Fur Countries. Lawson ('Nat. Hist. of Carolina') says, "The elk is a monster of the venison sort. His skin is used almost in the same nature as the buffelo's (bison's). Some take him for the red deer of America, but he is not; for if brought and kept in company with one of that sort, he will never couple. . . . . His horns exceed (in weight) all creatures which the New World affords." Richardson states that he has been informed that the males sometimes attain a weight of eleven or twelve hundred pounds.

"The flesh of the moose is very good, though the grain is but coarse, and it is much tougher than any other kind of venison. The nose is most excellent, as is also the tongue, though by no means so fat and delicate as that of the common deer (rein-deer). The fat of the intestines is hard like suet; but all the external fat is soft like that of a breast of mutton, and when put into a bladder is as fine as marrow. In this they differ from all the other species of deer, of which the external fat is as hard as that of the kidnies." (Hearne.) In the 'Perfect Description of Virginia,' above quoted, it is stated that the "skins make good buffe, and the flesh as good as beefe." Lawson, though he speaks of the good qualities of the skin, does not seem to have so high an opinion of the flesh. "His flesh," says Lawson, "is not so sweet as the lesser deers." Richardson remarks that the flesh of the moose is more relished by the Indians and residents in the Fur Countries than that of any other animal, and principally, he believes, on account of the soft fat. In his opinion, corroborating the old book above quoted, the flesh bears a greater resemblance in its flavour to beef than to venison.

The same author describes the dung of the animal as being in the form of brown oval pellets, and such were the droppings from the individuals kept at the Gardens of the Zoological Society in the Regent's Park. "The skins," Sir John Richardson observes, "when properly dressed, make a soft, thick, pliable leather, excellently adapted for mocasins, or other articles of winter clothing. The Dog-Ribs," he adds, "excel in the art of dressing the skins, which is done in the following manner:—They are first scraped to an equal thickness throughout, and the hair taken off by a scraper, made of the shin-bone of a deer, split longitudinally; they are then repeatedly moistened and rubbed, after being smeared with the brains of the animal, until they acquire a soft spongy feel; and lastly, they are suspended over a fire made of rotten wood until they are well impregnated with the smoke. The last-mentioned process imparts a peculiar odour to the leather, and has the effect of preventing it from becoming so hard after being wet as it would otherwise do." ('Fauna Boreali-Americana.')

"Du Pratz," writes Sir John Richardson, "informs us that in his time moose-deer were found as far south as the Ohio, and Denys says that they were once plentiful on the island of Cape Breton, though at the time he wrote they had been extirpated. At present, according to Dr. Godman, they are not known in the State of Maine, but they exist in considerable numbers in the neighbourhood of the Bay of Fundy. They frequent the woody tracts in the Fur Countries to their most northern limit. Several were seen on Captain Franklin's expedition at the mouth of the Mackenzie River, feeding on the willows, which owing to the rich alluvial deposits on that great river extend to the shores of the Arctic Sea in lat. 69°. Farther to the eastward, towards the Coppermine River, they are not found in a higher latitude than 65°, on account of the scarcity on the Barren Grounds of the aspen and willow, which constitute their food. I have not been able to ascertain whether they occupy the whole width of the continent or not. Mackenzie saw them high up on the eastern declivity of the Rocky Mountains near the sources of the Elk River, but I suspect that they are rarely, if ever, found to the westward of the Mountains. Authors mention that the moose generally form small herds in Canada.

The Elk or Moose (*Alces Malchis*).

"In the more northern parts the moose-deer is quite a solitary animal, more than one being very seldom seen at a time, unless during the rutting season, or when the female is accompanied by her fawns. It has the sense of hearing in very great perfection and is the most shy and wary of all the deer-species, and on this account the art of moose-hunting is looked upon as the greatest of an Indian's acquirements, particularly by the Crees, who take to themselves the credit of being able to instruct the hunters of every other tribe. The skill of a moose-hunter is most tried in the early part of the winter; for during the summer the moose, as well as other animals, are so much tormented by musquitoes that they become regardless of the approach of man. In the winter the hunter tracks the moose by its footmarks in the snow, and it is necessary that he should keep constantly to leeward of the chase and make his advances with the utmost caution, for the rustling of a withered leaf or the cracking of a rotten twig is sufficient to alarm the watchful beast. The difficulty of approach is increased by a habit which the moose-deer has of making daily a sharp turn in its route, and choosing a place of repose so near some part of its path that it can hear the least noise made by one that attempts to track it. To avoid this the judicious hunter, instead of walking in the animal's footsteps, forms his judgment from the appearance of the country of the direction it is likely to have taken, and makes a circuit to leeward until he again finds the track. This manœuvre is repeated until he discovers, by the softness of the snow in the foot-marks and other signs, that he is very near the chase. He then disencumbers himself of everything that might embarrass his motions, and makes his approach in the most cautious manner. If he gets close to the animal's lair without being seen, it is usual for him to break a small twig, which alarming the moose, it instantly starts up, but not fully aware of the danger squats on its hams and voids its urine preparatory to setting off. In this posture it presents the fairest mark, and the hunter's shot seldom fails to take effect in a mortal part. In the rutting season the bucks lay aside their timidity, and attack every animal that comes in their way, and even conquer their fear of man himself. The hunters then bring them within gun-shot by scraping on the blade-bone of a deer and by whistling, which, deceiving the male, he blindly hastens to the spot to assail his supposed rival. If the hunter fails in giving it a mortal wound as it approaches, he shelters himself from its fury behind a tree, and I have heard of several instances in which the enraged animal has completely stripped the bark from the trunk of a large tree by striking with its fore feet."

With respect to the food of the Moose the same traveller says, "Their legs are so long, and their necks so short, that they cannot graze on the level ground like other animals, but are obliged to browse on the tops of large plants and the leaves of trees in the summer, and in winter they always feed on the tops of willows and the small branches of the birch-tree, on which account they are never found during that season but in such places as can afford them a plentiful supply of their favourite food; and although they have no fore teeth in the upper jaw, yet I have often seen willows and small birch-trees cropped by them in the same manner as if they had been cut by a gardener's shears, though some of them were not smaller than a common pipe-stem. They seem particularly partial to red willows" (*Cornus alba*). To the eastward of the Rocky Mountains the evergreen leaves of the *Gualtheria Shallon* form, according to Lewis and Clark, a favourite part of the food of the moose-deer.

Mr. Lloyd ('Field Sports of the North of Europe,' vol. ii.) observes that the Elk was at one time numerous in most parts of Sweden and Norway; but owing to the increased population and other causes it is now only to be met with in particular districts. In Scania, he adds, the most southern province of Sweden, where elks once abounded, none are now to be found.

M. Nilsson states that the Elk cannot endure so cold a climate as the stag, 64° of latitude being the extreme limit at which it is met with in the Scandinavian peninsula.

Mr. Lloyd states that the period of gestation is about nine months, and that the female brings forth about the middle of May from one to three young ones; but it is seldom that she has more than two. At this period the mother retires alone to the wildest recesses of the forest. After a lapse of two or three days, the fawns, which are of a light brown colour, have sufficient strength to follow their dam everywhere; they keep with her until they are in their third year, when she leaves them to shift for themselves.

Mr. Lloyd thus describes the habits and uses of the European Elk:—"The elk is a long-lived animal; he does not attain to his full growth until after his fourteenth year. At least so it is to be presumed, as up to that period his horns, which are of a flat form, are annually provided with an additional branch. He sheds his horns about the month of February in each year. The female elk, unlike the rein-deer of that sex, has no horns. The horns of the young male elk are perceptible nine months after its birth: for the first year they are cylindrical and short; the second year they are about a foot in length, but not branched; the third year two points are discernible; the fourth year three; the fifth year they are full grown in length. From that time forward they yearly increase in breadth and in the number of branches until there are as many as fourteen on each horn.

"By nature the elk is timorous, and he usually flies at the sight of man. In the rutting season, however, like other animals of the deer kind, he is at times rather dangerous. His weapons are his horns and hoofs; he strikes so forcibly with the latter as to annihilate a wolf or other large animal at a single blow. It is said that when the elk is incensed, the hair on his neck bristles up like the mane of a lion, which gives him a wild and frightful appearance.

"The usual pace of the elk is a high shambling trot, and his strides are immense, but I have known him when frightened to go at a tremendous gallop. In passing through thick woods he carries his horns horizontally, to prevent them from being entangled in the branches. From the formation of his hoofs he makes a great clattering, like the rein-deer when in rapid motion. In the summer season the elk usually resorts to morasses and low situations; for, like other animals of the deer kind, he frequently takes to the water in warm weather; he is an admirable swimmer. In the winter time he retires to the more sheltered parts of the forest, where willow, ash, &c. are to be found; as from the small boughs of these trees he obtains his sustenance during that period of the year. In the summer and autumn the elk is often to be met with in small herds, but in the winter there are seldom more than two or three in company. At the latter season indeed he is frequently alone.

"The flesh of the elk, whether fresh or smoked, is very excellent; the young are particularly delicious. According to Mr. Nilsson, it resembles in taste that of the stag. The tongue and the nose are thought to be great delicacies in Scandinavia as well as in America. Great virtue was once placed in the hoof of that animal, as parings of it were supposed to be a specific against the falling sickness and other disorders; but this idle notion must by this time, I should think, be nearly exploded. The skin is convertible to many purposes, and is very valuable. Mr. Greiff says:—'It is not long since that a regiment was clothed with waistcoats made from the hides of those animals, which were so thick that a ball could scarcely penetrate them.' He adds further, that 'when made into breeches, a pair of them among the peasantry of former days went as a legacy for several generations.'

"The elk is easily domesticated: several instances have come to my knowledge. I had a fawn in my own possession a year ago, but from want of proper nurture it died. Formerly these animals were made use of in Sweden to draw sledges, but owing, as it was said, to their speed frequently accelerating the escape of people who had been guilty of murders, or other crimes, the use of them was prohibited under great penalties. Though I apprehend those ordinances if not abrogated are obsolete, I am not aware that the elk is ever made use of in that kingdom at the present day, either to draw a sledge or for other domestic purposes.

"In Sweden, as I have observed, it is contrary to law at this particular time to kill the elk at any season of the year: this is not the case in Norway; for in that country as I have just shown, these animals may be destroyed with certain limitations as to numbers, from the 1st of July to the 1st of November inclusive. The penalty however for killing an elk out of season in Norway is very much heavier than in Sweden; it amounts indeed, including legal expenses, &c., to about 20*l.*, which is no inconsiderable sum in that kingdom." (Lloyd, 'Northern Field Sports,' vol. ii. p. 329 et seq.)

2. *Tarandus Rangifer* (Bonaparte), the Rein-Deer. This animal has a multitude of synonyms. It is the *Cervus Tarandus*, Linnæus; *Cervus Rangifer*, Ray; *Cervus Grœnlandicus*, Brisson; *Cervus coronatus*, Geoffroy; *Rangifer Tarandus*, Gray; *Cervus palmatus*, Johnston; *Tarandus*, Pliny; *Rangifer*, Gesner; the Rein-Deer, Caribou, and Greenland Buck of English writers; Renthier, Renhirsch of the Germans; Renne of Buffon; Carrebœuf of the French Canadians; and Oleen of the Russians. Several varieties have been recognised; amongst others, a small variety which goes by the following names:—

1. Woodland Caribou.
2. Great Caribou of the Rocky Mountains.
3. Labrador or Polar Caribou.
4. Siberian Rein-Deer.
5. Newfoundland Caribou.

On this animal Dr. J. E. Gray observes that it "varies exceedingly in size. In the British Museum there are specimens varying from 41 to 50 inches high at the withers."

Richardson observes, "There are two well-marked and permanent varieties of Caribou that inhabit the Fur Countries: one of them (Woodland Caribou) confined to the woody and more southern district; and the other (Barren-Ground Caribou) retiring to the woods only in the winter, but passing the summer on the coast of the Arctic Seas, or on the Barren Grounds so often mentioned in this work." ('Faun. Bor.-Amer.,' p. 299.)

The large Siberian variety is ridden on by the Tungusians. They also use them for draught, as the Laplanders do the smaller variety.

They have a large variety in Newfoundland, nearly as large as a heifer. They have very large and heavy horns. There are some horns of this variety in the British Museum. Dr. Mildendorf informed Dr. J. E. Gray that the horns of the large Siberian variety were as large as and greatly resembled the horns from Newfoundland in the Museum collection.

Pallas observes, "Americæ forte continuo, gregatim verno tempore per glacies admigrant, paulo diversi à Siberiâ urguibinis et verosimillime Americani." ('Zool. Ross. Asiat.' i. 208.)

In winter the hair of the Rein-Deer is long, thick, gray-brown; neck, rump, belly, ring round the hoof, and end of nose, white. In summer the same animal has short dark sooty-brown hair, with the parts which are white in winter being rather paler gray-brown.

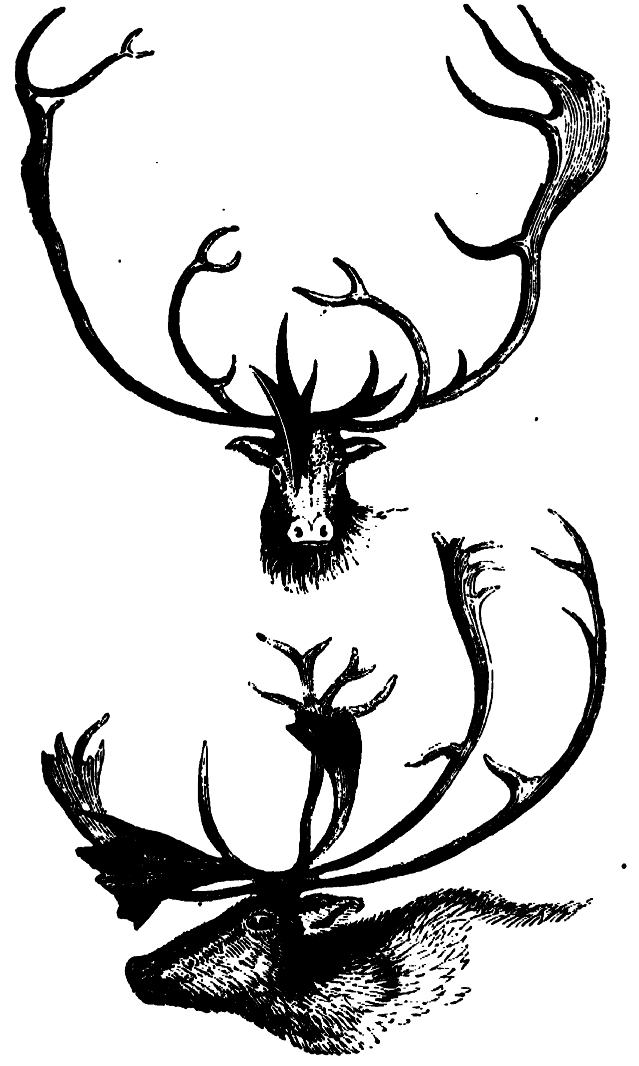
The tame Rhendeer, or Rein-Deer, of the Laplanders, is, according to Hoffberg ('Amœn. Acad.,' vol. iv.), at the end of his back an ell and a half high, and his length, from horns to tail, is two ells, whilst from the navel to the back-bone he measures three-quarters of an ell. On casting his coat his hair is at first brownish-yellow, but as the dog-days approach it becomes whiter, till it is at last almost entirely white. Round the eye the colour is always black. The longest hair is under the neck; the mouth, tail, and parts near the latter are white, and the feet, at the insertion of the hoof, are surrounded with a white ring. The hair of the body is so thick that the skin cannot be seen when it is put aside, for it stands erect, as in other animals of the same genus, but is much thicker. When the hair is cast it does not come away with the root, but breaks at the base.

The horns are cylindrical, with a short branch behind, compressed at the top and palmated with many segments, beginning to curve back in the middle, and an ell and a quarter long. A single branch sometimes, but seldom two, springs from each horn in front, very near the base, frequently equalling the length of the head, compressed at the top and branched. The distance between the tips equals the length.

The horns of the female are like those of the male, but less, more slender, and not so much branched. She has four true paps and two false ones.

The horns grow in the usual manner, and during the early part of their growth are extremely sensible, and suffer from the clouds of gnats (*Culex pipiens*) that form one of the persecutions of both deer and owner. About autumn, before rutting time, they have become hard, and the velv[illegible] rubbed off. Towards the end of November the male loses his horns, but the female retains hers till she brings forth; if barren, she drops them in the beginning of November. The wild animal grows to a much larger size than those which are tamed.

Geographical Distribution.—Northern Europe, Asia, and America. Captain James Clark Ross, in the Appendix to Sir John Ross's 'Last Voyage,' says that although this animal was seen in great numbers on the isthmus of Boothia, only one individual was killed in the course of their late voyage. It was a fine buck, of larger size than ordinary, and weighed 250 lbs.; the average of those killed at Spitzbergen and Melville Island did not exceed half that weight. The does arrive about the middle of April, the bucks nearly a month later; and herds of several hundreds were seen about the isthmus towards the end of May. Although they migrate towards the middle of September to milder climes, yet stragglers are occasionally seen in the winter. They are indeed spread, as Mr. Bennett observes, "abundantly through all the habitable parts of the arctic regions and the neighbouring countries, extending in the New Continent to a much lower latitude than in the Old, and passing still farther south on all the principal mountain chains. In America the southern limit of the



Heads of two old buck Caribou of the Barren Grounds. From Sir John Richardson's cuts taken from Captain Back's drawings.

Rein-Deer across nearly the whole continent appears to be about the parallel of Quebec; but the animal is most numerous between 63° and 66° N. lat. Passing westward it is said to be unknown in the islands interposed between America and Asia, but is again abundant in Kamtchatka, throughout nearly the whole of Siberia, in Northern Russia, Sweden, and Norway, and more especially in Finmark and Lapland. In these latter countries the numbers of the few wild herds that still exist are suffering a constant diminution, every art being put in practice by the hardy natives to reclaim and domesticate an animal which constitutes their sole property, the source of all their comforts, and the very means of their existence; without which their land would actually be, as at a first glance it seems, a bleak and uninhabitable desert. According to M. Cuvier, the Baltic forms in Europe its southern limit; in Asia however it extends along the Ural chain to the foot of the Caucasus; and [illegible] have the authority of a passage in Cæsar's 'Commentaries,' which can scarcely apply to any other animal, for its having existed in his day in the Hercynian Forest. The boundaries of this immense tract of woodland are certainly not very well defined; but this location would imply, at all events, a more southern European habitat than any that is at present known. Again, crossing the ocean, we find the Rein-Deer at Spitzbergen, in Greenland, and in Newfoundland; but it has been said by Pennant, and this has been repeated by Sir John Richardson, in his valuable zoology of the Fur Countries of North America, not to be known in Iceland. This statement, which was scarcely true at the time when Pennant wrote, is not by any means correct as refers to the present day. About eighty years since, as we learn from Van Troil's 'Letters on Iceland,' thirteen of these animals were imported from Norway, ten of which dying on the passage, only three were landed. These were turned out into the mountains, and have since multiplied to such an extent in the interior and unfrequented parts of the country that their progeny was estimated by Count Trampe, the governor, in 1809, the period of Dr. Hooker's visit, at no less than 5000 head. Herds of forty, sixty, or even a hundred individuals, are said, both by Dr. Hooker and by Sir George Mackenzie, who visited the island in the following summer, to be not uncommon in the mountains. They are however of little use to the inhabitants, who have made no attempts to domesticate them, and are too poor to purchase powder and ball for their destruction. It does not appear indeed that they are much sought after, the cow and the sheep thriving extremely well upon the island, and supplying the place of the deer in almost every respect. We may add, that according to Mr. (Sir Arthur) Brooke, an importation of six bucks and twenty-four does took place in 1777, about seven years after the period of the first introduction of the animal into Iceland." ('Gardens and Menagerie of the Zoological Society,' vol. i.)

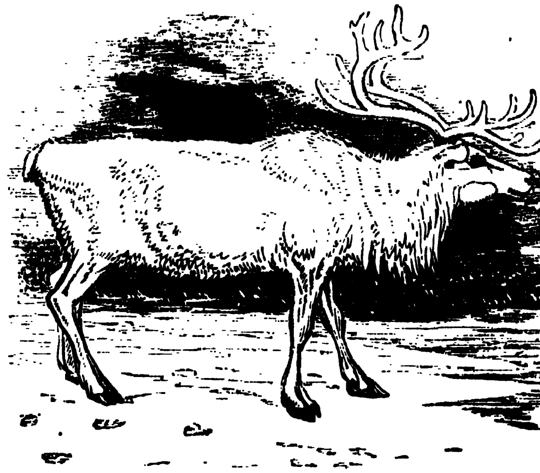
The size of the Rein-Deer, widely spread as it is, varies very much according to the accidents of climate; and if authors are to be credited their weight ranges from 60 to 400 lbs. The latter is probably an exaggeration, but it is evident that the weight increases in proportion to the proximity of the animal to the Pole. According to Sir John Richardson, the bucks of the variety called the Barren-Ground Caribou weigh, exclusive of the offal, when in good condition, from 90 to 130 lbs., whilst he describes the Woodland Caribou as much larger; and Captain (Sir John) Franklin makes the weight of the latter from 200 to 240 lbs. The buck killed on the isthmus of Boothia was, as we have seen, 250 lbs.; while the average of three killed at Spitzbergen and on Melville Island did not exceed half that weight. The Rein-Deer of Norway and Sweden are diminutive when compared with those of Finmark and Lapland, which in their turn yield to those of Spitzbergen; and these again fall short of the more Polar races. The sledge-deer of the Laplanders are small when compared with those reared by the Tungusians of the north of Asia, who ride upon them.

The food of the Rein-Deer varies with the seasons and the climate. Lapland, says Hoffberg, in the memoir above quoted, is divided into two tracks, called the alpine and woodland country. Those immense mountains called in Sweden Fjellen divide that country from Norway, extending towards the White Sea as far as Russia, and are frequently more than twelve miles in breadth. The other, called the woodland division, lies to the east of this, and differs from the neighbouring provinces of Norway by its soil, which is exceedingly stony and barren, being covered with one continued tract of wood, of old pine-trees. This tract has a very singular appearance. The trees above are covered over with great quantities of a black hanging lichen, growing in filaments resembling locks of hair, while the ground beneath appears like snow, being totally covered with white lichens. Between this wood and the Alps lies a region called the Woodland, or Desert Lapmarc, of 30 or 40 miles in breadth, of the most savage and horrid appearance, consisting of scattered uncultivated woods and continued plains of dry barren sand mixed with vast lakes and mountains. When the mosses on part of this desert tract have been burnt, either by lightning or any accidental fire, the barren soil immediately produces the white lichen which covers the lower parts of the Alps. The Rein-Deer in summer seek their highest parts, and there dwell amidst their storms and snows, not to fly the heat of the lower regions, but to avoid the gnat and gad-fly. In winter these intensely cold mountains, whose tops reach high into the atmosphere, can no longer support them, and they are obliged to return to the desert, and subsist upon the lichens. Of these its principal food is the rein-deer lichen. There are, says Hoffberg, two varieties of this; the first is called *Lichen sylvestris*, which is extremely common in the barren deserts of Lapland, and more particularly in its sandy and gravelly fields, which it whitens over like snow; its vast marshes, full of tussocks of turf, and its dry rocks are quite grown over by it. The second variety of this plant, which is less frequent than the former, is named the Alpine; this grows to a greater height, with its branches matted together: it has this name because when those mountains are cleared of their wood the whole surface of the earth is covered with it; yet it is seldom to be found on their tops. When the woods become too luxuriant the Laplander sets fire to them, as experience has taught him that when the vegetables are thus destroyed, the lichen takes root in the barren soil and multiplies with facility; though it requires an interval of eight or ten years before it comes to a proper height. The Laplander esteems himself opulent who has extensive deserts producing this plant exuberantly. When it whitens over his fields he is under no necessity of gathering in a crop of hay against the approach of winter, as the Rein-Deer eats no dried vegetable, unless perhaps the River Horsetail (*Equisetum fluviatile*). They root for this lichen under the snow like swine in a pasture; their foreheads, nose, and feet are guarded with a hard skin closely attached to those parts that they may not be hurt by the icy crust which covers the surface of the snow. The very strong shoes which the Laplander esteems so much are made of those parts of the hide. It sometimes happens (but very rarely) that the winter sets in with great rains, which the frost immediately congeals; the surface of the earth is covered with a coat of ice before the snow falls, and the lichen is entirely encrusted and buried in it: thus the Rein-Deer is sometimes starved, and a famine attacks the Laplanders. In such an exigence they have no other resource than that of felling old fir-trees grown over with the hairy liverworts. These afford but a very inadequate supply even for a small herd, but the greater part of a large one, in such a case, is sure to perish with hunger. In the summer, when the Rein-Deer ranges upon the Alps, a number of plants afford it food. Hagstrom states that it refuses to eat 46 species, the names of which he gives. Richardson states that the Barren-Ground Caribou, which resort to the coasts of the Arctic Sea in summer, retire in winter to the woods lying between 63° and 66° N. lat., where they feed on the *Usneæ*, *Alectoriæ*, and other lichens which hang from the trees and on the long grass of the swamps. About the end of April, when the partial melting of the snow has softened the *Cetrariæ*, *Cornicülariæ*, and *Cenomyces*, which clothe the Barren Grounds like a carpet, they make short excursions from the woods, but return to them when the weather is frosty. In May the females proceed towards the sea-coast, and towards the end of June the males are in full march in the same direction. At that period the sun has dried up the lichens on the Barren Grounds, and the Caribou frequent the moist pastures which cover the bottoms of the narrow valleys on the coasts and islands of the Arctic Sea, where they graze on the sprouting *Carices*, and on the withered grass or hay of the preceding year, which is at that period still standing and retaining part of its sap. Their spring journey is performed partly on the snow, and partly, after the snow has disappeared, on the ice covering the rivers and lakes, which have in general a northerly direction. Soon after their arrival on the coast the females drop their young; they commence their return to the south in September, and reach the vicinity of the woods towards the end of October, where they are joined by the males. This journey takes place after the snow has fallen, and they scrape it away with their feet to procure the lichens, which are then tender and pulpy, being preserved moist and unfrozen by the heat still remaining in the earth. Except in the rutting season, the bulk of the males and females live separately; the former retire deeper into the woods in the winter, whilst herds of the pregnant does stay on the skirts of the Barren Grounds, and proceed to the coast very early in the spring. Captain (Sir William) Parry saw deer on Melville peninsula as late as the 23rd of September, and the females with their fawns made their first appearance on the 22nd of April. The males in general do not go so far north as the females. On the coast of Hudson's Bay the Barren-Ground Caribou migrate farther south than those on the Coppermine River or Mackenzie River, but none of them go to the southward of the Churchill. The lichens on which the Caribou principally feed whilst on the Barren Grounds are *Cornicularia tristis*, *C. divergens*, and *C. ochrileuca*, *Cetraria nivalis*, *C. cucullata*, and *C. Islandica*, and *Cenomyce rangiferina*. ('Fauna Boreali-Americana.') In the isthmus of Boothia the Rein-Deer does arrived about the middle of April, the bucks nearly a month later; and herds of several hundreds were seen about the isthmus towards the end of May. Numbers of the fawns, which at that period are in a very weak state, are killed by the natives, who hunt them with their dogs; and the does themselves often fall victims to their attachment to their offspring. Captain James Ross states that the Rein-Deer feeds on the *Usneæ*, *Alectoriæ*, *Cetrariæ*, and other lichens in the early part of spring; but as the summer advances the young and tender grass fattens them so quickly that in August they have been killed with several inches thick of fat on their haunches. In this state the meat is equal to the finest English venison, but is most tasteless and insipid when in poor condition. (Appendix to Sir John Ross's 'Last Voyage.')

The Caribou travel in herds varying in number from eight or ten to two or three hundred; their daily excursions being generally towards the quarter from which the wind blows. The Indians kill them with bows and arrows or guns, sometimes approaching by means of a disguise, sometimes taking advantage of rocks or other shelter, and always greatly assisted by the curiosity and unsuspecting nature of the deer themselves. They also take the Rein-Deer in snares, or spear them as they are crossing rivers or lakes. The Esquimaux take them in traps ingeniously formed of ice and snow. A single family of Indians will sometimes destroy two or three hundred in a few weeks; and in many cases they are killed for the sake of their tongues alone. The reader will find a graphic account of the Esquimaux method of taking them in Captain Lyon's 'Private Journal,' p. 336; and a description of the deer found in use among the Chepewyans (Chippeways), in Hearne. Sir John Franklin relates the ingenious methods pursued by the Copper Indians and Dog-Ribs. Captain James Ross remarks that the natives of Boothia seldom hunt the Rein-Deer in the spring, and then the bow and arrow is the only mode of killing it; but in the autumn, as the animals return from the north in fine condition, they are destroyed in great numbers by parties of the natives driving them into the water, whilst others in canoes kill them with spears at their leisure.

Utility to Man.—To the Laplander particularly the Rein-Deer is all in all. According to Hoffberg, the mountaineer very often possesses three or four hundred or even a thousand head; the woodman very rarely above one hundred. As a domestic animal, yielding a quantity of the most delicious food, and occupying the place of the cow and the ox, it is invaluable. As a beast of burden its importance is equally great, and its organisation is adapted to the icy wastes, over which it forms the Laplander's sole medium of communication, no less than that of the camel is framed for those arid deserts which without the latter animal would be impassable. The weight which it can draw when harnessed to a sledge is said to be 300 lbs.; but 240 lbs. form the general limit of the burden. The tales told of its swiftness, when thus employed, would appear almost incredible if not so well attested as they are. In a race of three deer with light sledges started by Pictet, who went to the north of Lapland in 1769 to observe the transit of Venus, the first performed 3089 ft. 8 in. and $\frac{96}{100}$ in two minutes, making a rate of nearly 19 English miles an hour; the second went over the same ground in three minutes, and the last in three minutes twenty-six seconds. One is recorded to have drawn an officer with important dispatches, in 1699, 800 English miles in forty-eight hours; and the portrait of the poor deer, which fell dead at the end of its wonderful journey, is still preserved in the palace of Drottningholm in Sweden. Journeys of 150 miles in nineteen hours are said not to be uncommon.

To the natives of North America the Rein-Deer is only known as a beast of chase, but it is a most important one: there is hardly a part of the animal which is not made available to some useful purpose. Clothing made of the skin is, according to Richardson, so impervious to the cold, that, with the addition of a blanket of the same material, any one so clothed may bivouack on the snow with safety in the most intense cold of an arctic winter's night. The venison, when in high condition, has several inches of fat on the haunches, and is said to equal that of the fallow-deer in our best British parks; the tongue and some of the tripe are reckoned most delicious morsels. Pemmican is formed by pouring one-third part of melted fat over the pounded meat and incorporating them well together. The Esquimaux and Greenlanders consider the stomach or paunch, with its contents, a great delicacy, and Captain James Ross says that those contents form the only vegetable food which the natives of Boothia ever taste. (Richardson's 'Fauna Boreali-Americana.')



Rein-Deer (*Tarandus Rangifer*).

Highly excellent as an article of food, and useful domestically as this animal is, we do not think that it can ever be introduced with much success into the British Islands. Not that there would be much difficulty about the food for the deer; it is space that is wanting. A long succession of generations would be required before the migratory habits of the Rein-Deer could be got rid of, and possessing as we do the best venison, and the finest breed of horned cattle and horses, there seems no very good reason for repeating the experiments which have already been tried and have failed.

3. *Cervus Canadensis*, the Wapiti. This animal is the Wapiti Stag of Pennant, 'Arctic Zool.'; Wewaskiss of Hearne; Waskeesews, or Red-Deer, of Hutchins; Red-Deer of Umfreville; the Elk of Lewis and Clark; the American Elk of Bewick; Wapiti of Barton and Warden; Le Wapiti of F. Cuvier; the Wapiti (*C. Strongyloceros*) of Smith; Red Deer of the Hudson's Bay Traders; La Biche of the Canadian Voyageurs; Wawaskeesho, Awaskees, and Moostosh, of the Cree Indians (Richardson). It is also Le Cerf du Canada of Cuvier, who makes it the *C. Canadensis* of Gmelin (Buffon), and *C. Strongyloceros* of Schreber; and Cerf Wapiti of Lesson, who states it to be *C. Wapiti* of Mitchell and *C. major* of Ord. It may be also the Stag of Carolina of Lawson, but he describes it as "not so large as in Europe, but much larger than any fallow-deer;" and he says they are always fat with some delicate herbage that grows on the hills, whereas the modern travellers describe the Wapiti as frequenting the savannahs or the clumps of wood that skirt the plains. There is hardly any doubt that it is the Stag of America (*C. major Americanus*) of Catesby. "This beast," says the author last named, "nearest resembles the European red deer in colour, shape, and form of the horns, though it is a much larger animal and of stronger make. Their horns are not palmated but round, a pair of which weighs upwards of thirty pounds. They usually accompany buffaloes (Bisons), with whom they range in droves in the upper and remote parts of Carolina, where, as well as in our other colonies, they are improperly called Elks. The French in America call this beast the

Canada Stag. In new England it is known by the name of the Gray Moose, to distinguish it from the preceding beast (the True Elk) which they call the Black Moose." Richardson states that it is without doubt the Canada Stag of various authors; but, as F. Cuvier has observed, the want of a pale mark on the rump in Perrault's figure is sufficient to excite a doubt of its being the *C. Canadensis* of that author. Indeed he does not think it at all improbable that this figure is that of the *C. Macrotis*, which may hereafter prove to be an inhabitant of Upper Canada. Dr. J. E. Gray defines it as follows:—Red-brown; rump with a very large pale disc extending far above the base of the tail, and with a black streak on each side of it; male with hair of throat elongated, black with reddish tips.

Geographical Distribution.—Sir John Richardson says that this animal does not extend its range farther to the north than the 56th or 57th parallel of latitude, nor is it found to the eastward of a line drawn from the south end of Lake Winipeg to the Saskatchewan in the 103rd degree of longitude, and thence till it strikes the Elk River in the 111th degree. To the south of Lake Winipeg he thinks it may perhaps exist farther to the eastward. He adds that they are pretty numerous amongst the clumps of wood that skirt the plains of the Saskatchewan, where they live in small families of six or seven individuals, and that they feed on grass, on the young shoots of willows and poplars, and are very fond of the hips of the *Rosa blanda*, which forms much of the underwood in the districts which they frequent.

A small variety is described as a native of the plains of California and the upper parts of the river Missouri. It is very abundant and occurs in large herds.

The height of this animal at the shoulders is 4½ feet, more than a foot exceeding that of the common stag. All the upper parts and the lower jaw are of a somewhat lively yellowish-brown; a black mark from the angle of the mouth along the side of the lower jaw; a brown circle round the eye. The first antlers depressed in the direction of the facial line. Neck mixed red and black, with coarse black hairs descending from it like a dewlap, deeper in colour than the sides. From the shoulders to the hips French gray; a pale yellowish patch on the buttocks, bounded on the thighs by a black line; tail yellowish, 2½ inches long, whereas it is nearly 7 inches in the European Stag. The hair of a mean length on the shoulders, the back, the flanks, the thighs, and the under part of the head; that on the sides and limbs shorter, but the hair is very long on the sides of the head posteriorly and on the neck, particularly below, where they form the kind of dewlap above alluded to. On the posterior and outer aspect of the hind legs there is a brush of tawny hair which surrounds a narrow long horny substance. Ears white within and clothed with tufted hair, externally of the same colour as the neighbouring parts; a naked triangular space round the larger lachrymal sinus near the inner angle of the orbit. Hoofs small. Like the common stag, the Wapiti has a muzzle, upper canine teeth, and a soft tongue. The quality of the hair is brittle and there is a short wool beneath it. Richardson thinks that the Crees give it the name of Stinking Head on account of the large suborbital opening.

Hearne gives the Wapiti a character for stupidity surpassing that of all the deer kind. He says that they frequently make a shrill whistling and quivering noise, not very unlike the braying of an ass. Mr. Drummond, who saw many in his journeys through the plains of the Saskatchewan, informed Sir John Richardson that it does not bell like the English deer. F. Cuvier describes the cry as prolonged and acute, consisting of the successive sounds *a*, *o*, *u* (French), uttered with so much strength as to offend the ear.

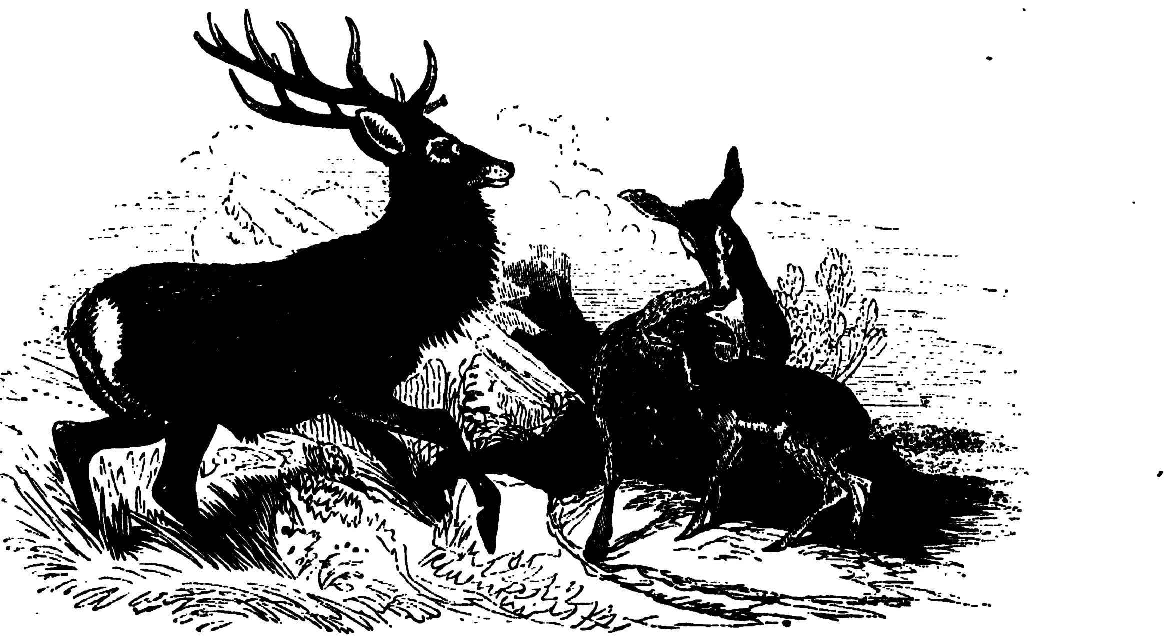
The flesh of the Wapiti is coarse, and little prized by the natives, principally on account of the fat being hard like suet. It wants the juiciness of venison, and resembles dry but small grained beef. Its hide, when made into leather after the Indian fashion, is said not to turn hard in drying after being wet, and in that respect to excel moose or rein-deer leather.

The velvety covering of the horns shrivels and is rubbed off in the month of October, at the commencement of the rutting season, but the horns themselves do not fall until the month of March or April.

The pair shed by 'Monkey' (one of the Wapiti kept by the Zoological Society of London in the Regent's Park), on the 4th March, 1837, weighed 26½lbs.

Wapiti (*Cervus Canadensis*).

That the Wapiti will live and thrive well and propagate in Great Britain there is now no doubt; but grand as the appearance of the animal is, it is not probable that it will be bred here to any great extent on account of the inferior quality of its venison.



Common Stag (*Cervus Elaphus*).

N.B. Mr. Smith makes a sub-genus of the True Stags under the name of *Elaphus*.

4. *C. Elaphus*, the Stag. It is the Common Stag, or Red Deer, of the English; Carw (Stag), Ewig (Hind), Elain (Young or Calf), of the ancient British; Le Cerf (Stag), La Biche (Hind), Faon (Young or Calf), of the French; Cervio, Cervia, of the Italians; Ciervo, Cierva, of the Spanish; Cervo, Cerva, of the Portuguese; Hirtz, Hirsch (Stag),

Hind (Hind), Hinde Kalb (Calf) of the Germans; Hart (Stag) and Hinde of the Dutch; Hjort, Kronhjort (Stag), and Hind, of the Swedes; Kronhjort, Hind, Kid, or Hind-Kalv, of the Danes; the *Cervus vulgaris*, Linnæus; *C. nobilis*, Klein; *Cervus*, Pliny; **'Ελαφός**, Aristotle; *Cervus Germanicus*, Brisson; *Tragelaphus*, Gesner; *Hippelaphus*, Johnston.

This noble species is a native of the forests of the whole of Europe and Asia where the climate is temperate. In England it is intimately blended with the old oppressive forest laws, which valued the life of a man at less than that of a stag, and with some of our legends of deadly feud: 'Chevy Chace,' for instance. The stag-hounds that formerly roused the deer on the moors of the west of England are at present dispersed, and although in Scotland villages have been depopulated to let it run wild, it is the rifle of the deer-stalker principally that now brings the stag down.

The Red Deer is distinguished by its brown colour. The rump has a pale spot extending rather above the upper surface of the base of the tail. They sometimes attain a great size. Pennant speaks of one that weighed 18 stones Scots, or 314 lbs., exclusive of the entrails, head, and skin. The Prince of Canino has described a Corsican variety as *Cervus Corsicus*. Buffon remarks of this species that he believes its small size depends on a deficiency of nourishment, for when removed to better pastures it becomes even bigger than the Common Stag.

5. *C. Barbarus*, the Barbary Deer, is chiefly distinguished from the Common Stag and the Algerian variety of it by its smaller size, stouter form, and more permanently-spotted fur. It is the Bush-Goat of the Moors, and inhabits the coasts of Barbary.

6. *C. Wallichii*, the Bara Singa, or Morl, is an Indian species. It is also found in Persia, where it is called Maral, Gevezu, or Gookoohee. It is the *Cervus Pygargus* of Hardwicke; also Jesrael, or Tailless Deer, and Red Deer, of India.

7. *C. affinis*, the Saul-Forest Stag, the Stroa or Tibetan Stag of Hodgson, the Bara Singha of the Hindoos. The bones are as heavy and as large as those of the Wapiti.

8. *C. Sika*, the Sika, is of a dark-brown colour, and has rather slender horns. It is a native of Japan.

9. *Dama vulgaris*, the Fallow-Deer. This well-known ornament of our parks is the Hydd (Buck), Hyddes (Doe), Elain (Fawn), of the ancient British; Le Daim (Buck), La Daime (Doe), Faon (Fawn), of the French; Daino (Buck), Damma (Doe), Cerbietto, Cerbietta (Fawn), of the Italians; Gama, Corza (Buck), Venadito (Fawn), of the Spanish; Corza (Buck), Veado (Fawn), of the Portuguese; Damhirsch of the Germans; Dof, Dof-Hjort, of the Swedes; Daae, Dijr, of the Danes; *Dama vulgaris*, Gesner; *Cervus palmatus*, Klein; *Cervus platyceros*, Ray; *Cervus Dama*, Linnæus.

It is not certain whether the common Fallow-Deer is the **Πρόξ** of Aristotle. Buffon and others are of that opinion; but M. Camus, who seems very well disposed to coincide with such opinion if he could, gives good reasons for doubt. Pennant considers the *Platycerata* of Pliny (book xi. c. 37), and the *Eurycerata* of Oppian ('Cyneg.' lib. ii., lin. 293), to have been our Fallow-Deer.

Fallow-Deer (*Dama vulgaris*).

Pennant, speaking of the two varieties, the spotted and the deep-brown, says, on the authority of Collinson, that they were introduced into this country by James I. from Norway, where he passed some time when he visited his intended bride, Anne of Denmark; and he remarks (citing Llywd), that one of the Welsh names of the animal, Geifr Danys, or Danish Goat, implies that it was brought from some of the Danish dominions. James, who observed their hardiness, brought them first into Scotland and thence to Enfield Chace and Epping, to be near his favourite palace, Theobalds. When Pennant wrote, they were, according to him, scarcely known in France, but were sometimes found in the north of Europe. In Spain, he observes, they are extremely large; and that they are met with in Greece, the Holy Land, and in China. For the two latter localities he quotes Hasselquist, who says he saw it in Mount Thabor, and Du Halde. Pennant goes on to state that in every country except our own these deer are in a state of nature unconfined by man; but they are, and for some time have been, confined in parks on the Continent as they are in England. In Moldavia and Lithuania they are said to be found wild. Cuvier observes that they have become common in all the countries of Europe, and that they appear to have come originally from Barbary. In a note to his last edition of the 'Règne Animal' he states, that since the publication of the second edition of his 'Ossemens Fossiles' he had received a wild Fallow-Deer (Daim) which had been killed in the woods to the south of Tunis.

Besides the varieties above mentioned, there are many others, as is generally the case with reclaimed or half-reclaimed animals. One variety is milk-white. Pennant remarks that in the old Welsh laws a Fallow-Deer was valued at the price of a cow, or, as some say, a he-goat. This species is represented on the sculptures of Nineveh.

10. *Panolia Eldii*, the Sungnai, is an Indian species.

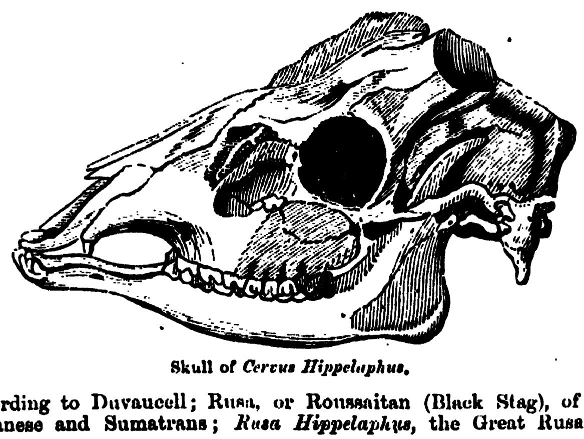
11. *Rucervus Duvaucellii*, the Bahrainga, is another Indian species. It is called the Spotted Deer of the Sunderbunds, and Barara Singha by Hardwicke. It is the *Cervus Elaphoides* of Hodgson. It inhabits reedy marshes and the islands of great rivers, never entering the mountains or forests. The tail is short, with no caudal disc and no heavy mane.

12. *Rusa Aristotelis*, the Samboo. It is the *Cervus Hippelaphus* of Ogilby, *Cervus unicolor* of H. Smith, Cerf de Coromandel of Cuvier, *Cervus Bengalensis* of Schirz, Daim Noir de Bengale of Duvaucell, the Samboo-Deer of Bennett, *Cervus heterocerus* of Hodgson. The last author describes four varieties of this animal. They are natives of various parts of India, and inhabit great forests and the mountains above them. They are not gregarious, and rut and drop their horns in spring.

13. *R. Dimorphe*, the Spotted Rusa, Gerver or Gower. Their colour is red-brown. They are confined to the saul-forests in India.

14. *R. Hippelaphus*, the Mijangan Banjoe. It is the *Cervus Hippelaphus* of Cuvier; Cerf Noir du Bengale, ou Hippelaphe, of F. Cuvier; Cerf d'Eau, ou Mejanganbanjoe, of the Malays of Java, according to Duvaucell; Rusa, or Roussaitan (Black Stag), of the Javanese and Sumatrans; *Rusa Hippelaphus*, the Great Rusa, of

Mijangan Banjoe (*Cervus* (*Rusa*) *Hippelaphus*).



Skull of *Cervus Hippelaphus*.

Smith; *C. Moluccensis* of Quoy and Gaimard; *C.* (*Rusa*) *Timorensis* of Müller.

The size and proportions of this animal are about those of the Common Stag, but its hair is rougher and harder, and when adult that of the upper part of the neck, of the cheeks, and of the throat is long, and forms a sort of beard and mane. In winter its colour is of a grayish-brown more or less deep; in summer it is of a brighter and more golden brown. The croup is a pale yellow, and the tail is brown terminated by rather long hair.

It is a native of Bengal, Sumatra, and the islands of the Indian Archipelago.

This is supposed to be the *Hippelaphus* of Aristotle; but G. Cuvier, who once was of that opinion, seems in the last edition of his 'Règne Animal' to consider that another species, *C.* (*Rusa*) *Aristotelis*, Cuvier, living in the north of India, is the animal alluded to by the Greek zoologist.

15. *R. equinus*, the Samboo. It is the *Rusa* of Raffles; the Eland or Elk of the Dutch sportsmen. It inhabits Sumatra and Borneo. It is of a plain brown colour.

16. *R. Peronii*, the Smaller Rusa, is a native of Timor and Luboc, Bavian and Ternate.

17. *R. Philippinus*, the Philippine Rusa, is the *C. Marianus* of Cuvier, the Cerf de Philippine of Desmarst. It is a native of the Philippines.

18. *R. lepida*, the Sundevall Rusa, is a native of Java. It is scarcely as large as a roe-buck.

19. *Axis maculata*, the Axis. It is the *Axis* of Pliny; *C. Axis* of Erxleben; *A. major* of Hodgson, also *A. medius* and *A. minor* of the same author; Cerf Cochon of Buffon; Spotted Axis or Chittra, Langna or Pada, or Spotted Porcine Deer, Thou or Spotted Porcine Axis, *A. medius*, or Spotted Hog-Deer, or Thou Langna of the Tarai, of Hodgson. In size and general form it nearly resembles the common Fallow-Deer. The skin is at all times of a rich fawn-colour spotted with white. Height at the shoulder 2 feet 6 or 7 inches. The distribution of the spots varies in different individuals. The ground-colour changes to nearly black along the back; the under parts are snow-white. Flanks, sides, shoulders, hind quarters, and part of the neck spotted as above mentioned. There is a broad dusky spot on the forehead, and a line of the same colour extends along the middle of the nose. The male has no canine teeth, nor has the female any horns; she is generally less in size than the male, and resembles him much in colour, but may be distinguished, it is said, by a white longitudinal line on the flanks. The young resemble the parents.

It is a native of India and the larger islands of the Indian Archipelago; very abundant in Bengal, and on the banks of the Ganges.

The Axis haunts the thick jungles in the vicinity of water, and the British sportsmen hunt it under the name of the Spotted Hog-Deer. It feeds in the night; and is timid, indolent, and mild, excepting when the females have young, and then the male is bold and fierce.

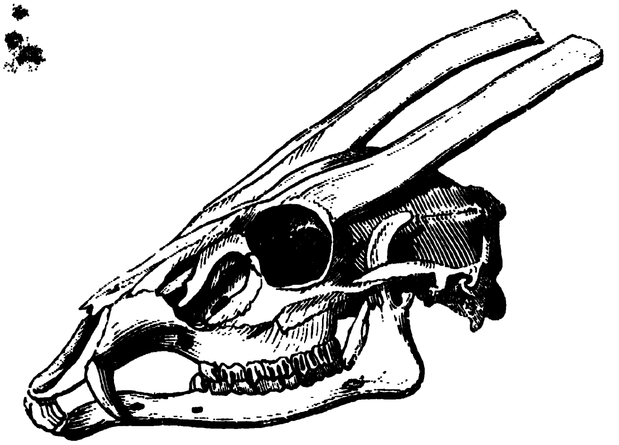
Axis (*Axis maculata*).

The Axis is easily domesticated, and in England has propagated freely in captivity. The species has been kept with success both in menageries and open parks, to both of which its form and colour make it an elegant ornament.

20. *A. pseudaxis*, the Spotted Axis. It is the *C. pseudaxis* of Gervais. It differs from *A. maculata* in having a series of spots in place of an oblique streak on the haunches.

21. *Hydaphus porcinus*, the Lugna Para, or Shgoriah. It is the *C. porcinus* of Sundevall; the *C. niger* of H. Smith; the Porcine Deer of Pennant; the Brown Porcine Axis of Hodgson; *C. Hippelaphus*, var. 3, of Cuvier. This species is easily known from the Axis by being lower on its legs, and having no distinct black dorsal streak, nor white streak on its haunches. The horns are generally short, with only short snags. They live in families, or small herds, on the plains of Hindustan. They are also found in Ceylon. Mr. Ogilby says they do not ascend mountains. The *C. Dodur* of Royle is probably a distinct species. *C. pumilis* of H. Smith is perhaps a variety.

22. *Cervulus vaginalis*, the Kijang or Muntjak. It is the *Cervus Muntjac* of Zimmerman; *Prox Muntjac* of Sundevall; *Cervus plicatus* of Forster; the Ribbed-Faced Deer of Pennant; the Chevreuil des Indes of Allamand.

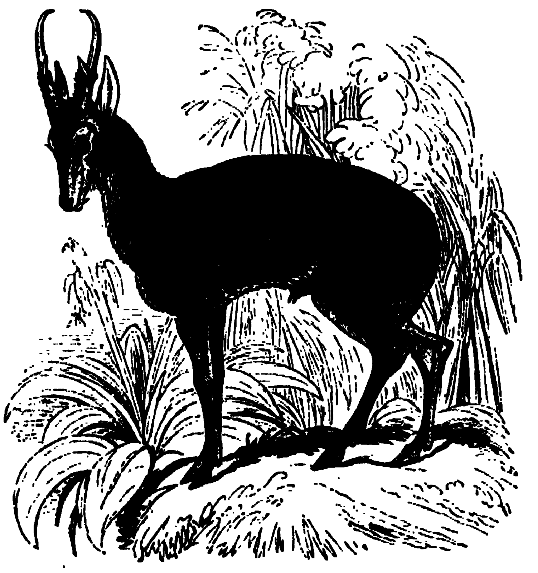


Skull of Muntjak (*Cervulus vaginalis*).

The height of the Muntjak at the shoulders is about 2 feet 2 inches; head pointed; eyes large, with lachrymal sinuses; ears rather large; tail short and flattened.

In the living animal there are on the face two rough folds of the skin, considerably distended and elevated, about an inch and a half apart above; and following the direction of the prominent part of the forehead they unite below, so as to mark the face with the letter V. In the dried subject the folds are contracted, and three distinct ribs appear, which suggested to Pennant the name of Rib-Faced Deer. General colour reddish-brown above; belly and front of the thighs pure white. The male has large canines in the upper jaw; the female has none, nor has she horns.

Dr. Horsfield, who has given the best account of this animal, states that "the Muntjak selects for its retreat certain districts, to which it forms a peculiar attachment, and which it never voluntarily deserts. Many of these are known as the favourite resort of our animal for several generations. They consist of moderately-elevated grounds, diversified by ridges and valleys, tending towards the acclivities of the more considerable mountains, or approaching the confines of extensive forests. Such districts are by no means uncommon in Java: they are covered with long grass, and shrubs and trees of moderate size, growing in groups or small thickets, and they generally intervene between cultivated tracts and the deep forests. Their vegetation is peculiarly adapted to afford our animal a very abundant



Muntjak (*C. vaginalis*).

supply of nourishment; their surface is covered with long grass (*Saccharum spicatum*), well known to persons who have visited the interior of Java by the name of Allang-Allang, and the groves and thickets abound with *Phyllanthus Emblica*, Linn.: these two plants constitute its principal food. They also produce many species of *Hibiscus*, *Grewia*, *Urena*, and other malvaceous plants, all of which are greedily eaten by the Kijang. . . . The Kijang is impatient of confinement, and is not fitted for the same degree of domestication as the stag. It is however occasionally found in the inclosure of natives and Europeans, but requires a considerable range to live comfortably: it is cleanly in its habits, and delicate in its choice of food. The flesh affords an excellent venison, which is often found on the tables of Europeans. The natives eat the males, and always present them in a conspicuous place in their feasts; but in consequence of some peculiarities in the habits of the females, they have an aversion to them as food."

23. *C. moschatus*, the Kegan or Kakr. It is the *Cervus Moschus* of Desmarest, *C. Ratwa* and *Styloceros Ratwa* of Hodgson, *Prox Ratwa* of Sundevall, *P. albipes* of Wagner, *P. styloceros* of Wagner, the Musk-Deer of Nepaul; the Jungle Sheep.

It is of a bright reddish-yellow colour, with the chin and gullet whitish. The hair is not ringed as in the following species.

The Ratwa are natives of India, where they live in forests, in the mountains, or at their bases. They live six or eight together. The horns fall in May. The females have bristly tufts ending in a knot instead of a horn.

24. *C. Reevesii*, the Chinese Muntjak, is of a grayish-brown colour, with short pale ringed hair. It is a native of China. Dr. J. E. Gray says ('Brit. Mus. Cat.'):—"The Earl of Derby has these three kinds (the three last species) at Knowsley, but they breed together, and it has hence become impossible to discriminate the males from the original species."

25. *Capreolus Caprœa*, the Roe-Buck. This animal is probably the Δορκὰς of Aristotle; *Iorcas* and *Dorcas* of Oppian; *Caprea* of Pliny (xi. 37); *Caprea*, *Capreolus*, *Dorcas*, of Gesner; *Capreolus* of Ray and of Sibbald; *Cervus Capreolus* of Linnæus; *C. minimus* of Klein; Iwrch (male), Iyrchell (female), of the ancient British; Le Chevreuil of the French; Capriolo of the Italians; Zorlito, Cabronzillo Montes, of the Spanish; Cabra Montes of the Portuguese; Rehbock (male), Rehgees, of the Germans; Radiur, Rabock, of the Swedes; Raaedijr, Raaebuk, of the Danes.

Its length is about 3 feet 9 inches; height before about 2 feet 3 inches; behind, 2 feet 7 inches. Weight from about 50 to 60 lbs. Length of horns from 8 to 9 inches; they are erect, round, and divided into three branches above; their lower part is deeply furrowed longitudinally. Those of a young buck in its second year are simple; in the third year a branch appears; the head is complete in the fourth year. In the winter the hair on the body is long, the lower part of each hair is ash-coloured, there is a narrow bar of black near the end, and the tip is yellow. On the face the hair is black tipped with yellow. The ears are long, of a pale yellow on the inside, and covered with long hair. In summer the coat is short and smooth, and of a bright reddish colour. The chest, belly, legs, and inside of the thighs, are yellowish-white; the rump is pure white, and the tail very short. On the outside of the hind legs, below the joint, is a tuft of long hair.

"The Roe-Buck was formerly very common in Wales, in the north of England, and in Scotland, but at present the species no longer exists in any part of Great Britain, except in the Scottish Highlands." Such is the locality given by Pennant when he wrote; and he adds that, according to Dr. Mouffett, it was found in Wales as late as the reign of Queen Elizabeth, and in great plenty in the Cheviot Hills, according to Leland, in that of Henry the VIII. That at one time the Roe inhabited the southern parts of the kingdom is clear, if the information given to the editor of the last edition of the 'British Zoology' is correct, for that states the discovery of seven or eight horns of the Roe in the peat beds near Romsey, in Hampshire, together with the complete head of a beaver, with the teeth entire. In Ireland the animal is not known. They are frequent in France, and are found in Italy, Sweden, Norway, and Siberia. Pennant, who gives these localities, says that the first that are met with in Great Britain are in the woods on the south side of Loch Rannoch, in Perthshire; the last in those of Langwal, in Caithness; but that they are most numerous in the beautiful forests of Invercauld, in the midst of the Grampians. They are still comparatively plentiful in Scotland. Sir James Carnegie had a battue, in which forty were killed. Sir William Jardine states, that south of the Forth they are now very rare, one or two wilder parks only possessing a few; but frequent traces of their former abundance are found in the border counties, remains and skeletons being almost yearly disinterred from most of the larger peat mosses. The same author speaks of its frequency in many European countries, Germany, Silesia, &c. ('Naturalist's Library,' Mammalia, vol. iii.)

The Roe does not keep in herds, but only congregates in families in the lower coverts and less wild woods. The female goes with young five months, and produces two fawns at a birth, and these she conceals from the buck. They are said to live twelve or fifteen years, and to be able to reproduce the species at the age of eighteen months. Pennant observes that it is a tender animal, and quotes Buffon, who says that in the hard winter of 1709 the breed was almost extinguished in Burgundy, and many years passed before it was restored again. It is generally killed—either in the covert or by the sportsman, who waits outside while the copse or wood is driven—with shot. It falls very readily, and often without being apparently severely struck; we have heard instances of their being knocked over with comparatively small shot. As soon as it is down the throat is cut, and the animal is hung up by the hind legs on the fork of some tree to bleed.

Roe-Buck (*Capreolus Dorcas*).

Herbage and tender shoots of underwood are the food of the Roe in the summer. They are said to be very fond of the *Rubus saxatilis*, called in the Highlands the Roe-Buck Berry. In winter, when the ground is covered with snow, they browse on the tender branches of the fir and the birch. (Pennant.)

The flesh is delicate food when well killed, and the horns are used for handles of carving-knives, &c.

Pennant states that in the old Welsh laws a roe-buck was valued at the same price as a she-goat.

26. *C. Pygargus*, the Ahu. It is the *Cervus Pygargus* of Pallas, *Cervus Ahu* of Griffith, the Siaga of the Tartars, Dikaja Kosa of the Russians, Tailless Roe and Tailless Deer of Pennant and Shaw. It is a native of Central Asia.

27. *Blastocerus paludosus*, the Guazupuco. It is the *Cervus Mexicanus* of Goldfuss, *C. dichotomus* of Illiger. It is a native of South America.

28. *B. campestris*, the Mazame or Guazuti. It is the *Cervus bezoarticus* of Linnæus, *C. campestris* of F. Cuvier, *C. leucogaster* of Goldfuss, the Biche de Pampas of Cuvier. It is a native of South America in Northern Patagonia. It is exceedingly abundant, in small herds, throughout the countries bordering the Plata. Mr. Darwin describes the odour of the buck as quite overpowering, from its disagreeable character.

29. *Furcifer Antisiensis*, the Tarush or Taruga, is a native of South America, in the Bolivian Alps.

30. *F. Huamel*, the Guemul. It is the *Auchenia Huamel* of H. Smith, the *Camelus Equinus* of Leuckart, *Cervecus Andicus* of Lesson, the Cloven-Footed Horse of Shaw. It is a native of the east coast of South America.

31. *Cariacus Virginianus*, the American Deer. It is the *Dama Virginiana* of Ray, *Cervus Virginianus* of Gmelin, *C. Strongyloceros* of Schreber, the Virginian and Mexican Deer of Pennant, the Cerf de la Louisiane of Cuvier, the Cariacou of Buffon. The tail of this animal, like the rest of its body, is fulvous, above the tip it is black, but beneath white, and is carried erect when running. They inhabit the Oregon, and are found to be most numerous near the coast of the Pacific Ocean. Their range on that coast is up to 15° N. latitude. At the Umqua, in latitude 43° they give place to the Black-Tailed Deer. "We believe that the same species of deer inhabits all the timbered or partially timbered country between the coast of the Atlantic and Pacific Oceans." (Gray.)

32. *C. Mexicanus*, the Mexican Deer. Tail fulvous gray. Not well known. Inhabits Mexico.

33. *C. leucurus*, the White-Tailed Deer. It is the *Cervus leucurus* of Douglass, *C. campestris* of F. Cuvier. Various writers on America have called it by the following names: Roe-Buck (Dobbs), the Fallow or Virginian Deer (Cook's Third Voyage); the Long-Tailed Jumping Deer (Umfreville); Deer with small horns and long tail (Gass.); Long-Tailed Red Deer, Small Deer of Pacific, Common Red Deer, and Common Fallow-Deer with long tails (Lewis and Clark); Jumping Deer (Hudson's Bay Traders); Chevreuil (Canadian Voyageurs); Mowitch (Cree Indians).

This species is not found on the east side of the Rocky Mountains farther north than latitude 54° N., nor is it found in that parallel east of 105° W. longitude. Mr. Douglass says, "it is the most common deer in the district adjoining the river Columbia, more especially on the fertile prairies of the Cowalidoke and Multnomah rivers, within 100 miles of the Pacific Ocean."

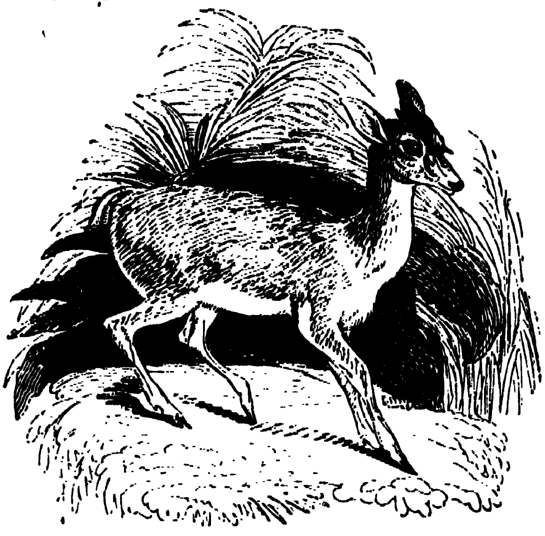
34. *C. nemoralis*, the Cariacou Deer. It is the Cerf Blanc or Cerf des Paletuviers of Cuvier, Chevreuil d'Amérique of Daubenton, Biche des Savannes of Buffon. It is a native of the shores of the Mexican Gulf and of Guyana. (Baillon.)

35. *C. punctulatus*, the Californian R[illegible]. Dr. J. E. Gray says, "There is a female of this species in the Zoological Gardens; it is much smaller and darker than *C. Virginianus*, and it differs in the hair being dark, with a distinct yellow subterminal band. It is a native of Columbia, and at best a doubtful species."

36. *C. Lewisii*, the Black-Tailed Deer. It is the *Cervus Lewisii* of Peale. A native of California between the Columbia River and the Umqua. It is seldom seen east of the Cascade Mountains. It never elevates its tail in running, and viewed from behind shows two narrow white lines of hair, instead of the large white and elevated tail of the Virginian Deer.

37. *C macrotis*, the Mule-Deer. It is rather larger than *C. Virginianus*, having more the general aspect of the Wapiti. It is destitute of the black submaxillary marks of *C. Lewisii* and *C. Virginianus*. It is most abundant on the eastern slope of the Rocky Mountains, and delights in rocky hills covered with cedars and fir-trees.

38. *Coassus nemorivagus*, the Gauzu-viva. It is the *Cervus Nemorum* of Desmarest, *C. simplicicornis* of Illiger, *C. margivorus* of Schrank. This delicate little deer is only 26 inches in length. Its aspect is said to approach that of the sheep. The lachrymal sinus is said to be nearly imperceptible.



Gauzu-viva (*Coassus nemorivagus*).

The lower part of the head and lips whitish. Space round the eyes, inside of fore legs, and from lower part of breast to buttocks whitish-cinnamon. Neck and all the other parts brownish, approaching to grayish, each hair being tipped with white. Horns short. It is a native of the Brazils.

Cuguacu-ete (*Coassus rufus*).

39. *C. rufus*, the Cuguacu-ete or Pita. It is the *Cervus rufus* of F. Cuvier, *C. dolichurus* of Wagner, *Subulus Americanus* of J. Brookes, *Subulo rufus* of H. Smith.

Its height is about 29 inches; general colour reddish-brown; inside of ears (hairs short), space round the lips, lower part of head and tail, hind part of belly, buttocks, and inside of fore legs to knees, whitish. Females without horns. Nearly of the same reddish tint, with a white spot above the nose and on the upper lip.

It lives in the low moist woods of South America, in large herds, and as ten females are seen for one male, it is supposed that their appearance gave currency to the report of a form of deer on the New Continent without horns. They are very fleet only for the first [illegible] for they are soon run down by dogs, and are sometimes captured by the lasso and balls.

40. *C. superciliaris*, the Eye-Browed Brocket, differs chiefly from the two last in the form of the muffle, and in the presence of a white streak over the eyes. It is a native of the Brazils.

41. *C. auritus*, the Large-Eared Brocket. It is also a native of the Brazils.

42. *Pudu humilis*, the Venada. It is the *Cervus humilis* of Bennett; *Capra Pudu*, Molina; *Antilocapra Pudu*, Lesson; *Antilope Dicranocerus Temamazama*, H. Smith; *Cervus Macatlchichiltic*, Seba; Mazame of Hernandez. It is a native of Chili.

Fossil Cervidæ.

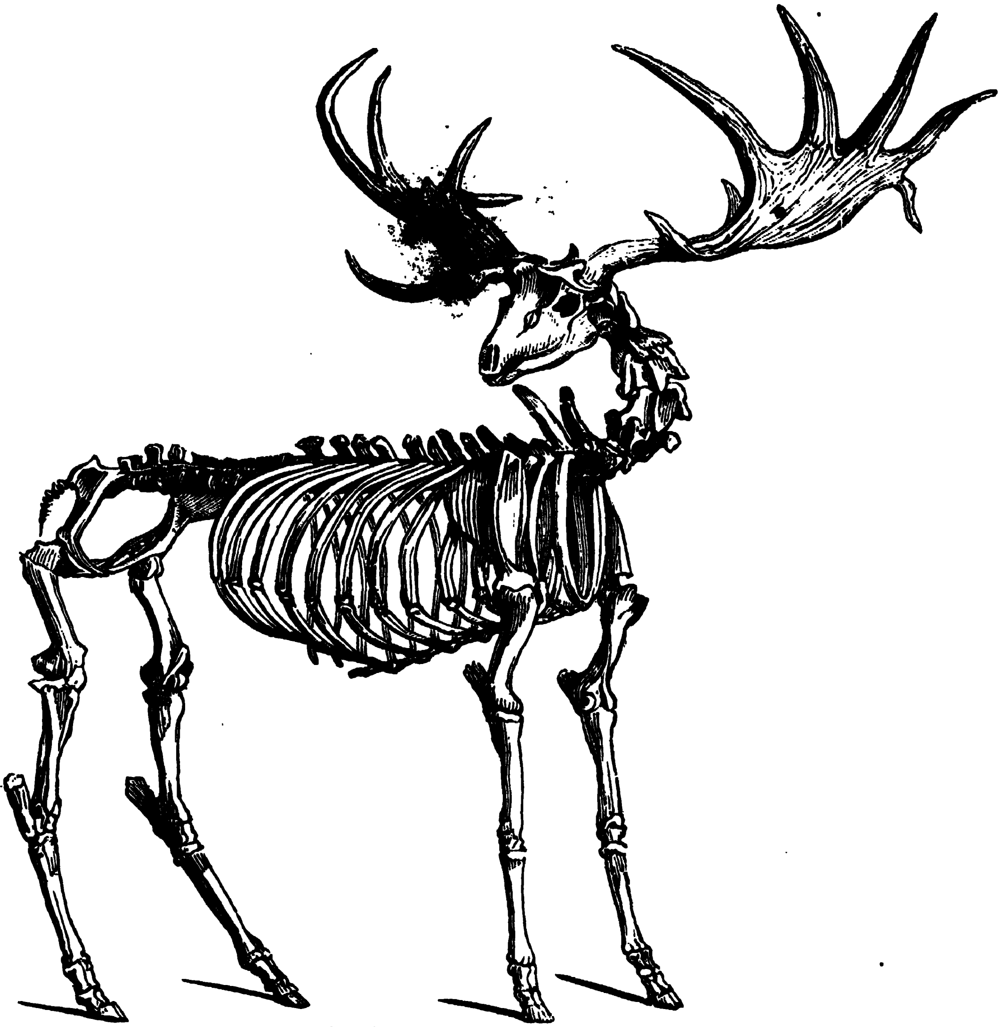
The remains of Deer are sufficiently numerous in beds of the third period of the Tertiary Series and in caverns. Thus, in the cave at Kirkdale, Dr. Buckland found evidences of at least three species, the smallest being very nearly of the size and form of a fallow-deer, the largest agreeing in size with the elk, but differing in form; and a third, of intermediate size, approaching that of a large stag or red-deer. The skeletons of animals found in the recent shell-marls of Scotland, according to Sir C. Lyell, all belong to species which now inhabit or are known to have been indigenous in Scotland. Several hundred, he observes, have been procured within the last century from five or six small lakes in Forfarshire, where shell-marl has been worked. Those of the Stag (*Cervus Elaphus*) are stated to be the most numerous; and if the others be arranged in the order of their relative abundance they will follow, according to Sir C. Lyell, nearly thus:—Ox, boar, horse, dog, hare, fox, wolf, and cat. The beaver, he adds, seems very rare; but it has been found in the shell-marl of Loch Marlie in Perthshire, and in the parish of Edrom in Berwickshire.

The most remarkable of the Fossil *Cervidæ* found in the British Islands is the *Megaceros Hibernicus*, the gigantic Irish Deer. This animal has been called by various names, of which the following are the most common:—*Cervus platyceros altissimus*, Large Irish Deer, Molyneux; *Cervus fossilis*, Goldfuss; Cerf à Bois Gigantesque, Cuvier; the Fossil Elk of Ireland, Parkinson; *Cervus Hibernus*, Desmarest; *Cervus megaceros*, Hart; Fossil Dama of Ireland, Hamilton Smith.

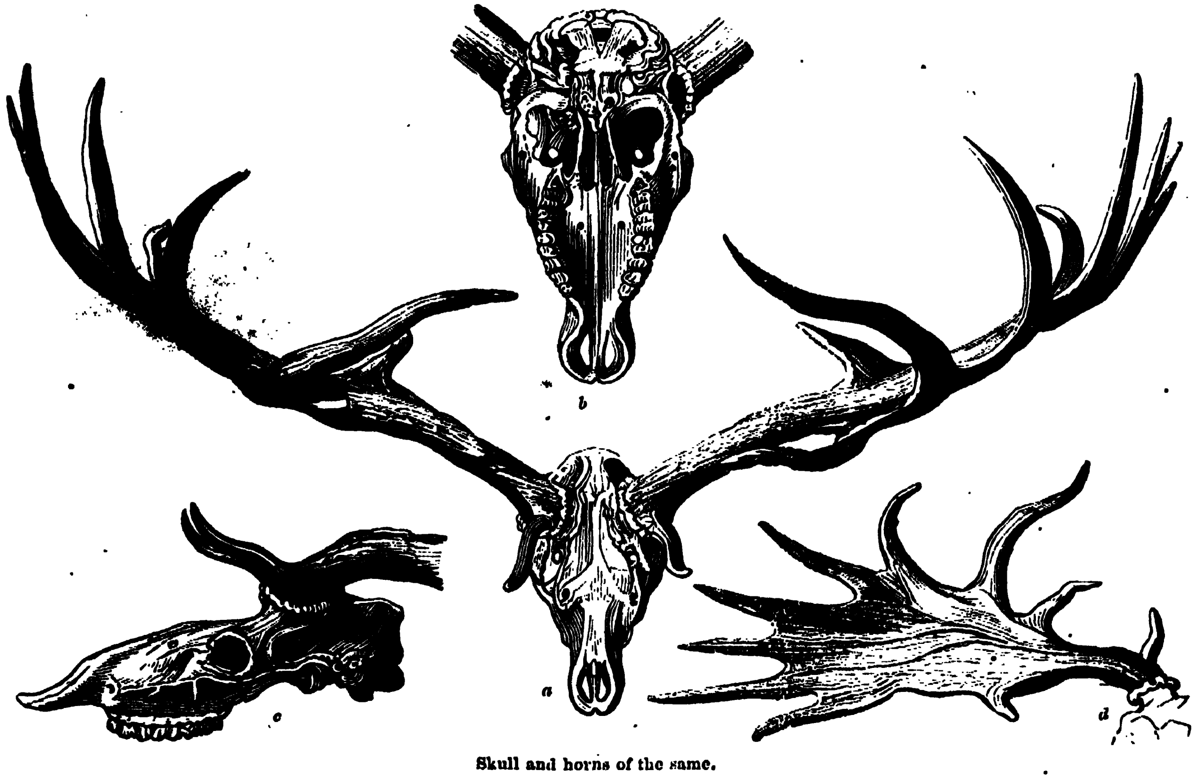
Dr. Molyneux, to whom we owe the first account of the remains of this animal, supposed it to be the American Moose. On this point Professor Owen says, "The great extinct Irish Deer surpassed the largest Wapiti or Elk in size, and much exceeded them in the dimensions of the antlers. The pair first described and figured in the 'Philosophical Transactions' measured 10 feet 10 inches in a straight line from the extreme tip of the right to that of the left antler; the length of each antler, from the burr to the extreme tip in a straight line, was 5 feet 2 inches, and the breadth of the expanded part, or palm, was 1 foot 10½ inches. Dr. Molyneux, after giving the dimensions of the fossil head and its noble attire, says—'Doubtless all the rest of the parts of the body answered these in due proportion,' and he infers the amount of the superiority of the great Irish Deer over the 'fairest buck' accordingly."

"Recent discoveries of the entire skeleton of the Megaceros however have shown that the proportions of the trunk and limbs to the vast antlers were not the same with which we are familiar in the existing Deer best provided with these weapons, but that the antlers were both absolutely and relatively larger in the [illegible] extinct species. This in fact constitutes one of its best characteristics, and involves other differences in the form and proportions of its osseous framework. One of the modifications in the skeleton of Megaceros, which relates to the vast weight of the head and neck, is the stronger proportions of its limbs; and another and more striking character is the great size of the vertebræ of the neck, which form the column immediately supporting the head and its massive appendages. The extent of these modifications may be appreciated by the following dimensions of the skeleton of the Megaceros and of that of the Great American Moose (*Alces palmata* and *Americana*):—

	Megaceros.			Alces.		
	Ft.	In.	Lin.	Ft.	In.	Lin.
Length of the trunk from the 1st rib to the end of the ischium	6	3	3	5	0	0
Height from the ground to the top of the longest dorsal spine	6	0	0	5	6	0
Length of the fore-leg from the top of the scapula in a straight line	5	7	0	5	4	6
Length of hind leg from the head of the femur in a straight line	4	9	3	4	10	9
Circumference of fourth cervical vertebra . . .	1	10	0	1	0	0
Span of antlers between the extreme tips . . .	8	0	0	4	0	0"



Gigantic fossil Deer (*Megaceros Hibernicus*).



Skull and horns of the same.

a, Front view of the whole head; *b*, the skull seen from below; *c*, profile of the same; *d*, horn, on a less scale, seen perpendicularly to its posterior surface.

The weight of the skull and antlers of the *Megaceros* in the Museum of the College of Surgeons in London is 76 lbs., whilst another exists in Dublin which weighs 87 lbs. The average weight of the skull, without the horns or lower jaw, is 5¼ lbs. From this fact we may form some idea of the enormous size of the antlers, which seem to have obeyed the same periodical law as those of all existing deer. When it is recollected that all the matter of these antlers must have been drawn from the blood carried to the head by the carotid arteries in the course of a few months, our wonder may well be excited at the special activity of the capillary circulation of these parts.

The question has been somewhat eagerly discussed, as to whether the *Megaceros* existed within the historical period. On this point Professor Owen has the following remarks :—

"Is there any evidence, it may be asked, that the *Megaceros* coexisted with the human race, or that its extinction was the result of man's hostility? Dr. Molyneux ('Phil. Trans.,' xix. p. 490) says that its extinction in Ireland has occurred 'so many ages past, as there remains among us not the least record in writing, or any manner of tradition, that makes so much as mention of its name; as that most laborious inquirer into the pretended ancient but certainly fabulous history of this country, Mr. Roger O'Flaherty, the author of 'Ogygia,' has lately informed me.'

"The term Shelch, in the romance of the 'Niebelungen,' written in the 13th century, and there applied to one of the beasts slain in a great hunt a few hundred years before that time in Germany, has been cited by Goldfuss, and subsequently by other naturalists, as probably signifying the *Megaceros*, just as the Halb-Wolf of the same 'Lied' has been conjectured to be the Hyæna.

"The total silence of Cæsar and Tacitus respecting such remarkable animals, renders their existence and subsequent extirpation by the savage natives a matter of the highest improbability; and it has been well observed by Dr. Buckland, that 'the authority of the same romance would equally establish the actual existence of giants, dwarfs, and pigmies, of magic turn-caps—the using of which would make the wearer become invisible—and of fire-dragons, whose blood rendered the skin of him who bathed in it of a horny consistence, which no sword or other weapon could penetrate.'

"Some appearances in the bones themselves of the *Megaceros*, and perhaps an undue confidence in the vague statements of their discovery with remains of the existing deer, hog, and sheep, in peat-bogs, have led to the opinion that the Gigantic Deer existed within the time of man. Dr. Hart cites the fact of the discovery of a human body in gravel, under eleven feet of peat, soaked in the bog-water, which was in good preservation, and completely clothed in antique garments of hair, which it had been conjectured might be that of our fossil animal. But if any *Megaceros* had perished, and left its body under the like circumstances, its hide and hair ought equally to have been preserved. Except however the solitary instance of fat or adipocire in the shaft of one of the bones discovered by Archdeacon Maunsell, not a particle of the soft parts of the animal seems ever to have been found. Dr. Hart conceives that 'more conclusive evidence on this question is derived from the appearance exhibited by a rib, in which he discovered an oval opening near its lower edge, with the margin depressed on the outer, and raised on the inner surface, round which there is an irregular effusion of callus. This opening,' he says, 'appears evidently to have been produced by a sharp-pointed instrument which did not penetrate so deep as to cause the animal's death, but which probably remained fixed in the opening for some length of time afterwards; in fact, such an effect as would be produced by the head of an arrow remaining in a wound after the shaft was broken off.' (Op. cit., p. 29.)

"But a conical arrow-head, with a base one inch in diameter, sticking in a rib, with its point in the chest, must have pierced the contiguous viscera, and rankling there have excited rapid and fatal inflammation. The evidence of the healing process in the bone would rather show that the instrument which pierced the rib had not been left there to impede the operations of the 'vis medicatrix naturæ.' A formidable branch of the formidable antler is as well suited to inflict such a wound as the hypothetical arrow; and if the combative instincts of the rutting stag rightly indicate the circumstances under which the wound of the *Megaceros* was inflicted, they would be those which best accord with the actual evidence of recovery from it."

Although the remains of this animal have been found principally in Ireland, they have also been dug up in the Isle of Man, in Scotland, and found in several of the ossiferous caverns of England. This discovery is interesting, as from the position in which the remains of the *Megaceros* have been found, it establishes the contemporaneity of this animal with the Mammoth, Rhinoceros, and other extinct *Mammalia* of the period of the formation of the newest tertiary fresh-water fossiliferous strata.

In the cavern of Kent's Hole, near Torquay, the base of an antler, fossil, and partly gnawed, has been found. It does not belong to *Megaceros*; and Professor Owen has referred it to a genus and species which he calls *Strongyloceros Spelæus*, Gigantic Round-Antlered Deer. "If the trunk and limbs bore the same proportions to the head and antlers as in the Wapiti and Red Deer, as most probably they did, the species indicated by this remarkable fragment of antler must have been the most gigantic of our extinct English Cervine animals." (Owen.)

Besides these, the remains of *C. Elaphus*, the Red Deer, *C. Tarandus*, the Rein-Deer, *Dama vulgaris*, the Fallow-Deer, *Capreolus Capræa*, the Roe-Buck, have all been found in various parts of the British Islands. Amongst the bones found in Kirkdale are those of a small deer, which Professor Owen calls *Cervus Bucklandi*.

Remains of Deer occur in other ossiferous caverns besides those of Great Britain, as in the Muggendorf caverns, the Grotte d'Echenoz, and that on the banks of the Meuse, at Chockier; as well as in the osseous breccias of Gibraltar, Cette, Nice, Corsica, and Antibes. M. Bertrand de Doue found, among the bones entombed in and beneath volcanic matter near St. Privat d'Allier (Velay), a large proportion of remains, referrible to at least four undetermined species of *Cervi*, in company with *Rhinoceros leptorhinus* and *Hyæna spelæa*; and M. Robert extracted from the ferruginous beds at Cussac (Haute-Loire) the bones of seven species of deer (to two of which he assigns the names of *Cervus Solilhacus*, and *C. dama Polignacus*), accompanied by the bones of the antelope, *Bos Urus* and *B. Velaunus*, two species of horse, *Elephas primigenius*, *Rhinoceros leptorhinus*, and *Tapir Arvernensis*. Among the fossil species enumerated we find, under section *a*, *Cervus giganteus*, *C. euryceros*, and *C. Americanus*; under section *β**, *C. Guettardi*; and under *β*** *C. Hibernus* and *C. Somonensis*.

Captain P. Cautley, in his paper 'On the Remains of Mammalia found in the Sewalik Mountains, at the southern foot of the Himalayas, between the Sutluj and the Ganges,' enumerates, among the fine collection of bones found by him, those of the elk and several varieties of deer. In the district between the Jumna and the Ganges he obtained the remains of more species of deer than one in the marl or clay conglomerate, described as consisting of fragments of indurated clay, cemented by clay, sand, and carbonate of lime. Professor Kaup discovered the bones of the following deer :—*Cervus anocerus*, *C. trigonocerus*, *C. dicranocerus*, and *C. curtocerus*—in the sand resting upon the calcaire grossier in Rhenish Hesse, in company with *Dinotherium*, &c. &c. Deer therefore may be considered to have existed in the second and third tertiary periods, namely, the Miocene and Pliocene periods of Lyell.

CERVUS. [CERVIDÆ.]

CESTRA'CEÆ, or CESTRI'NÆ, a natural order of plants belonging to the class of Monopetalous Exogens. It is nearly related to *Solanaceæ*, and is sometimes made to form a tribe of that order. It has the following characters:—Limb of corolla plicate, valvate or induplicate in æstivation; calyx 5-toothed; corolla funnel-shaped, 5-lobed, regular; tube elongated, limb usually spreading; stamens 5; anthers dehiscing lengthwise; ovarium seated on a cupulate disc; pericarp capsular or baccate; placentas adnate to the dissepiment; embryo nearly straight, with a cylindrical radicle, and roundish leafy cotyledons. It embraces the genera *Cestrum*, *Dunalia*, *Meyenia*, *Dartus*, *Vestia*, *Lessea*, *Fabiana*, *Laureria*, *Lamarkia*. In the second edition of the 'Natural System,' Dr. Lindley recognises the order *Cestraceæ*, and adds, "I do not attempt to characterise this assemblage of plants, being uncertain what its real peculiarity is. According to Schlechtendahl, it has all the characters of *Solanaceæ*, except that the embryo is nearly straight, and the cotyledons foliaceous. To this however it is possible that the valvate æstivation of the corolla ought to be added; but I am by no means sure that the species of *Periphragmos* of the 'Flora Peruviana,' with winged seeds, ought not to be included, although, as they have an imbricated æstivation, and a tricarpellary fruit, they are placed in *Polemoniaceæ*. These plants, which are very different from those of Jussieu's *Cantuas*, especially *C. quercifolia*, have much the habit of *Lycium* as well as *Vestia*. If they really do belong to *Polemoniaceæ*, they must be considered a connecting link between that order and *Cestraceæ*." The genera then recognised by Lindley were, *Cestrum*, *Vestia*, *Lessea*, *Fabiana*. In the 'Vegetable Kingdom,' Dr. Lindley has dropped the order *Cestraceæ*.

The genus *Cestrum* has a tubular calyx, [illegible], very short, obsoletely 5-toothed; corolla funnel-shaped, with a long slender cylindrical tube; a roundish throat and a flat limb, with ovate equal segments; filaments the length of the tube; anthers inclosed, being roundish, 2-celled, [illegible] seeded. *C. venenatum* is a large woody bush which grows at the Cape of Good Hope, in Houtinqua Land, and elsewhere. The flowers are arranged in axillary clusters; the corolla has a reddish tube and a white limb, and emits a perfume resembling Jasmine flowers. A decoction of the bark reduced to an extract by evaporation is employed by the Hottentots to poison their arrows. It is said to be a speedy poison, and is also employed to destroy wild beasts by mixing with their food. *C. macrophyllum* and *C. noctuum* have similar properties. *C. Hediunda* and *C. lamifolium* are febrifuge, and are applied extensively as astringents in Peru. About 50 species of *Cestrum* have been described. They are all of them natives of North and South America, and the West India Islands, and are known by the common name of Bastard Jasmines. They are easily cultivated, and will grow in any rich light soil, and are easily propagated by cuttings, which should be placed under a hand-glass in heat. The species of the allied genera require the same treatment.

(Don, *Gardener's Dictionary*; Lindley, *Flora Medica*; Lindley, *Vegetable Kingdom*.)

CESTRUM. [CESTRACEÆ.]

CESTUM. [ACALEPHÆ.]

CETACEA, an order of Aquatic Mammals with fin-like anterior extremities, the posterior extremities being absent, or rather, having their place supplied by a large horizontal caudal fin or tail; without an external ear, without hair on their external integument, and the cervical bones so compressed as to leave the animal without any outward appearance of a neck. This order comprises the Whales, the largest animated forms in existence. Some of the genera composing it are phytophagous, or plant-eaters; others are zoophagous, or animal-eaters.

The Cetaceous Mammals, whose abode is either in the sea or the great rivers, resemble Fishes so closely in external appearance that it is hardly to be wondered at that not only the vulgar, but even some of the earlier zoologists, looked upon them as belonging to that class. This notion is kept alive to the present day in the announcements of the comparative success of those ships which are employed in the Whale Fishery; for not only is it conveyed by that general term for the capture of whales, but by statements that one ship has arrived with three fish, another with four fish, a third with one fish, &c.

If we turn to the Sacred Scriptures we find the Hebrew words Than and Thannin, which have been translated by the words Κῆτος (the word used by Æneas Gazæus to designate the fish out of whose belly Hercules is said to have escaped after having been swallowed) and 'whale.' Lycophron terms the marine animal that so disposed of Hercules when he was shipwrecked, *κάρχαρος κύων*, a shark.

The Septuagint translates the Hebrew words above noticed, *τὰ κήτη τὰ μέγαλα*, in the 21st verse of the first chapter of Genesis. The same Greek word is used in the 17th verse of the first chapter of Jonah. In the book of Job (vii. 12), and in that of Ezekiel (xxxii. 2), the translation uses the term *δράκων*. In Matthew (xii. 40), where the swallowing up of Jonah is alluded to, *κῆτος* is employed.

In Barker's 'Bible' (1615) the passage in Genesis is translated, "Then God created the great whales," much the same as it stands in the version now read in our churches, "And God created great whales."

The other passages are translated in Barker's 'Bible' as follows:—Jonah (i. 17), "Now the Lord had prepared a great fish to swallow up Jonah: and Jonah was in the belly of the fish three days and three nights:"—Job (vii. 12), "Am I a sea or a whale fish, that thou keepest me in ward?"—Ezekiel (xxxii. 2), "Thou art like a lyon of the nations, and art as a dragon in the sea;" in a note 'or whale' is added:—Matthew (xii. 40), "For as Jonas was three days and three nights in the whale's belly," &c.

In the version now used in our churches the passage in Jonah is verbatim the same as in Barker; that in Job is thus rendered, "Am I a sea, or a whale, that thou settest a watch over me?"—that in Ezekiel, "Thou art like a young lion of the nations, and thou art as a whale in the seas:"—that in Matthew is identical with the passage in Barker.

These are merely cited as examples: there are other passages in the Old Testament in which the words whale and *κῆτος* occur in the English and Greek versions. It would be beside the present question to enter into the discussion whether the whale was meant, or a crocodile, as some will have it, in the verses above quoted; it is sufficient for our purpose to show the commonly received opinion that a whale was a fish.

In the Index to Pliny's 'Natural History' we find the Whales treated as Fishes, "Balænarum Piscium Consideratio," "Balæna piscis," &c.; but in the work itself the *Balæna* and *Physeter* are noticed as *Beluæ*, and a fair account is given of their spouting and general habits. The 7th chapter of his ninth book, indeed, is headed "An spirent pisces, an dormiant;" but in that chapter he expressly states that neither whales nor dolphins (balænis nec delphinis) have gills, but breathe by means of fistulæ, or blow-holes, which appertain to the lungs.

Aristotle, whose great zoological work Pliny had closely studied, was certainly aware of the broad distinction between the Whales and Dolphins (the position of whose blow-holes he mentions), and Fishes.

Gesner separated the Whales from the Fishes, including them in a distinct order of marine animals. Aldrovandi separated them also, though they appear in the same volume, the title of which is 'De Piscibus Libri V.: De Cetis Liber Unus.' Johnston gives them a separate chapter at the head of his book 'De Piscibus.'

Ray, in his 'Synopsis Methodica Piscium' (1713), observes that the term 'fish' is extended, even by the learned of our country, to the bloodless aquatics, as they were then termed, *Exanguia aquatica*, such as *Crustacea*, *Testacea*, and *Mollia*, or Shellless Mollusks. On the other hand, some, he remarks, not only exclude those *Exanguia aquatica*, but also the *Cetacea* ("Cetaceum genus, seu Belluæ Marinæ"), contending that no other animals can justly be termed fishes except those which breathe by means of gills, and have but one ventricle to the heart. With these last Ray agrees, and expresses his own opinion, that, if we speak properly and philosophically, the name of Fish should be restricted to such last-mentioned animals only, and points out the absence of any relationship of the "Pisces Cetacei dicti" with the true fishes; adding, that with the exception of the place where they spend their lives, the external figure of their body, their hairless skin, and their natatory progression, the *Cetacea* have hardly anything in common with the true fishes, but in other respects agree with the viviparous quadrupeds.

Nevertheless, that he may avoid dissent from received opinions and the appearance of paradox, Ray declares that he will not innovate, but consider the Cetaceous Animals as Fishes; and he proceeds to define what a fish is, thus: An aquatic animal having blood, wanting feet, swimming with fins, covered either with scales or with a naked, smooth, hairless skin, passing its life in the waters, and never voluntarily leaving it for the dry land.

The Cetaceous Fishes, or *Belluæ Marinæ*, form his first section, and are immediately followed by the Cartilaginous Fishes, called *Σελάχη* by Aristotle. Of the Cetaceans he says, that they breathe, like quadrupeds, by means of lungs, copulate, bring forth their young alive, and nourish them with their milk, and in the structure and use of all their internal parts agree with those animals.

The following are the genera enumerated by Ray:—

Balæna (2 species); *Cete* (1); *Orca* (2, but one not clearly defined); *Albus; Monoceros; Delphinus; Phocæna*. And he divides the *Cetacei generis Pisces, seu Balænæ*, into two great groups—the Toothed and Toothless; the latter having horny laminæ in the upper jaw.

The Toothed Whales are subdivided into those which have teeth in both jaws, and those which have teeth in the lower jaw; and there are further subdivisions depending on the absence or presence of the back-fin and the shape of the teeth.

The Toothless or Whalebone Whales are subdivided also with reference to the absence or presence of the back-fin, the presence of a blow-hole, or the employment of nostrils in respiration, the presence of plaits on the belly, and the width of the lower jaw.

Linnæus, in his last edition of the 'Systema Naturæ' (1766), defines the fulcra, or props, of his *Mammalia* to be 4 feet, with the exception of those Mammals which are merely aquatic, "in quibus pedes posteriores in caudâ pinnam compedes;" in other words, in which the posterior limbs are manacled or conjoined, so as to form a tail-fin.

The seven orders of *Mammalia* in this system are divided into three sections:—1, *Unguiculata;* 2, *Ungulata;* 3, *Mutica*. The seventh and last order, *Cete*, is the only one belonging to the section *Mutica*.

The following is the Linnæan definition of the last-named order:—

Pectoral fins in lieu of feet, and feet conjoined into a horizontal flattened fin in lieu of a tail. No claws. Teeth cartilaginous. Nose often a frontal pipe. Food, mollusks, fishes. Locality, the ocean.

Linnæus then declares that he has separated these Cetaceans from the Fishes, and associated them with the Mammals, on account of their warm bilocular heart, their lungs, their moveable eyelids, their hollow ears, "penem intrantem feminam mammis lactantem," and this, to use his own expressive words, "ex lege naturæ jure meritoque."

Here then we find the decisive step taken, with the unflinching firmness of a master mind, relying upon the philosophical principles that demanded the separation, and no longer yielding to popular prejudice by calling that a fish which he knew to be a mammiferous animal. Some parts of his definition—not much of it—may be open to criticism, as where he designates the teeth as cartilaginous, a term probably used to comprehend both the horny laminæ of the Whalebone Whales and the true teeth of the other Cetaceans; but the broad line of distinction is unassailable, and will ever remain so.

The order *Cete* is thus summarily defined by its great founder:—

Spiracles upon the head. Pectoral fins and horizontal caudal fin without claws.

Genera:—*Monodon, Balæna, Physeter, Delphinus.*

This, the last order of the Linnæan *Mammalia*, is immediately preceded by the *Belluæ*.

For Lacépède's arrangement, see his 'Histoire Naturelle, &c. Des Cétacés,' 4to., Paris, 1804.

The Cétacés form Cuvier's ninth and last order of Mammifères, the Ruminants (*Pecora*, Linn.) being the eighth.

Cuvier defines the Cetaceans to be mammiferous animals without posterior feet. Their trunk, he states, continues itself with a thick tail, which a cartilaginous horizontal fin terminates; and their head is joined to the trunk by a neck so short and thick that no narrowing or constriction of the part is perceptible, and composed of cervical vertebræ, which are very delicate, and in part conjoined or soldered together. Their anterior extremities have the first bones shortened, and the succeeding bones flattened and enveloped in a tendinous membrane, which reduces them to true fins. This gives nearly entirely the external form of the fishes, except that these last have the tail-fin vertical. The Cetaceans therefore remain constantly in the water; but as they respire by means of lungs, they are obliged to come frequently to the surface for air. Their warm blood—their ears open externally, although with very small apertures—their viviparous generation, the teats by means of which they suckle their young, and all the details of their anatomy, sufficiently distinguish them, Cuvier observes, from the fishes.

The same great zoologist remarks that their brain is large, and its hemispheres well developed; the petrous bone, or that portion of the cranium which contains the internal ear, is separated from the rest of the head, and only adheres thereto by ligaments. There is no external ear, nor are there any hairs upon their bodies. The form of their tail obliges them to move it from above downwards for their progressive motion, and aids them greatly in raising themselves in the water.

To the genera which up to Cuvier's time naturalists had reckoned among the *Cetacea*, he adds those which had formerly been confounded with the Walruses, and which form his first family, namely,—

The Herbivorous Cetaceans.

The teeth of these have a flat crown, which, Cuvier remarks, determines their mode of life, leading them often to leave the water to creep and feed on the bank: these have two teats on the breast, and hairy moustaches; two circumstances, he observes, which when they have been seen from a distance, with their heads raised vertically out of the water, have given them some resemblance to women or men, and have probably given origin to the stories of some travellers who pretend that they have seen Tritons and Syrens. Although in the cranium the bony nostrils open upwards, they are only pierced in the skin at the end of the muzzle. Their stomach is divided into four pouches, two of which are lateral; and they have a great cæcum.

Cuvier divides the Herbivorous *Cetacea* into—

1st, The Lamantins, or rather Manatees (*Manatus*, Cuv.); 2nd, the Dugongs, Lacép. (*Halicore*, Ill.); 3rd, the Stellères, Cuv. (*Rytina*, Ill.).

Cuvier's second family of this order consists of—

The Ordinary Cetaceans.

These are distinguished from the preceding by the singular apparatus which has procured for them the French name of Souffleurs, or Blowers. As they take, together with their prey, says Cuvier, large volumes of water into their very spacious mouth, there was a necessity for some outlet to get rid of it; it passes across the nostrils by means of a particular disposition of the velum palati, and is collected in a sac placed at the external orifice of the cavity of the nose, whence it is driven out with violence by the compression of powerful muscles by a narrow aperture pierced at the top of the head. Thus it is, adds Cuvier, that they produce those jets d'eau which cause them to be seen from afar by voyagers.

He further observes that their nostrils, incessantly traversed by floods of salt water, could not be lined with a membrane sufficiently delicate for the perception of odours. The whales therefore are without those projecting laminæ which are to be found in other animals; the olfactory nerve is wanting in many, and if any of them enjoy the sense of smelling they must have it very much obliterated. Their larynx, of pyramidal form, penetrates into the back nostrils for the reception of the air, and for the purpose of conducting it to the lungs, without any necessity on the part of the animal to lift its head and mouth out of the water: there are no projecting laminæ in their glottis, and their voice must be reduced to simple bellowings. They have no vestige of hair, but their body is covered with a smooth skin, under which lies the thick blubber abounding in oil, and the principal object for which they are sought. Their teats are near the anus, and they are unable to seize anything with their fins. Their stomach has five, and sometimes as many as seven, distinct pouches. In lieu of a single spleen they have many small and globular ones; those which have teeth have them conical, and similar to each other. They do not masticate their food, but swallow it rapidly. Two small bones, suspended in the flesh near the anus, are the only vestiges of posterior extremities. Many have on the back a vertical fin of a tendinous substance, but not sustained by bone. Their flattened eyes have a thick and solid sclerotic; their tongue has only smooth and soft integuments.

Cuvier divides this group into two small tribes: 1, those whose head bears the ordinary proportion to the body; and 2, those which have the head disproportionately great.

1st Tribe.

Genera:—1. *Delphinus*, Linn., with the sub-genera *Delphinus*, Cuv.; *Phocæna*, Cuv.; *Delphinapterus*, Lacép.; and *Hyperoodon*, Lacép.

2. *Monodon*, Linn.

2nd Tribe.

These Cetaceans have the head so large, that it is either a third or one-half of the length of the body; but neither the cranium nor the brain participates in this disproportion, which is entirely due to an enormous development of the bones of the face.

Genera:—1. *Physeter*, Linn. (the true Cachalots); with the sub-genus *Physeter*, Lacép. (Cachalots with a dorsal fin).

2. *Balæna*, Linn. (Whalebone Whales); with the sub-genera containing the *Balænopteræ* of Lacépède: namely, the *Balænopteræ* with a smooth belly; and the *Balænopteræ* with a plaited belly, commonly termed Rorquals. ('Règne Animal.')

The following synopsis of the families of *Cetacea* is taken from the 'Catalogue of the British Museum,' by Dr. J. E. Gray.

Sub-Order CETE.

Skin smooth, bald. Teats 2, inguinal. Limbs clawless. Fore-limbs fin-shaped; hinder united, forming a forked horizontal tail. Nostrils enlarged into blowers. Carnivorous.

Family 1st. BALÆNIDÆ.

Nostrils 2, separate, longitudinal. Palate with baleen. Jaw toothless. Head very large.

Genus I. *Balæna*.
Species 1. *B. mysticetus*, Right Whale.
2. *B. marginata*, Western Australian Whale.
3. *B. australis*, Cape Whale.
4. *B. Japonica*, Japan Whale.
5. *B. antarctica*, New Zealand Whale.
6. *B. gibbosa*, Scrag-Whale.
Genus II. *Megaptera*, Humpbacked Whales.
Species 7. *M. longimana*, Johnston's Hump-Backed Whale.
8. *M. Americana*, Bermuda Hump-Back.
9. *M. Poeskop*, Cape Hump-Back.
10. *M. Kuzira*, the Kuzira.
Genus III. *Balænoptera*.
Species 11. *B. rostrata*, Pike-Whale.
Genus IV. *Physalus*.
Species 12. *P. Antiquorum*, Razor-Back.
13. *P. Boops*.
14. *P. Sibbaldii*.
15. *P. fasciatus*, Peruvian Finner.
16. *P. Iwasi*, Japan Finner.
17. *P. antarcticus*.
18. *P. Brasiliensis*.
19. *P. australis*, Southern Finner.

Family 2nd. CATODONTIDÆ, or PHYSETERIDÆ.

Nostrils 2, separate, longitudinal. Palate smooth. Lower jaw toothed. Head very large.

Genus I. *Catodon*, Spermaceti Whales.
Species 20. *C. macrocephalus*, Northern Sperm-Whale.
21. *C. Colüeti*, Mexican Sperm-Whale.
22. *C. polycyphus*, South Sea Sperm-Whale.
Genus II. *Kogia*, Short-Headed Whales.
Species 23. *K. breviceps*, Short-Headed Whale.
Genus III. *Physeter*.
Species 24. *P. Tursio*, the Black Fish.

Family 3rd. DELPHINIDÆ (DOLPHINS).

Nostrils united, lunate, transverse. Palate smooth. Jaws toothed, rarely deciduous. Head moderate.

Genus I. *Hyperoodon*.
Species 25. *H. Butzkopf*, Bottle-Head.
26. *H. rostratum*, Beaked Hyperoodon.
27. *H. Doumetii*, Corsican Hyperoodon.
28. *H. Desmarestii*, Desmarest's Hyperoodon.
29. *H. latifrons*.
Genus II. *Ziphius*.
Species 30. *Z. Sowerbiensis*.
31. *Z. Sechellensis*, Sechelle Ziphius.
Genus III. *Delphinorhynchus*.
Species 32. *D. micropterus*, Blainville's Whale.
Genus IV. *Monodon*.
Species 33. *M. monoceros*, the Narwhal.
Genus V. *Beluga*.
Species 34. *B. Catodon*, Northern Beluga.
35. *B. Kingii*, Australian Beluga.
Genus VI. *Neomeris*.
Species 36. *N. Phocænoides*, Neomeris.
Genus VII. *Phocæna*.
Species 37. *P. communis*, Common Porpoise.
Genus VIII. *Grampus*.
Species 38. *G. Cuvieri*, Cuvier's Grampus.
39. *G. Rissoanus*, Risso's Grampus.
40. *G. Richardsonii*.
41. *G. Sakamata*.
Genus IX. *Globiocephalus*.
Species 42. *G. Svineval*, Pilot-Whale.
43. *G. intermedius*, the Black Fish.
44. *G. affinis*, Smaller Pilot-Whale.
45. *G. Sieboldii*, Naiso Gota.
46. *G. macrorhynchus*, South-Sea Black Fish.
Genus X. *Orca*.
Species 47. *O. gladiator*, Killer.
48. *O. crassidens*, Lincolnshire Killer.
49. *O. Capensis*, Cape Killer.
50. *O. intermedia*, Small Killer.
Genus XI. *Lagenorhynchus*.
Species 51. *L. leucopleurus*, White-Sided Bottlenose.
52. *L. albirostris*, White-Beaked Bottlenose.
53. *L. Electra*, the Electra.
54. *L. cæruleo albus*.
55. *L. Asia*, the Asia.
56. *L. acutus*, Eschricht's Dolphin.
57. *L. clanculus*.
58. *L. Thicolea*.

Genus XII. *Delphinapterus.*
Species 59. *D. Peronii*, Peron's Dolphin.
60. *D. borealis.*
Genus XIII. *Delphinus.*
Species 61. *D. Heavisidii*, Hastated Dolphin.
62. *D. obscurus*, Dusky Dolphin.
63. *D. compressicauda*, Compressed-Tailed Dolphin.
64. *D. Tursio*, Bottlenose Dolphin.
65. *D. Abusalam*, the Abusalam.
66. *D. Eutropia*, the Eutropia.
67. *D. Eurynome*, the Eurynome.
68. *D. Metis*, the Metis.
69. *D. Cymodoce*, the Cymodoce.
70. *D. Doris*, the Doris.
71. *D. frenatus*, Bridled Dolphin.
72. *D. Clymene.*
73. *D. Styx*, the Styx.
74. *D. Euphrosyne*, the Euphrosyne.
75. *D. Alope*, the Alope.
76. *D. microbrachium.*
77. *D. dubius.*
78. *D. loriger.*
79. *D. Delphis*, the Dolphin.
80. *D. Janira*, the Janira.
81. *D. Novæ Zealandiæ*, New Zealand Dolphin.
82. *D. Forsteri*, Forster's Dolphin.
83. *D. Sao*, the Sao.
84. *D. longirostris*, Cape Dolphin.
85. *D. microps*, Small-Headed Dolphin.
Genus XIV. *Steno.*
Species 86. *S. Malayanus*, Malay Dolphin.
87. *S. frontatus*, Fronted Dolphin.
88. *S. compressus*, Narrow-Beaked Dolphin.
89. *S. attenuatus*, Slender-Beaked Dolphin.
90. *S. fuscus*, Cuban Steno.
91. *S. rostratus*, Beaked Dolphin.
Genus XV. *Pontoporia.*
Species 92. *P. Blainvillii*, the Pontoporia.
Genus XVI. *Inia.*
Species 93. *I. Geoffroyii*, the Inia.
Genus XVII. *Platanista.*
Species 94. *P. Gangetica*, the Sou Sou.

Sub-Order SIRENIA.

Skin rather hairy. Whiskers rigid. Limbs clawed. Teats 2, pectoral. Nostrils 2, apical. Herbivorous.

Family MANATIDÆ.

Grinders none, or flat crowned. Front of jaws covered with horn.
Genus XVIII. *Manatus.*
Species 95. *M. australis*, the Manatee.
96. *M. Senegalensis*, the Lamantin.
Genus XIX. *Halicore.*
Species 97. *H. Dugong*, Indian Dugong.
98. *H. Tabernaculi.*
99. *H. australis.*
Genus XX. *Rytina.*
Species 100. *R. gigas*, Morskaia Korova.

The following is M. F. Cuvier's arrangement of the *Cetacea*, to which, and that of Baron Cuvier, we shall principally refer when speaking of the anatomy of these creatures.

Tribe 1.

PHYTOPHAGA (Vegetable-feeding).

Teeth of different kinds; molars with flattened crowns, corresponding to the vegetable nature of their food. Mammæ two, pectoral. Lips provided with stiff bristles. External nostrils always two, situated at the extremity or upper part of the rostrum, which is obtuse.

Genera: ***Manatus***, Cuv.; ***Halicore***, Cuv.; ***Rytina***, Ill.

Tribe 2.

ZOOPHAGA (Animal-feeding).

Teeth of one kind or wanting, not adapted for mastication. Mammæ two, pudendal. External nostrils double or single, situated on the top of the head.

A. With the head of moderate size.

Family *Delphinidæ.*

Teeth in both jaws, all of simple structure, and, generally, conical form. No cæcum.

Genera: *Delphinorhynchus; Delphinus; Inia; Phocæna.*

M. F. Cuvier is of opinion that the following genera seem to form the types of as many distinct families of Zoophagous Cetaceans.

Genera: ***Monodon; Hyperoodon; Platanista.***

B. With the head of immoderate size, equalling one-third the length of the body.

Family 1. *Catodontidæ.*

Teeth numerous, conical, but developed only in the lower jaw. External nostrils or blow-holes confluent. No cæcum.

Genera: *Catodon; Physeter.*

Family 2. *Balænidæ.*

No teeth; their place supplied by the plates of baleen, or whalebone, attached to the upper jaw. Blow-holes distinct. A cæcum.

Genera: *Balænoptera; Balæna.* ('Histoire Naturelle des Cétacés,' &c.)

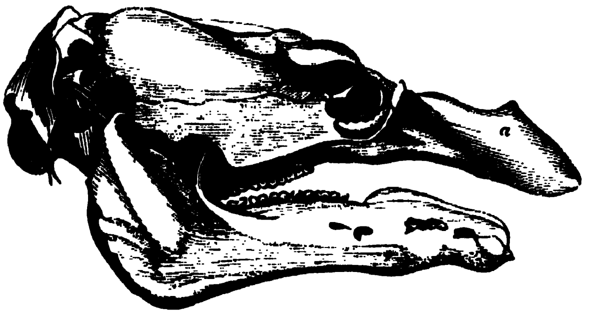
On the arrangement and remarks of the two Cuviers, Dr. J. E. Gray makes the following criticism. After referring to Lacépède's classification, he says:—

"Cuvier, dissatisfied with this state of things, in his 'Ossemens Fossiles' examined the various documents and consulted the authorities which had been used by Lacépède; but he appears to have undertaken the work with a predisposition to reduce the number of species which his predecessor had described to the smallest number. Thus, he concludes that there are only eleven species of Dolphins, one Narwhal, one Hyperoodon, one Cachalot or Sperm-Whale; and he appears to think there are only two Whalebone Whales—the Right Whale and the Finner. To make this reduction: First, he believes that the Hump-Backed Whale of Dudley is only a whale that has lost its fin, not recognising that the Cape Rorqual, which he afterwards described from the fine skeleton now shown in the inner court of the Paris Museum is one of this kind. Secondly, that the Black Fish and the Sperm-Whale are the same species, an error which must have arisen from his not having observed that Sibbald had figured the former, for he accuses Sibbald of twice describing the Sperm-Whale; and when he came to Schreiber's copy of Sibbald's figure, he thinks the figure represents a dolphin which had lost its upper teeth, overlooking the peculiar form and posterior position of the dorsal fin, and the shape of the head, which is unlike that of any known dolphin. This mistake is important, as it vitiates the greater part of Cuvier's criticism on the writings of Sibbald, Artedi, and others, on these animals. Unfortunately these views have been very generally adopted without re-examination. But in making these remarks, it is not with the least desire to underrate the great obligation we owe to Cuvier for the papers above referred to; for it is to him that we are indebted for having placed the examination of the whales on its right footing, and for directing our inquiries into the only safe course on these animals which only fall in our way at distant periods, and generally under very disadvantageous circumstances for accurate examination and study.

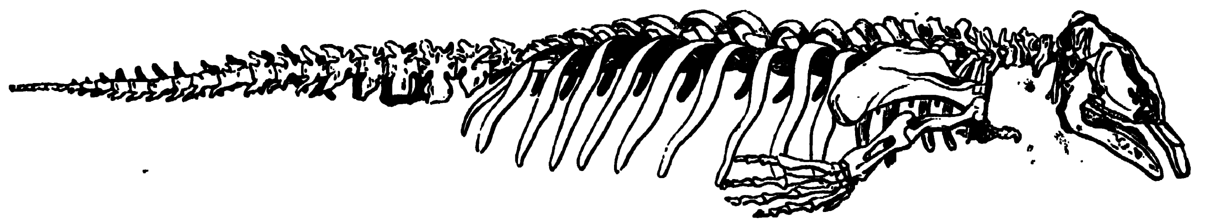
"M. F. Cuvier's 'Cetacea' (Paris, 1836) is little more than an expansion of his brother's essays, with a compiled account of the species; but he has consulted with greater attention the works of Sibbald and Dudley; has some doubts about the finned Cachalots being the same as the Sperm-Whale (p. 475), but at length gives up the subject. He has found that the Hump-Backed Whale is evidently a Rorqual (p. 305), but does not record it as a species, nor recognise it as the Cape Rorqual, nor as Dr. Johnston's Whale: the latter he incorrectly considers the same as *B. Physalus.* He combines together as one species Quoy's Short-Finned Rorqual of the Falkland Islands, with Lalande's Long-Finned Whale of the Cape (p. 352). He is in great doubt about the hump of the Cachalots (p. 279): his remarks on that subject, and on the Cachalots of Sibbald, show how dangerous it is for a naturalist to speculate beyond the facts before him."

Before giving any account of the natural history of the species of Whales, we shall make some remarks on their general structure and organisation. First we shall speak of the structure of the skeleton in the

Phytophagous Cetaceans—of which the Lamantin, or Manatee, is an example. The nasal bones in the skull of the Manatee are very small, almond-shaped, separated from each other, and let in on each side in a notch of the frontal bone. The result of this conformation is a very large aperture of the bony nostrils. The rest of the bones of the nose are nevertheless replaced by cartilages, so that in the living animal the opening of the nostrils is, as ordinarily, at the end of the muzzle. The intermaxillary bones carry no teeth in the adult, nor at any period of life, except during the first days of embryonic existence; they are notwithstanding very much extended longitudinally, and they re-ascend along the edge of the nostrils to above the region of the eye. The orbits are very much advanced and very projecting. The suborbital hole is pierced in the re-entering angle formed by the projecting frame of the orbit with the anterior part of the maxillary bone, so that it is not perceptible when the cranium is seen in profile. This projection of the orbit causes the distance between the lower external border of the zygomatic portion of the intermaxillary bone and the teeth to be greater than the width of the palate. The frontal bones, whose anterior branches are much separated, in order that they may embrace the aperture of the nostrils and form the walls of the orbits, give off each an obtuse postorbital apophysis. The cheek-bone extends throughout the lower half of the orbit on the orbital apophysis of the maxillary bone, and thus borders the whole of the orbit anteriorly; it gives off a postorbital inferior apophysis. A very small lachrymal bone is let in at the anterior angle between the frontal, the jugal, and the maxillary, which intervenes at this point between the lachrymal and the jugal bones. A little lower down, in a depression, is pierced the large suborbital hole, which is thus carried farther backward than the edge of the orbit, and cannot give place to any canal. The dental part of the maxillary is more inward than the orbit, so that the interior part of the wall of this cavity is formed by a flat advancement of that bone. The zygomatic apophysis of the temporal bone is thicker than in any other animal, but the rest of the bone is moderate; it contributes to form the sides of the occipital crest, and leaves above, between it and the superior and lateral occipitals, a space which permits the petrous bone to be seen. The two crests which limit the temporal fossa above run in a nearly parallel direction, and do not unite in a single line, as in the greater part of the *Carnivora*. In the adult there is only a single unequal parietal bone, which enters largely into the temple; but in the fœtus there are two, completely separated by a double interparietal; these four bones however speedily unite, not only with each other, but, what is singular, with the upper occipital, even before the other parts of the occipital are united. The plane of the occipital is inclined from before backwards, and from above downwards, and the occipital crest makes an obtuse angle; there is no vestige of a mastoid apophysis. Below, the intermaxillaries form the point of the muzzle, occupying nearly the fourth of the palate, and surrounding a large incisive hole, which is single, because they have no internal apophysis. Very young Manatees have a small tooth in each of their intermaxillaries, thus completing, Cuvier observes, their analogy with the Dugongs. He observed this in the fœtus, but he remarks that the tooth disappears at a very early period. The jaws commence a little behind the suborbital hole, which, from the disposition of the orbits, is found nearly at their level. The palatine bones advance in a narrow and obtuse point, occupying nearly a fourth of the palate, and contribute to the formation of two large pterygoid wings, whose body is in other respects almost entirely sphenoidal, and does not separate itself from the body of the posterior sphenoid even in the fœtus. The temporal alæ of the sphenoid remain distinct much longer. The palatine bone shows itself in the temple by a narrow tongue-shaped process, between the maxillary on one side and the anterior sphenoid and the frontal on the other; but its continuity is partially hidden by the dental portion of the maxillary bone, which is continued backwards to the wing of the sphenoid, which it touches without articulation. The anterior sphenoid also only shows itself in the temple by a narrow tongue-shaped process, but much shorter than that of the palatine. It does not reach the parietal bone, and the orbital wing of the sphenoid touches the frontal. The body of the basilary bone and that of the two sphenoids are conjoined with each other and with the cribriform plate of the ethmoidal bone, considerably before the basilary unites with the lateral occipitals. The area of the section of the cranium is nearly half of that of the face; it is singularly high, especially before, in proportion to its length. The frontal bones are there nearly vertical; the cribriform plates are found below the anterior surface; they are small, not much pierced with holes, and scarcely sunk. The crista galli is prolonged more backwards than they are. There is no sella; the whole base is united; the median fossæ hardly depressed. The analogous hole of the spheno-palatine is large, and entirely in the palatine bone. The optical foramen is small and in the form of a canal; the spheno-orbital, which comprises also the rotundum, is rather large and of an oval form; the foramen ovale is a notch of the border of the posterior sphenoid, completed by the tympanic bone; the condyloidean is very small, and in the form of a notch of the lateral occipital. The articulation of the lower jaw is formed by nearly flat sufaces, as in all the *Herbivora*. The ascending ramus is very wide, and its posterior angle rounded. The coronoid apophysis is directed forwards, and truncated nearly into a hatchet-shape. The region of the symphysis is thick and elongated anteriorly. The whole portion that supports the gum is perforated with small holes. The holes for the exit of the lower maxillary are very large. The lateral and dental portions of the lower jaw are very large and rounded.



Skull of Manatee (*Manatus australis*).

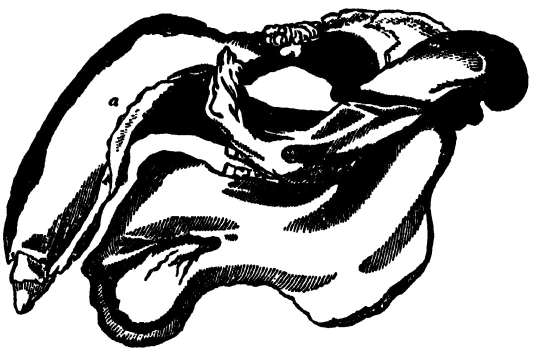


Skeleton of Manatee (*Manatus australis*).

The shoulder-blade is nearly semi-elliptical; its lower line being almost straight, and answering to the great axis of the ellipse: the spine occupies only the anterior half of the bone. Its greatest projection is near its root; it is prolonged forwards into a pointed acromion, which ascends a little obliquely, and which has the air of terminating by an articular facet. There are no clavicles. A strong blunt tubercle occupies the place of the coracoid process. The humeral surface is a little higher than it is wide, and very concave. The upper part of the humerus is also very convex; its external tuberosity is very projecting. The bicipital groove is not deep, but there remains a deep canal between the internal tuberosity and the articular head; the deltoidean crest is but little marked. The lower head is a rather oblique simple pulley, ascending at the internal edge. Its width is not greater than its antero-posterior diameter. The internal condyle projects much more than the other backwards. The ulna and radius, which are rather short in proportion to their stoutness, and still more so with reference to the size of the animal, are joined together by their two extremities. Their upper articulation corresponds to the pulley of the humerus; the head of the radius is wider than it is high, and, even when not conjoined, is incapable of executing rotation; in which circumstance the Manatee differs still more widely from the Seals, to approximate itself to the *Herbivora*. The radius has below, at its external surface, two pointed crests. There are only six carpal bones; the pisiform bone is wanting, and the trapezium and trapezoid are united into a single bone, which is articulated at once with the metacarpal bone of the thumb and of the fore finger. The analogue of the os magnum responds to those of the fore and middle fingers. The unciform bone responds to the middle, ring, and little fingers, which last articulates itself at the same time with the cuneiform bone of the first row. Each of those bones has also in the Manatee its particular character. The pisiform bone, Cuvier observes, is also wanting in the Dolphins, and is very small in the Seals and Sloths, whilst it is very long in the animals which make much use of their fore feet for seizing or progression. The metacarpal bones are flat above and carinated below; that of the thumb, which has no phalanges to support, terminates in a point; the others are enlarged at their lower extremity. That of the little finger is longer and the most enlarged of all. The ring-finger, on the contrary, is that which has the longest phalanges; but those of the little finger are flatter and wider. All the articular surfaces of the phalanges are rather full, and must possess but little mobility.

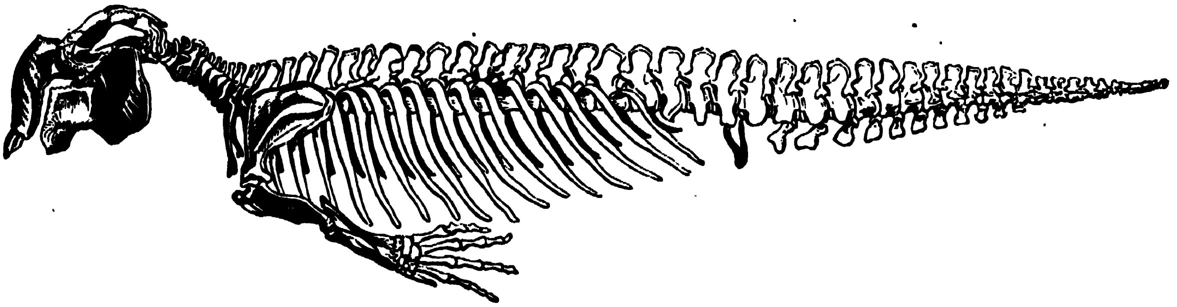
There are only 6 cervical vertebræ, all very short. The annular portion of the third, the fourth, and the fifth is incomplete. The transverse apophyses of the fourth, fifth, and sixth are pierced with a hole; they are all simple. There are 16 ribs and 16 dorsal vertebræ; the spinous apophyses of which last are moderately elevated and inclined backwards. Counting from the sixth dorsal, there is on the ventral surface of their body a small sharp crest. The two succeeding vertebræ may be called lumbar, and then there would be 22 caudal. Thus there are in all 46 vertebræ. Under the joint of the first eleven caudal vertebræ are articulated small chevron bones, as in the greater part of quadrupeds which have a powerful tail. The transverse apophyses of the vertebræ of the tail are very large, especially in the first, but the spinous processes are inconsiderable; which accords, Cuvier remarks, with the depressed form of the tail-fin, to prove that the Manatee swims by a vertical movement of the tail. The ribs are singularly stout and thick; their two edges are rounded, and they are as convex internally as externally.

The connections of the bones of the skull of the Dugong, &c. are, Cuvier observes, nearly the same as in the Manatee. To change, he adds, the head of the latter to that of the Dugong, it would suffice to render more convex and elongate the intermaxillary bones to make room for the tusks, and to curve the symphysis of the lower jaw downwards so as to make it conform to the inflection of the upper jaw. The muzzle would then assume the form that it has in the Dugong, and the nostrils would be raised as they are in that animal. In a word, says Cuvier, one might say that a Manatee is only a Dugong whose tusks are not developed.



Skull of Dugong (*Halicore Dugong*).

The enormous development of the intermaxillary bones of the Dugong carries up the aperture of the bony nostrils much higher than in the Manatee, and it is situated at the superior part of the head in the middle of its length and directed upwards, its form being a large oval as in the Manatee of Senegal. The whole skull, and particularly the frontal bones, are for the same reason much shorter in proportion than in the Manatee. The branches of the frontal bone which form the upper part of the orbit are more delicate and more rugose. The maxillary portion which serves as a floor for the orbit is narrower; the jugal bone in turning to form the anterior and inferior edge of the orbit is more compressed and directed more downwards. There is also a lachrymal bone in the anterior angle more considerable than in the Manatee, but equally without any hole. The zygomatic apophysis of the temporal bone is more delicate and more compressed. The connections of the bones of the cranium are the same, but at the inferior surface the basilary bone is united with the lateral occipitals rather than with the posterior sphenoid. A very great solution of continuity is seen in the bottom of the orbit and of the temple, and establishes in the skeleton an extensive communication between these two fossæ and that of the nostrils; it is intercepted between the maxillary, the frontal, the anterior sphenoid, and the palatine bones. The continuity of the temporal portion of the palatine with the rest of the bone is not here concealed, as in the Manatee, by a production of the maxillary bone. The occiput is narrower and its crest less marked than in the Manatee; the frame of the tympanum is also narrower and more delicate, but the bone of the ear is disposed nearly in the same way, and is let in between the same bones. There also remains in the skeleton a large empty space between that bone, the basilary, and the anterior sphenoid. Within the cranium there is no bony tentorium; the cribriform fossa is reduced to two simple depressions very much separated from each other, and which terminate anteriorly by two or three small holes. There is no sella Turcica. The optic aperture is a long narrow canal. The lower jaw is of a height corresponding with the curvature and length of the intermaxillary bones. This part shows in the adult the remains of three or four alveoli on each side.



Skeleton of Dugong (*Halicore Dugong*).

The atlas is very similar to that of the Manatee; the axis the same. The five other cervical vertebræ are very delicate, but not conjoined. There are 18 dorsal vertebræ, the spinous apophyses of which are arranged nearly in a straight line. Counting from the ninth, the ribs do not attach their head between two vertebræ, but only to the same vertebra, to the transverse apophysis of which they are articulated. The ribs are not nearly so stout as in the Manatee, but, notwithstanding, the first are still very thick and have their edges blunt. After the 18 dorsal vertebræ come 27, and perhaps more, whose spinous apophyses diminish progressively. In the lumbar vertebræ the transverse apophyses are very long; afterwards they diminish by degrees on the sides of the tail, and again become rather longer at its extremity, apparently for the support of the tail-fin. It would seem that the first three only belong to the loins. The fourth has towards its extremity a facet, which is probably destined for the attachment of the pelvic bones, which last are well marked in the Dugong. They are two long slender bones, which have some resemblance in form to the clavicles of man. There are V-shaped bones articulated under the interval of the vertebræ after that which comes beyond the pelvis. They diminish by degrees, and seem to terminate altogether under the last fourth of the tail.

The shoulder-blade, as in the Manatee, has its anterior angle rounded, the posterior angle sharp, and carried well backwards; the posterior border very oblique and slightly concave. Its spine is projecting, its acromion pointed, but much less elongated than in the Manatee. The coracoid process is much more pointed than in that animal, and directed forwards and a little inwards. The humerus is much stouter and shorter than in the Manatee; its deltoid crest projects more, and it forms with the great tuberosity a rhomboidal protuberance. The bones of the fore-arm are rather longer in proportion than those of the Manatee, but their form is the same, and they are equally conjoined at their two extremities. There are only four carpal bones; two of which are in the first row, one for the radius, the other for the ulna; and two in the second, the first of which supports the metacarpals of the thumb and fore finger, and the second those of the middle and ring-finger. That of the little finger bears upon the second bone of the second row, and upon that of the first. The thumb, as in the Manatee, is reduced to a pointed metacarpal. The other fingers have the ordinary number of phalanges, the last of which are compressed and obtuse. ('Ossemens Fossiles.')

Professor Owen, in his 'Anatomy of the Dugong' ('Zool. Proc.,' 1838), remarks that after the excellent and elaborate descriptions of the osteology of that animal by Cuvier, Rüppell, and others, but little remains to be said on the subject. The bones, Professor Owen observes, are chiefly remarkable, as in the Manatee, for their dense texture and the non-development of medullary cavities in them. This reptile-like condition of the skeleton is, he adds, further exemplified in the loose connection of the bones of the head. The bones are not loaded with oil as in the true *Cetacea*. All the specimens examined by the Professor presented 7 cervical and 19 costal vertebræ, corresponding to the 19 pairs of ribs; but the number of the remaining vertebræ exceeded that ascribed to the Dugong by Home and Cuvier, there being at least 30, making in all 55. Rüppell assigns to the *Halicore tabernaculi* 7 cervical, 19 dorsal, 3 lumbar, 3 pelvic, and 27 caudal vertebræ; in all 59. Professor Owen found, as Rüppell also describes, that the first four pairs of ribs reached the sternum through the medium of cartilages; all the others terminated freely in the mass of abdominal muscles: the tenth to the fifteenth Professor Owen found the longest, and the last the shortest.

The Professor points out that the affinity of the Dugong to the *Pachydermata* is here again illustrated by the great number of the ribs. The lower jaw is, he observes, articulated to the cranium by a true synovial capsule, reflected over cartilaginous surfaces, and not, as in the Carnivorous *Cetacea*, by a coarse and oily ligamentous substance. In treating of the rudimental pelvic bones of the Dugong, he remarks that in the true *Cetacea* the parts analogous to the ischia are alone present, and that those bones serve a similar purpose in the Dugong.

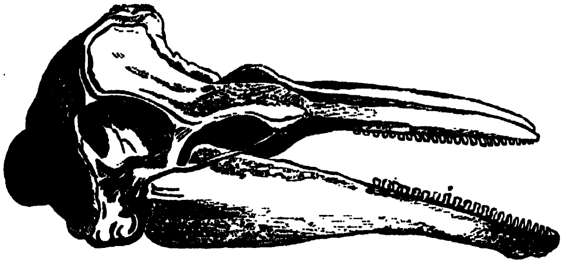
Zoophagous Cetaceans.—The skull in the Dolphins is very much elevated, very short and very convex behind. The occipital crest surrounds the top of the head, and descends on each side on the middle of the temporal crests, which are directed much more backward than it is. This large and occipital surface is formed by the occipital, the interparietal, and parietal bones, which early unite into one piece. The parietal bones descend on each side into the temple between the temporal and the frontal bones, and they there reach the posterior sphenoid bone. In front and above, the parietals terminate behind the occipital crest, and the maxillaries approaching on their side, what appears of the occipital bone externally only represents a very narrow band, which traverses the skull from right to left, and seems to dilate at each extremity to form the wall of each orbit; but on raising the maxillary and nearly the whole of the anterior surface of the cranium, the frontal bone will show itself much larger than it appears to be externally. The nasal bones are two rounded tubercles let into two fossæ of the middle of the frontal, and in front of which the nostrils are sunk vertically. The posterior and vertical surface of these nostrils is formed by the cribriform plate of the ethmoid bone, but it has very few holes—three or four, sometimes less. The rest of the internal contour of the nostrils belongs to the maxillaries. Their septum is the vomer, which is united to the ethmoid bone as ordinarily. The maxillaries, after forming the long muzzle, and arriving in the neighbourhood of the orbits, enlarge, and cover with a wide and dilated band the ceiling which the frontal bone gives to those cavities, and the whole anterior surface of the frontal bone, with the exception of the small band, which they suffer to appear along the occipital crest. They also touch the bones of the nose. The two intermaxillaries form the external and anterior border of the nasal aperture, and descend upon and between the two maxillaries up to the point of the muzzle, where they even show themselves below; but the maxillaries are seen a little between them, above, near the nostrils.

But the frontal bone does not entirely form the lower surface of the ceiling of the orbit; the anterior part is formed by a flat and irregular bone, covered above, like the frontal, by the maxillary; this, which is the jugal bone, gives off from its anterior angle a slender and long apophysis, which is directed backwards, and proceeds to articulate itself to the zygomatic apophysis of the temporal bone: this delicate filament is the sole bony limit of the orbit below. The zygomatic apophysis of the temporal bone unites itself to the postorbital apophysis of the frontal, in order to limit the orbit backwards; whence it happens that the whole zygomatic arch properly so called appertains to the temporal bone, which last extends but little into the temple, and terminates at the temporal crest, so that it does not appear in the occiput. Below, the lateral occipital and the basilary bones produce projecting plates, which, uniting to the continuation of the pterygoidean ala and to a lamina of the temporal bone, compose a sort of vault, under which are suspended by ligaments the petrous and tympanic bones, which are promptly conjoined into one piece. The parietal bone, after having passed behind the temporal, forms a part of this vault. The temporal bone itself therefore seems to be almost foreign to the composition of the cranium, only serving to stop some small holes remaining in the parietal. This, Cuvier observes, is the commencement of the separation which it undergoes in the inferior classes. The part of these crests which borders the basilary region on each side makes this region resemble a wide canal. At the bottom of the orbit are seen the two sphenoids placed as ordinarily—the posterior touching the temporal, the parietal, and the frontal; the anterior touching the posterior, the frontal, and the internal pterygoid apophysis: but the great peculiarity is the form of the back nostrils. The maxillaries being prolonged into a flattened muzzle, and the teeth terminating in front of the orbit, the maxillary is not on the floor nor on the anterior or lateral walls of that cavity, but at its ceiling, as is also the jugal bone: it completes the internal border of this ceiling. From the entire posterior contour of the lower surface or palatine of these maxillary bones rises a sort of quadrangular pyramid, whose base is traversed vertically by the nostrils, and in which the rest of the space is hollow, or contained between two laminæ open behind. These form a sort of double walls, which surround the posterior aperture of the nostrils. They are composed of the palatines and the pterygoid internal apophyses. Each palatine is folded back on itself in an irregular ring to form the base of this double wall, and the ceiling is completed by the maxillary to which it is articulated. The internal pterygoid apophysis is only recurved in the form of S. One of its curvatures articulates itself externally to the palatine to prolong the lower and external wall; the other unites to the other arch of the palatine, and afterwards continues on the anterior sphenoid to articulate itself to the vomer, and thus complete the internal part of this entourage of the back nostril; whence it results, that the entire border of the back nostril, except the vomer, belongs, as in the Ant-Eaters, to the internal pterygoid apophysis. The great sinus intercepted between the two walls of this border is a peculiarity in the Dolphin: this internal pterygoid always remains distinct. The posterior sphenoid is conjoined with the basilary much sooner than to the anterior sphenoid: Cuvier even found it conjoined in some fœtuses before any of the other bones. This nearly absolute derangement of the bones has, Cuvier observes, much changed the direction of the holes. In place of the incisive hole there is a long canal, which proceeds between the two maxillaries and the two intermaxillaries, from the end of the muzzle to the nostrils, near which it bifurcates. The suborbital hole is to be sought in the ceiling of the orbit, where it represents a cavity open below, from which proceed in different directio[illegible]anals which go to open on the superior surface of the maxillaries [illegible]ermaxillaries, not below but above and opposite to the orbit. [illegible] could find neither lachrymal bone nor hole. In a hollow in front of the orbit, between the maxillary, the vomer, and a point of the palatine bone, is a small hole which ascends in the nostril and represents the spheno-palatine. To respond to the pterygo-palatine, Cuvier could only perceive a small hole on the junction of the palatine to the maxillary in the palate, which enters the sinus placed on each side of the posterior nostrils. The optic hole is moderate and in the anterior sphenoid as ordinarily. The spheno-orbital hole between the two sphenoids also performs the office of the round hole. There is an oval hole in the posterior sphenoid, and more internally in the same bone a hole for a vessel. An aperture between the temporal, the lateral occipital, the basilary, and the posterior sphenoid gives passage to the nerves of the ear to go to the petrous bone. In front of it, and very near, is the carotidean hole. In the basilary bone, and in a notch of the borders of this vault of the ear, is the condyloidean hole, which is very small. It is the posterior border of this vault which occupies the place of the mastoid apophysis.

Internally the cerebral cavity is very remarkable, inasmuch as its height surpasses its length. The floor is very compact. The sella is but slightly marked. The cerebellar fossæ are the most hollowed; there is often a very projecting bony tentorium in its middle; the falx is always bony backwards, but it has no crest, and some small holes are scarcely perceptible in the cribriform plate. The petrous and tympanic bones are not joined to the cranium by any suture, and are not even inclosed, but only suspended by ligaments under the sort of vault above noticed. They unite at an early period into a single bone of the ear. The occipital condyles are large, but project little. The hole, directed entirely in the line of the head, is nearly circular.

Cuvier remarks that complete symmetry is never found in the skulls of Dolphins; the two nostrils, the two nasal bones, and the adjacent parts, never appeared to him equal, as in other mammiferous animals; and this, he observes, conducts us to the extreme inequality of those parts in the Cachalots.

The various species of Dolphins differ from each other in the relative length and width of the muzzle, the number of teeth, and the divers convexities or concavities of their parts, the palate, &c. Cuvier points out these variations in the species, and particularly notices the Dolphin of the Ganges (Susuk) as the most extraordinary in the structure of its cranium.

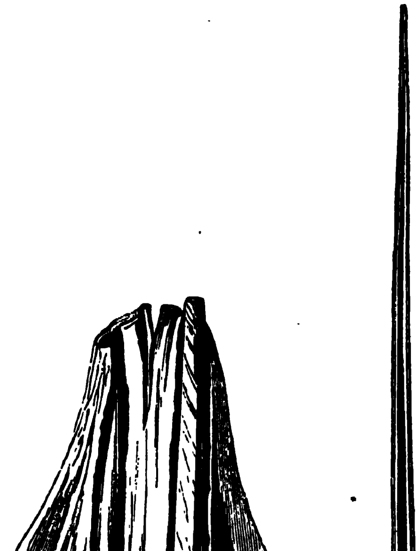


Skull of Porpesse.

In the common Dolphin the seven cervical vertebræ are united in a single body, and so they are in the Porpesse; but this is not universally the case, for in the Dolphin of the Ganges, for instance, the cervical vertebræ are as distinct as in any quadruped. But where they are anchylosed, as in the common Dolphin, the atlas is fully developed, and has sufficiently strong, transverse, conic apophyses. The body of the axis is very delicate; but its spinous apophysis, anchylosed to the atlas, is also well marked. The four succeeding vertebræ are, to use Cuvier's expression, as thin as paper, and their annular part unites above to the lower surface of the spine of the axis. The seventh cervical has some volume and rather strong distinct apophyses. The dorsal vertebræ are 13 in number, and there are 13 ribs. The first three ribs only have a head and a tubercle, and are articulated on the body of two vertebræ and on the extremity of the transverse apophysis of one of them. The ten succeeding ribs are only articulated to the extremity of the transverse apophysis. The last cervical and the first six dorsal have their articular apophyses united to each other by horizontal surfaces, the anterior of which is above. At the sixth they begin to become oblique; at the seventh they are nearly vertical. Commencing with the fourth, the transverse apophysis gives off a small point from its anterior border. This point approaches the anterior articular apophysis, and becomes blended with it at the seventh; afterwards these points form the only articular apophysis; those of one vertebra embracing the lower part of the spinous apophysis of the preceding vertebra. Towards the twenty-second vertebra or the second lumbar they no longer reach it; but they remain irregularly marked far upon [illegible] tail. The transverse apophyses of the lumbar region are ve[illegible] and the spinous very high. On the tail they are shortened; [illegible]nous are widened; and the transverse are directed rather for[illegible]. They disappear at the forty-ninth vertebra, and the spinous at [illegible] fifty-first or fifty-second. The V-shaped bones (hæmapophyses of Professor Owen) of the under part of the tail commence under the thirty-eighth. The body of the vertebræ are round, rather angular below; more compressed and thicker in the region of the back; shorter in the lumbar region and in that of the tail, where they present a kind of carination below. The anterior and posterior epiphyses remain a long time distinct. The sternum is composed of three bones; the first, very wide, is notched in front, and gives off on each side between the first and second rib a sharp point directed backwards. There is a hole in the middle. The second is simply rectangular. Between the first and it the second rib is articulated; the third rib is attached between the second and third bone, which receives on its sides the fourth, and towards its point the fifth and sixth, which is the last true rib. The sternal parts of the ribs are all ossified.

The shoulder-blade is fan-shaped, with the external surface slightly concave, and its spinal border forming the segment of a circle: the two other borders are slightly concave and nearly equal; the anterior is bifurcated, and thus presents two edges—one external, the other nearer the ribs. The external gives off a flat apophysis directed forwards, and enlarged at its extremity, which represents the acromion. The other border, which is the true anterior border, gives off also, but close to the articular surface, a flat apophysis, less than the acromion, descending a little and equally enlarged at the end: this is the coracoid process. The humerus is very short and stout. On the anterior part of its upper extremity or head is a tuberosity as large as itself: the lower head is enlarged and compressed from before backwards, and does not terminate in a facet that may be termed articular, but unites by synchondrosis with the radius and ulna: these two bones are short and compressed. The radius is in front and the largest, and its form is nearly rectangular: the ulna is behind and narrower. Its posterior border is concave, and it forms at its upper extremity a projecting angle, which is the only vestige of the olecranon. The carpal bones are flat, angular, and together form a sort of pavement. There are three in the first row, the anterior of which responds to the radius, the posterior to the ulna, and the intermediate one to both radius and ulna. In the second row there are four, the anterior of which is the smallest. Under this anterior bone, which may be also taken for a metacarpal, is a pointed bone which is the sole vestige of a thumb. The next bone, which is the fore finger, is composed of nine joints, which must represent its metacarpal, its phalanges, and their epiphyses: there are seven in the third finger and four in the fourth; the fifth is reduced to a single very small tubercle.

In the Narwhals the skull resembles that of the Dolphins, and especially the head of the *Beluga*, in structure; but instead of the numerous teeth ranged along the maxillaries presented by the Dolphins generally, there is but one on each side, directed forwards and implanted in an alveolus common to the maxillary and intermaxillary bones. Very rarely indeed are these teeth symmetrical; and nearly always one of the two remains inclosed in its alveolus, whilst the other grows to a length of ten or twelve feet. The muzzle, and more especially the intermaxillary bones, are more widened than in the Dolphins. The intermaxillaries ascend near to the bones of the nose. The holes with which the maxillaries are pierced in their widened part, and which occupy the place of the suborbital holes, are large and numerous. The notch which separates this widened part from the muzzle is small, and the upper part of the orbit projects but little. The nasal are very small, and the left nostril is smaller than the other.



Skull and Teeth of Narwhal (*Monodon monoceros*), seen from below. Owen.

The number of vertebræ, according to Scoresby, are—7 cervical, 12 dorsal, and 35 lumbar or caudal—54 in all. The spinal canal is said to cease at the forty-first. The spinous apophyses begin to diminish at the thirty-fourth, and disappear at the thirty-eighth. The V-shaped bones commence between the thirtieth and the thirty-first, and terminate between the forty-second and forty-third. There are six pairs of true ribs and six false, all rather slender. The bones of the anterior extremity appear to bear a close resemblance to those of the Porpesse, except that the bones are more equal, as might be expected from the roundness of the Narwhal's flipper.

In the Hyperoodons the skull differs almost entirely in form from those belonging to the Dolphins. From the maxillaries, which are pointed in front and widened towards the base of the muzzle, rises on each of their lateral borders a large vertical crest, rounded above, descending obliquely forwards and more rapidly backwards, where it falls again nearly above the postorbital apophysis. Still more backwards, the maxillary bone, continuing to cover the frontal bone, ascends vertically with it and with the occipital, to form on the back part of the head a transverse occipital crest, which is very elevated and very thick, so that on the skull of the animal there are three of these great crests: the occipital crest behind, and the two maxillary crests on the sides, which are separated from the first by a wide and deep notch. They do not approximate above, nor do they form a vault, as in the Dolphin of the Ganges, but simply a sort of lateral walls. The intermaxillaries, placed as ordinarily between the maxillaries, ascend with them to the nostrils, and passing by the side of them, raise themselves above, so that they take part in the formation of the posterior crest elevated upon the occiput. The two nasal bones, which, as well as the nostrils, are very unequal, are placed at the anterior surface of this occipital crest, and are raised to its summit. In other respects the connections of the bones are nearly the same as in the Dolphins.

The zygomatic apophysis of the temporal bone is thick, without being as long as in the Dolphin of the Ganges; the orbit is as wide as in the ordinary Dolphins, and bounded in like manner below by a slender stem given off by the jugal bone. The parietal bones show themselves but very little in the temporal fossa, which is itself not much extended in height. Below, the palate is slightly carinated, indicating an approximation to the *Balænæ*. The lateral furrows observable in the common Dolphin are absent. The pterygoideans occupy a very great length in the back-nostrils, and much diminish the portion which the palatine bones fill in front. The vomer shows itself at two points of the lower surface, between the pterygoideans and the palatines, and between the maxillaries and intermaxillaries. The occiput is higher than it is wide. The lower jaw has not the symphysis longer than in the ordinary species of the Dolphins.

The seven cervical vertebræ are all anchylosed together; there are thirty-eight other vertebræ, nine of which carry the ribs. At the twenty-second the V-shaped bones which characterise the first caudal commence, so that seventeen caudal vetebræ may be counted. There are six of these V-shaped bones; and the superior spinous apophyses cease on the ninth caudal. The five first ribs only are articulated to the sternum, and there are only four false ribs on each side. The sternum is composed of three bones, the first square, notched in front and behind; the second square also, and notched in front; the third oblong and notched behind.

The shoulder-blade has the spinal border more extended in proportion and more rectilinear than in the Dolphins, the anterior angle more pointed, the acromion directed rather downwards, and the coracoid process a little in the opposite direction. The bones of the arm and fore-arm are a little less shortened than in the Dolphins. ('Ossemens Fossiles.')

The skull of the Cachalots bears a nearer resemblance to that of the Dolphins than to that of any other Cetaceans. The immense muzzle, notwithstanding its prodigious extent, is, like that of the Dolphin, formed by the maxillaries on the sides, the intermaxillaries towards the mesial line, and the vomer on that line. The intermaxillaries reach beyond the other bones to form the anterior point; they ascend on the two sides of the nostrils and the nasal bones, and raise themselves to form that species of wall which elevates itself perpendicularly and circularly on the back of the head, but that of the right side is carried higher than that of the left. The vomer shows itself between them in considerable width, especially at the upper part; it is hollowed into a semicanal throughout its length. The nostrils are pierced at the foot of this sort of wall at the root of the vomer, and between the raised and ascending parts of the tw[illegible]maxillaries. Their direction is oblique from below upwards, and from behind forwards. They are excessively unequal, and that on the right side is not a fourth of the size of that on the left. The nasal bones are also very unequal. Both ascend between the intermaxillaries against the foot of the semicircular wall which is raised upon the cranium, but they only rise to the level of the left intermaxillary. The right nasal bone is not only larger than the other, but it also descends lower between the two nostrils, articulating itself upon the root of the vomer, and giving to that part an irregular crest which reposes a little obliquely on the left nostril, which, as before observed, is the longest.

The direction of the vomer and amplitude of the left nostril indicate a direction of the membranous canal of the nostrils and the whole spouting apparatus towards the same side, and explain, Cuvier observes, the fact observed by mariners, namely, that the Cachalots throw their spoutings towards the left side.

The maxillaries do not join each other in front of the semicircular wall; and leave exposed between them an irregular and considerable part of the frontal bone, which goes behind them, and directing itself laterally, proceeds to form, as in the Dolphins, the principal part of the ceiling of the orbit. The maxillary makes its anterior angle, in front of which the border of the maxillary has a deep notch, and at its upper surface, opposite to that notch, is the great hole which occupies the place of the suborbital, but which, Cuvier remarks, should here be called supra-orbital. The posterior angle of the orbit is occupied by the point of the zygomatic apophysis of the temporal bone; but it does not quite join the postorbital apophysis of the frontal bone, so that the edge of the orbit is open at this point. The lower part of the orbit is formed by a stout and cylindrical jugal bone, whose anterior part dilates itself into an oblong lamina which partially closes the orbit in front. The temporal fossa is very deep, rounded, but not distinguished by a crest from the rest of the occiput: a little of the parietal bone is perceptible between the temporal and the frontal bones. The squamous portion of the temporal bone is not extensive, its zygomatic portion is in the shape of a stout and short cone; proceeding to the orbit it alone forms the arch as in the Dolphins. The occipital bone is vertical and forms the whole posterior surface of the semicircular wall which surrounds the skull behind. The occipital hole is nearly at the lower third of its height. The lower border of the occipital bone is divided on each side by a notch into two lobes, the external of which represents the mastoid apophysis.

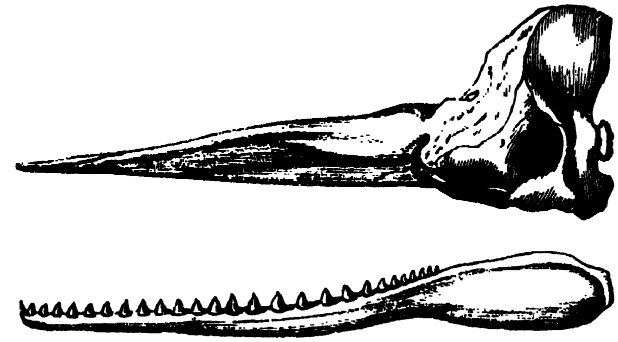
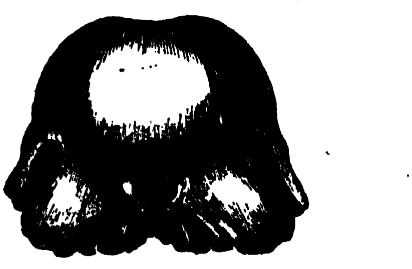
Skull of Cachalot, seen obliquely from above.



Profile of Skull of Cachalot and under jaw.



Skull of Cachalot, seen from behind.

The lower part of the skull, allowing for the difference of proportion of the parts, much resembles the lower portion of that of the Dolphins. The region behind the nostrils is very much shortened in comparison of that which is anterior to them, and of which the enormous muzzle forms the greatest portion. The result of this conformation is that the basilary and posterior sphenoid are very short; that the anterior sphenoid, as in the Large-Muzzled Dolphins, only shows itself below in a notch of the vomer, and appears very little towards the temple between the palatine, the pterygoidean, and the temporal ala of the posterior sphenoid; and that the pterygoideans extend on their lateral and posterior part, nearly to the posterior portion of the basilary bone. The jugal bone on its anterior part lines below a great portion of the vault of the orbit, and proceeds to touch behind the points of the two sphenoids. Their anterior border is not double, as in the Dolphins. The bone of the ear bears a great resemblance to that of the Dolphins, but the tympanic bone is less elongated and less lobated backwards.

Of the cervical vertebræ of the Cachalot the atlas alone is distinct; the six others are anchylosed into a single mass by the bodies and spinous apophyses; but the number may be made out by the sides where very delicate laminæ interpose between the holes where the nerves pass out. There are 14 pairs of ribs and 14 dorsal vertebræ (perhaps a fifteenth), and 35 others. The dorsal vertebræ have their transverse apophyses short; their anterior articular apophyses are turned inwards, and embrace the posterior, which look outwards. The spinous processes are less elevated and wide from before backwards. The two last carry the ribs only on the extremity of their transverse apophyses, and not on a facet of their body. On the succeeding vertebræ the spinous apophyses rise, become oblique, and wider at their summit than at their base. The articulars ascend gradually to their anterior borders, as in the Dolphins: the spinous apophyses shortening by degrees, the articular apophyses arrive at their summit on the tail, and finally disappear. The spinous apophyses disappear also on the last caudal vertebræ. The transverse apophyses are at first simple tubercles of the articular apophyses: they do not take the form of distinct apophyses till the three last dorsal vertebræ, and afterwards continue on the lumbar and caudal, but always remaining of moderate length, and not dilating at their extremity. The lower part of the body of the vertebræ, counting from the fourth lumbar, is strongly carinated. The V-shaped bones do not commence before the twenty-first after the dorsal vertebræ. They are at first rather long, and more so than the spinous apophyses to which they correspond; but afterwards they are a little shortened. The vertebræ which carry them have their lower carination divided into two truncated ridges, each at the two extremities, so as to form facets for the V-shaped bones, which always articulate between two vertebræ. The caudal vertebræ still remain very large up to the six or seven last, which diminish rapidly, losing their different eminences: thus the greatest portion of the spine is nearly much of a size.

The shoulder-blade is concave externally, convex on the side of the ribs, and narrower than in the other Cetaceans: its spinal border is not two-thirds of its height. Its anterior border becomes double below the middle of its height, and gives off from its external ridge a great acromion, more projecting anteriorly than the shoulder-blade is at this point, and enlarged at its extremity. The internal border gives off near the articular head a coracoid apophysis, which projects less than the acromion, and terminates in a point. The humerus is very short and stout, and has at its anterior border a crest, terminated towards the lower part by a hook which represents the deltoidal crest. The ulna is anchylosed early to the humerus, even before the epiphysis of this last is united. The olecranian apophysis projects very much, and curves towards the wrist. ('Ossemens Fossiles.')

Balænidæ, or Whalebone Whales.—The skull of the Rorqual (*Balænoptera*) is more approximated to that of the Dolphins than the skull of the *Balænæ*, properly so called. The immense maxillary bones are disposed below, in form of a reversed roof or a keel, to the two sides of which the baleen, or whalebone, is attached. The vomer is shown between them in nearly the mesial line of the keel. Above, the two intermaxillaries, placed parallel between the two maxillaries, leave between them a vacant space, which is continued above, or rather backwards, with the very large aperture of the nostrils, which is in the form of an elongated oval; and, contrary to the other Cetaceans, preserves, as in the whole of the *Balænæ*, a symmetrical form. The nasal bones, which are short, but notched or festooned anteriorly, and not in form of tubercles, form the upper border of this aperture. The maxillary does not cover the frontal bone, except by a narrow apophysis on the two sides of the nasal bones. The whole portion of the frontal bone which goes on each side to form the orbit is exposed, but the parietal bones cover the upper part of the temporal fossa to the sides of the apophysis of the maxillary bone, which shows itself between the frontal and the bones of the nose. The occipital bone advances between them, and covers the middle of the frontal to near the bones of the nose; so that at the base of the nose the frontal does not show itself externally. There are two temporal crests projecting greatly outwards, commencing at the sides of the nose, and between which the skull is flat, or even slightly concave, and descends slowly towards the occipital hole, which is at the extremity of this plane. The occipital crest comes near the base of the nasal bones, traversing from one temporal crest to the other. On the middle of this occipital surface is a slightly projecting longitudinal ridge.

The jugal bone is curved into a portion of a circle, and forms the lower border of the orbit, coming from the zygomatic apophysis of the maxillary bone, which abuts at the anterior angle on the temporal apophysis, which abuts on the posterior angle. The jugal bone is not dilated at its extremity as in the Dolphin. The frontal on one side touches the maxillary, and on the other the temporal bones, by its ante- and post-orbital apophyses, and forms by itself the whole ceiling of the orbit, without being doubled above by the maxillary; but on the contrary it is below, on its anterior portion, that in front of the orbit, and moreover is bordered there anteriorly by the lateral lamina of the maxillary bone, which is, with reference to the frontal, in an inverse position from that which it holds in the Dolphins. It is by this lamina that the maxillary bone abuts on the anterior angle of the orbit, and articulates itself with the anterior and enlarged extremity of the jugal bone; but what is very remarkable is, that at this point, between the frontal and the maxillary, and, so to speak, at their very articulation, a peculiar bone, in form of a lamina, occupies nearly half the length of that suture, and which perhaps is the analogue of the lachrymal bone. The whole of the zygomatic arch, properly so called, which is very large, belongs to the temporal bone. The frame of the orbit is closed on all sides; its ceiling is very large and concave above. The palatine bones are prolonged below the keel of the maxillaries. The posterior nostrils are very near the occipital hole. They have at each angle a tuberosity formed by the pterygoidean bone, which has little longitudinal extent, and only surrounds the nostrils on the external side and a little above and below, but without forming a sinus or double border there, as in the Dolphins. The basilary region, which is very short, is also hollowed into a canal, as in them, and has on each side the bones of the ear, which are very small in proportion, and of oval form, and equally convex in their inferior surface. In front of the basilary bone, and between the pterygoidean bones, may be seen the body of the posterior sphenoid. The glenoid face of the temporal bone is nearly vertical, and looks forwards; that which makes the articular surface of the lower jaw is in some sort the truncature of the extremity of the bone. This jaw is an arch externally convex, compressed, slightly trenchant above and below. It has a coronoid apophysis in form of an obtuse angle, and a tuberosity a little more backwards.

Cuvier points out certain differences between the skulls of the Rorquals of the Cape, the Mediterranean, and the North Sea, for which we must refer the reader to his 'Ossemens Fossiles.'

Balæna.—To form the idea of a *Balæna*, properly so called, Cuvier states that we must figure to ourselves the muzzle of the Rorqual narrowed, elongated, compressed laterally, and arched from before backwards, nearly in a quarter of a circle. It is, he observes, in the space which this curvature leaves, that the plates of baleen, or whalebone, which adhere by their upper and wide extremity to the sides of the keel which the muzzle forms below, and descend obliquely outwards by their lower and pointed extremity towards the lower jaw, are lodged. It is precisely because this curvature gives them more space in the *Balænæ*, properly so called, that they are longer in those whales than in the Rorquals, in which last the nearly straight muzzle leaves them little room.

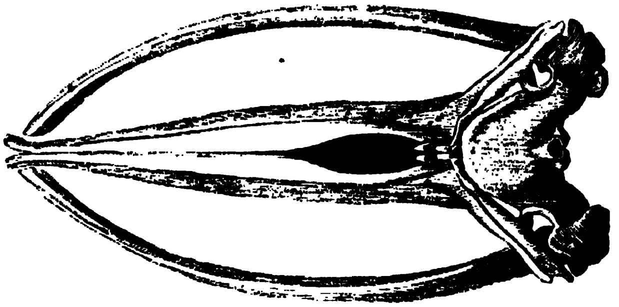
It results from this lateral compression of the muzzle that the intermaxillary bones are not horizontally between but vertically upon the maxillaries: the upper plane of these last is itself nearly vertical, except in the lateral branch, which borders the frontal before, to proceed with it upon the orbit. This transverse portion of the frontal bone is narrower from before backwards than in the Rorqual. The occipital bone is convex throughout its upper portion, less oblique than in the Rorqual, and semi-oval. The temporal bone remains transverse, and its zygomatic portion hardly curves forwards at all. The nasal bones are rhomboidal, and not triangular as in the Rorqual. Below, the palatine and pterygoidean bones are thrown still more back, and are shorter, and the sphenoid bone is more concealed than in the Rorqual. The maxillary bone has a deep notch at its lower and posterior border. The glenoid surface of the temporal bone is much less vertical than in the Rorqual, so that the lower jawbone rises a little to offer its articular convex surface. This disposition, joined to the absence of a coronoid apophysis, may serve to distinguish it from the lower jaw of the Rorqual.

In the Rorqual of the Cape, Cuvier found the atlas distinct from the axis; this last is anchylosed by the upper part of its ring, which has no spinous apophysis, with the corresponding part of the third cervical. This last and the four others do not unite: they are of some thickness. The transverse apophyses are double in the first three, as in the axis; one superior is given off from the annular portion below the articular apophysis, the other from the lower part of the body; none of these apophyses are directed forwards. The lower are shortened from the axis to the fourth vertical and are wanting in the succeeding ones. The upper apophyses are longest on the axis and on the third; afterwards they are equal, and form a series with the transverse apophyses which carry the ribs. There are 7 cervical vertebræ, 14 dorsal vertebræ and as many pairs of ribs, and 31 other vertebræ to the end of the tail—52 in all. The second, third, and fourth ribs only have heads, and seem hardly able to reach the body of the vertebræ. The others only reach the extremities of the transverse apophyses, which go on lengthening to the lumbar region. They are longer than they are wide, and dilate at the end, as in the Greenland Whale. They thus continue to the thirteenth lumbar, where they begin to shorten, but still widen to the fifteenth or sixteenth, where they disappear. The spinous apophyses begin to show themselves on the third cervical. They remain small on the neck, and begin to be elongated and compressed on the first dorsals. They form a nearly equal series; wider on the middle of the back, narrower, but always moderately elevated, on the lumbar region, and shortening by degrees on the tail. They vanish on the last twelve, and the annular portion disappears two vertebræ after the spinous apophyses. The facets of the articular apophyses look inwards as far as the eleventh, where they begin to open outwards. They do not rise, and finally form, towards the fourteenth or fifteenth, with the spinous (which is always shortened), a trilobated prominence. The pelvis in the French skeleton is attached under the ninth lumbar vertebra. At the eleventh the V-shaped bones commence. The first is still formed of two separate bones. They re-divide anew behind. The lower part of the lumbar and caudal vertebræ is hardly marked by a slight carination. Commencing from the fifteenth vertebra after the dorsal, the body of each is pierced on both sides, above and below, with a large hole for the vessels. These holes do not diminish on the last caudal, though they are much smaller, so that they each represent two cylinders set back to back, pierced in their axis.

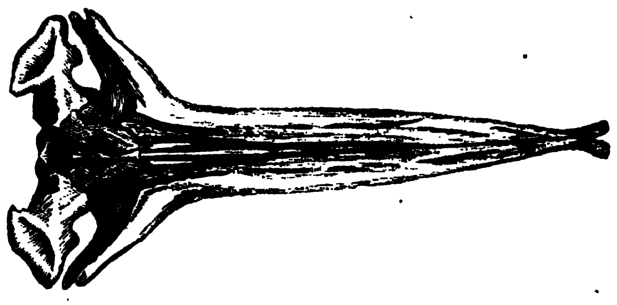
The single bone of the sternum was square, deeply forked posteriorly, and with a point at its external border.

The shoulder-blade of the Cape Rorqual is, Cuvier remarks, entirely different from that of the *Balæna*; it is wider than it is long, semicircular on the spinal side, with a single anterior border, a single prominence (the acromion) towards the lower third, and a tubercle near the articulation, which is the coracoid apophysis. The humerus is still stouter in proportion than that of the *Balæna*, but the bones of the fore-arm are much more elongated. The fin is also much more pointed. There are only four well-marked fingers, which, not counting the metatarsals, have the following joints: the index two, the middle and ring-finger seven each, and the little finger three: all the fingers are terminated by a cartilaginous dilatation.

The bone of the ear in the *Balænæ* differs from that of the Dolphins in the enormous thickness of the tympanic bone, especially on the internal side. The tympanic bone is a little more closed in front, but leaves between it and the petrous bone on the internal side a solution of continuity wider and longer in proportion. It is not bilobated backwards. The petrous bone is of very irregular form, and very rugged; it gives off two great and stout apophyses, also very rugged, one of which, posterior and a little superior, articulated to a corresponding apophysis of the tympanic bone, is inserted between the temporal and lateral occipital; and the other, anterior and inferior, is articulated by squamous suture with the temporal portion, which descends to furnish articulation with the lower jaw. The ear-bones in all the Cetaceans are four in number, as in the *Mammalia*, and the malleus is anchylosed to the frame of the tympanum, which, Cuvier observes, is the more singular, inasmuch as it is not deprived of its muscles.

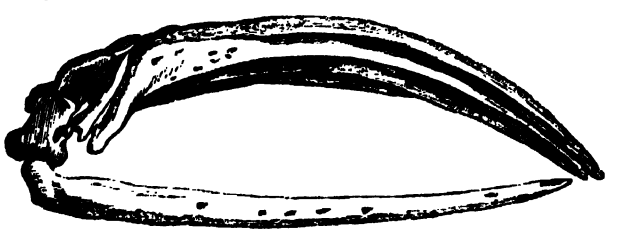


Skull of Greenland Whale, with lower jaw, seen from above.



Skull of Greenland Whale, seen from below.

Cuvier remarks, that the skull of the Greenland Whale differs more from the *Balæna* of the Cape than the skulls of the Rorquals differ from each other. He points out these differences, which extend, although slightly, to the bones of the ear; and expresses his opinion that they are different species.



Skull of Greenland Whale, with lower jaw, profile.

In the great Cape *Balæna*, according to Cuvier, the atlas, the axis, and the five other cervical vertebræ are united together by their bodies. All their spinous apophyses are anchylosed into a single crest. The atlas and axis unite besides by their upper transverse apophyses, which are wide and strong: their lower transverse apophyses, which are equally long and strong, are anchylosed to each other and to that of the third, which is more slender. The next four cervicals have only delicate transverse apophyses, of which the third, fourth, and fifth are anchylosed together. The last also has only one upper transverse apophysis, but longer, stronger, free, and directed forwards. Cuvier remarks that this division of the apophyses into upper and lower responds to the two branches separated by a canal, which are seen in those of ordinary mammals. The transverse apophyses of the first dorsal are directed also forwards, and are long and a little stronger than at the last cervical; they commence increasing in bulk, and shortening at the fourth dorsal. The succeeding take a more transverse direction, and are enlarged at the end, to the tenth inclusive. Counting from the eleventh, they again begin to elongate to the seventeenth; they then diminish insensibly to the thirty-fourth, where they disappear. They are throughout longer than in the Cachalot, and enlarged towards the end, the contrary of which is manifested in that genus. There are fifteen pairs of ribs; the last four pairs and the first two do not reach the body of the vertebra, and are only attached to its transverse apophysis. The first pair is flattened and extremely wide, especially at the sternal extremity. The last three are slender and short. After the fifteen dorsal vertebræ come twenty-seven others. The V-shaped bones commence between the eleventh and twelfth; they are small compared with those of the Cachalot, and disappear after the twenty-sixth. The eleven or twelve last vertebræ have no longer any eminences. The last of all are nearly quadrangular, and are each pierced with two vertical holes. The spinous apophyses form a tolerably uniform series of moderate height, all inclined forwards; they begin to diminish on the tail. The anterior articular apophyses are not elevated, remain at the same height, and preserve the same dimensions. They widen on the tail where they have no articulation to furnish, and the last five or six, nearly equal to the corresponding spinous apophyses, form with them on their vertebræ a trilobated prominence.

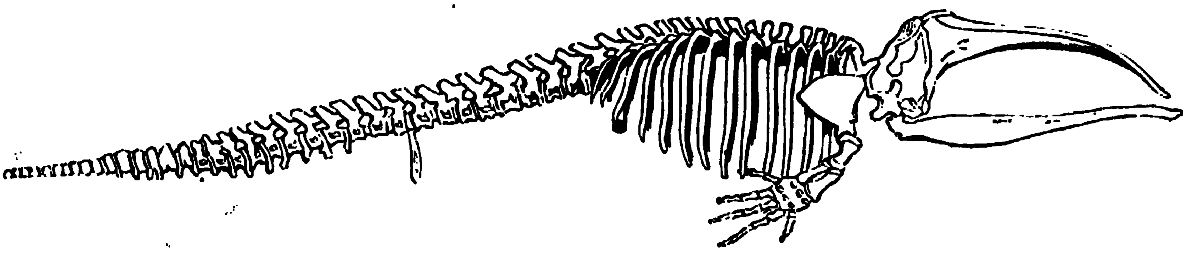
The single bone of the sternum was oblong, widest in front, and carried on each side an articular facet for a rib.

The shoulder-blade is nearly flat; one can scarcely perceive a slight concave curvature: it is nearly fan-shaped, and less wide than high. Its anterior border is simple, and has only a single projecting apophysis, which from its position is probably the acromion. Its articular head is much wider in proportion than in the Cachalot. The humerus is stout and short, scarcely twice as long as it is thick. Its tuberosity does not reach beyond the head in front; this last is hemispherical, and nearly parallel to the axis. The lower head is divided into two slightly inclined planes for the ulna and radius, which two bones are compressed; the ulna is the narrowest, especially in its middle. Its upper head is slightly oblique at its axis, and the olecranon ascends a little instead of recurving into a hook, as in the Cachalot. The radius enlarges below, so as to be there two-thirds of its length; above it is not more than a third. There are four carpal bones in the first row, of which the ulnar bone, which responds to the pisiform, forms a projection externally: there are only three in the second. The metatarsals are in length only double their width. The thumb has two phalanges, the ring-finger four, the little finger three; and all are terminated by a cartilaginous dilatation. A wide and short fin obliquely rounded is the result. ('Ossemens Fossiles.')

The pelvis in the Cetaceans is, as we have seen, only rudimentary; but it may be necessary here to give a summary of the modification of the bones and their connection with the skeleton in the different groups.

In the Dugong it consists of two pairs of bones joined two and two, and end to end, by a cartilage: to the vetebræ this apparatus is attached by a cartilage also.

The construction of this part varies in the true Zoophagous Cetaceans. Two small long bones lodged in the flesh, one on each side of the anus, form the pelvic rudiments in the Dolphins. In the great whales, the Mysticete, or Whalebone Whale, for example, at the extremity of each of the bones, regarded by comparative anatomists as ilia, a second, which is smaller and curved, is articulated. The convexity of this last bone is external, and may be considered as a pubis or ischium.



Skeleton of Mysticete, or Whalebone Whale.

Digestive Organs.—Phytophagous Cataceans.—The teeth (molars) of the Manatees are ridged doubly or trebly, the root distinct from the crown: here the resemblance to the pachyderms, Tapir and Hippopotamus for instance, is very strong. The molars of the Dugongs are elliptical, without true fangs, and with two slight furrows on the unworn crown, which disappear with age. In the upper jaw are two tusks. In the *Rytinæ* there are no molars; but there is in lieu of them a horny plate in the middle of each jaw. The tongue is short, and can hardly be endowed with much motion. The form of the os hyoides is simple: anchylosis between the body and posterior cornua soon supervenes; but the latter send no ligament to the thyroid cartilage. The anterior cornua remain generally cartilaginous, and are the medium of union between the body, or basi-hyal, and the large and long styloid processes.

Professor Owen states that the opening of the larynx is chiefly defended, during the submarine mastication of the vegetable food of the Dugong, by the extreme contraction of the faucial aperture, which resembles that of the *Capybara*. No pyramidal larynx traverses it, as in the true *Cetacea*. Two large parotid glands are situated immediately behind the large ascending ramus of the lower jaw. A thick layer of simple follicular glands is developed above the membrane of the palate, and a glandular stratum is situated between the mucous and muscular coats of the lower part of the œsophagus. Professor Owen states that a similar but more developed glandular structure is present in the œsophagus of the Ray. He then observes that the stomach of the Dugong presents, as Sir Everard Home had justly observed, some of the peculiarities met with in the Whale Tribe, the Peccari and Hippopotamus, and the Beaver: like that of the first it is divided into distinct compartments; like the second and third it has pouches superadded to and communicating with it; and like the last it is provided with a remarkable glandular apparatus near the cardia. These modifications, the Professor remarks, obviously harmonise with the difficult digestibility and low-organised matter of the food of the Dugong. "Yet," says he, "it is a fact that would not have been à priori expected, that in the Carnivorous *Cetacea* the stomach is even more complicated than in the Herbivorous species, and presents a closer resemblance to the ruminant stomach; it is divided, for example, into a greater number of receptacles, and has the first cavity like the rumen lined with cuticle; while in the Dugong, on the contrary, the stomach is properly divided into two parts only (of which the second much more resembles intestine), and both are lined with a mucous membrane." After a luminous detailed account of the stomach, Professor Owen observes that it would seem that a cæcum—and he minutely describes that of the Dugong—is present in all the Herbivorous *Cetacea*: for Steller notices it as of large size and sacculated in the Northern Manatee (*Stellerus*); and Daubenton has given a figure of the bifid cæcum in the Southern Manatee (*Manatus Americanus*). It is interesting, he adds, to find that a caput coli (the situation and structure of which in the Dugong he describes) is present in the true *Cetacea*, as the *Balænidæ*, which subsist on animal food of the lowest organised kind. The whole of the alimentary canal and the individual differences presented by the three specimens having been elaborately detailed, Professor Owen proceeds to point out that the Dugong with respect to the biliary organs deviates in a marked degree from the ordinary *Cetacea*, in the presence of a well-developed gall-bladder, an organ which Daubenton also found in the Manatee. But the presence of the gall-bladder is not, the Professor observes, constant in the Herbivorous *Cetacea*; for in the Northern Manatee, according to Steller, it is wanting, and its absence seems to be compensated by the enormous width of the ductus communis choledochus, which would admit the five fingers united. The secretion of the pancreas was carried by from twenty to thirty ducts, each about two lines in diameter, to a very wide common excretory canal, which terminates below, but on the same prominence with the cystic duct, at a much greater relative distance from the pylorus than in the true *Cetacea*. In one of the Dugongs dissected by Professor Owen were two small accessory spleens in addition to the larger rounded one, but in the other specimens the last alone was present. ('Zool. Proc.,' 1838.)

Zoophagous Cetaceans.—The teeth of the Dolphins are generally simple and conical or compressed. They are present in both jaws; their number varies, and they not unfrequently lie hid in the gums in a rudimentary state. Those of the Cachalots are simple, of a long ovoid recurved shape, and placed in the lower jaw only. The Mysticetes, or Whalebone Whales, are without true teeth; in lieu of which, transverse horny plates of baleen, or whalebone, as it is commonly termed, grow from the palate. Those plates on their internal edges are fringed with loose beards, and among these the small marine animals which form their food are entangled as in the meshes of a net.

The stomachs of the Zoophagous Cetaceans are very complicated: the number of these in various species, and in different individuals of the same species, has been variously given by different authors. Some have stated the number in the common Dolphin and Porpesse at three, others at four, others at five, others at six. F. Cuvier considers it as certain that these numerical differences proceed simply from the manner in which the organ is viewed. Professor Owen was unable to distinguish more than four compartments in the stomach of the Porpesse. In general the spouting whales have no cæcum; but a trace of it has been found in the Platanist, and it actually exists in the Piked and Whalebone Whales.

John Hunter pointed out the considerable degree of uniformity present in the liver of this tribe, observing that in shape it resembles that of man, but that it is not so thick at the base nor so sharp at the lower edge, and probably not so firm in the texture. The right lobe is the largest and thickest. There is no gall-bladder. The same distinguished comparative anatomist describes the pancreas as a very long flat body, having its left end attached to the right side of the first cavity of the stomach: it passes, he adds, across the spine at the foot of the mesentery, and near to the pylorus joins the hollow curve of the duodenum, along which it is continued and adheres to the intestine, its duct entering that of the liver near the termination of the gut. In the Piked Whale the spleen is single and small; in the Porpesse it is subdivided into several distinct portions.

There is an interesting series of preparations illustrative of the anatomy of the *Cetacea* in the museum of the College of Surgeons, and well deserving the attention of the student of comparative anatomy. One of these preparations, No. 323, is a perpendicular section of several plates of whalebone, with the intermediate substance and vascular nidus, from the upper jaw of a young specimen of the Great Whale (*Balæna mysticetus*, Linn.). The disposition and relative proportions of the plates of whalebone are here shown; from which disposition it results, that only the fringed extremity of the whalebone plates are visible from the inside of the mouth of the whale; the whole concavity of the palate appearing to be beset with coarse rigid hairs or bristles, which explains the passage in Aristotle ('Hist Anim.' iii. 12), who, speaking of the Great Whale ('*μυστικητος*, or, as Bekker reads it, *ὁ μῦς τὸ κῆτος*), says, "The Mysticete has no teeth in its mouth, but hairs like hog's bristles."

Circulating System.—Phytophagous Cetaceans.—The three Dugongs dissected by Professor Owen presented the same remarkable extent of separation of the two ventricles of the heart described by Sir Everard Home and Sir Stamford Raffles in the individuals examined by them, and observed by Rüppell in the Dugong of the Red Sea (*Halicore Tabernaculi*). Daubenton appears to be the first who noticed this condition of the heart, in his dissection of the fœtus of the Manatee. Steller also described it in the genus which bears his name; but in that animal the apical cleft of the heart extended upwards only one-third of the way towards the base, whereas in the Dugong it reaches half-way towards the base.

Professor Owen found the foramen ovale completely closed, and the ductus arteriosus reduced to a thick ligamentous cord, permeable for a short distance by an eye-probe from the aorta, where a crescentic slit still represented the original communication. He states that in the smoothness and evenness of their exterior and their general form the auricles of the Dugong resemble those of the Turtle (*Chelone*), and that the appendix can hardly be said to exist in either. The right auricle is larger than the left. The primary branches from the arches of the aorta correspond in each specimen with Sir Everard Home's figure and description. There was only one superior cava, not two, as in the Elephant; and the pulmonary veins terminated in the left auricle by a common trunk an inch in length.

As no mention had been made in the anatomical descriptions of the Herbivorous Cetaceans by Daubenton, Steller, Cuvier, Raffles, and Home, respecting the existence or otherwise of the extraordinary intercostal and intervertebral arterial plexuses present in the true *Cetacea*, Professor Owen carefully followed out this part of the dissection, but could detect no trace of this very striking modification. Here again, he observes, in enunciating a general anatomical proposition regarding Cuvier's *Cetacea*, the Herbivorous species must be exceptionally cited apart.

Zoophagous Cetaceans.—Professor Owen remarks that the Carnivorous Cetaceans do not participate in the structure of the heart above described with the Herbivorous section.

The following is John Hunter's description of the heart of the Whale:—

"The heart is inclosed in its pericardium, which is attached by a broad surface to the diaphragm, as in the human body. It is composed of four cavities—two auricles and two ventricles: it is more flat than in the quadruped, and adapted to the shape of the chest. The auricles have more fasciculi, and then pass more across the cavity from side to side, than in many other animals; besides being very muscular they are very elastic, for being stretched they contract again very considerably. There is nothing uncommon or particular in the structure of the ventricles, in the valves of the ventricles, or in that of the arteries. The general structure of the arteries resembles that of other animals; and where parts are nearly similar, the distribution is likewise similar. The aorta forms its usual curve, and sends off the carotid and subclavian arteries. The veins, I believe, have nothing particular in their structure, excepting in parts requiring a peculiarity, as in the folds of the skin on the breast in the Piked Whale, where their elasticity was to be increased."

This assertion respecting the vei[illegible] not stated very positively, and we shall presently see that there is a peculiarity in their structure.

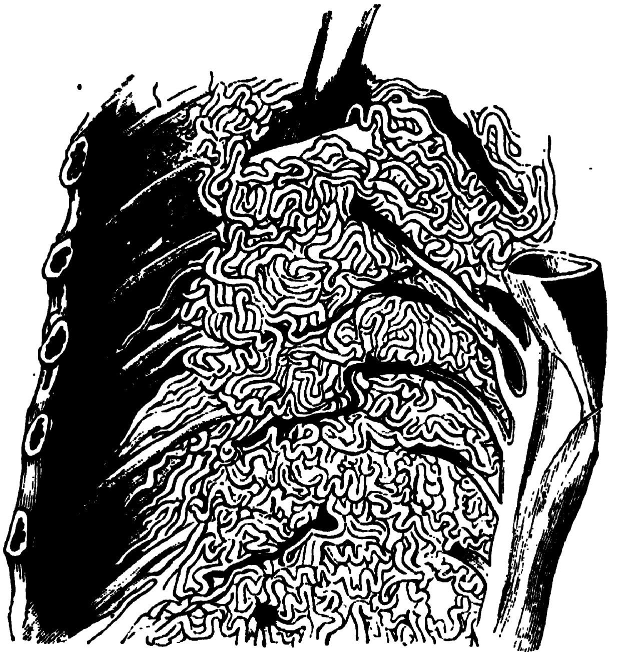
The same great physiologist well observes, that in our examination of particular parts, the size of which is generally regulated by that of the whole animal, if we have only been accustomed to see them in those which are small or middle sized, we behold them with astonishment in animals so far exceeding the common bulk as the Whale. "Thus," says Hunter, "the heart and aorta of the Spermaceti Whale appeared prodigious, being too large to be contained in a wide tub, the aorta measuring a foot in diameter. When we consider these as applied to the circulation, and figure to ourselves that probably 10 or 15 gallons of blood are thrown out at one stroke, and moved with an immense velocity through a tube of a foot diameter, the whole idea fills the mind with wonder."

But the most remarkable modification of the arterial system in the Whales remains to be noticed. This consists in an almost infinite circumvolution of arteries, forming a plexus of vessels filled with oxygenated blood, situated under the pleura and between the ribs, on each side of the spine. This intercostal plexus, or rete mirabile, is the apparatus which enables the whale to remain under water for more than an hour.

M. Breschet read a paper to the French Academy of Sciences in 1834, which bears the following title: 'Histoire Anatomique et Physiologique d'un Organe de Nature vasculaire *découvert* dans les Cétacés, etc.' M. Breschet has however no claims to the discovery of this organ. It was indicated and described long ago by Tyson in his 'Anatomy of a Porpesse,' but he was not aware of the use of it, and considered it as a glandulous body. Hunter was the first who determined its exact nature, and showed that it was a reservoir of arterial or aërated blood.

After noticing the general structure of the arteries as above mentioned, and stating that the aorta forms its usual curve, sending off the carotid and subclavian arteries, Hunter proceeds as follows:—

"Animals of this tribe, as has been observed, have a greater proportion of blood than any other known, and there are many arteries apparently intended as reservoirs, where a large quantity of arterial blood seemed to be required in a part, and vascularity could not be the only object. Thus we find that the intercostal arteries divide into a vast number of branches, which run in a serpentine course between the pleura, ribs, and their muscles, making a thick substance, somewhat similar to the spermatic artery in the Bull. These vessels, everywhere lining the sides of the thorax, pass in between the ribs near their articulation, and also behind the ligamentous attachment of the ribs, and anastomose with each other. The medulla spinalis is surrounded with a net-work of arteries in the same manner, more especially where it comes out from the brain, where a thick substance is formed by their ramifications and convolutions; and these vessels most probably anastomose with those of the thorax. The subclavian artery in the Piked Whale, before it passes over the first rib, sends down into the chest arteries which assist in forming the plexus on the inside of the ribs. I am not certain but the internal mammary arteries contribute to form the anterior part of this plexus. The motion of the blood in such cases must be very slow; the use of which we do not readily see. The descending aorta sends off the intercostals, which are very large, and gives branches to this plexus; and when it has reached the abdomen it sends off, as in the quadruped, the different branches to the viscera and the lumbar arteries, which are likewise very large, for the supply of that vast mass of muscles which moves the tail."



Arterial Plexus in the Dolphins. Breschet.
